The observations and clinical experience of Drs. Contal and Vidal account for and explain the rationale of the success which I have attained in the treatment of ulcerated and inflamed tonsils and inflammation of contiguous structures by the combined application of ether and iodoform in the form of spray. The value of iodoform in the treatment of inflamed and ulcerated surfaces is now too well known to need more than mention. The little punctures claimed by Dr. Vidal as "hastening the anæsthetic action of the ether spray" find a parallel in the ulcerated points of the inflamed surfaces, both of tonsils and surrounding mucous membranes. I think I am not exaggerating in claiming that iodoform and ether combined, and applied locally in the form of spray, may fairly be regarded as a specific in the treatment of sore and ulcerated throat, tonsils, and contiguous structures.

MORRIS H. HENRY.

581 FIFTH AVENUE, NEW YORK.

WHITE LEAD PAINT AS A LOCAL DRESSING IN ERYSIPELAS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In your issue of April 14, 1883, an article from the *Lancet* urged the employment of white lead paint as a local dressing in erysipelas, and this article called forth several communications, all testifying to the usefulness of the carbonate of lead.

In the number of THE RECORD published on August 18th, another article, from the *Lyon Medical*, records four cases of erysipelas which were successfully treated with hypodermic injections of resorcin.

Unfavorable or negative results are seldom published, but the following cases, reported briefly from my notes, may not prove uninteresting, as the treatment includes the use of both of the remedies which are so highly spoken of. Although I had occasion to treat some thirty-five cases of erysipelas this summer, most of them were of the cellulito-cutaneous and cellular varieties, which demanded free and numerous incisions, and in which the depending upon milder measures would have led to disastrous results. Several of the cases, however, were of the cutaneous variety, and among these two seemed to present an opportunity for the fair trial of carbonate of lead. One of the two receiving also injections of resorcin.

CASE I.—Alice B—, aged thirty, who had been operated upon a week previously for the removal of enlarged lymphatic glands of the neck, was sent to the erysipelas ward on May 16, 1883, with a cutaneous erysipelas, which included the right ear, and which had extended anteriorly half way across the cheek, and posteriorly to the back of the neck; involving the integument as far down as the vertebra prominens. Blebs and vesicles had appeared only upon the helix of the ear when the disease had first manifested itself two days previously. The record of the vital signs is not of sufficient significance to be reported here. White lead paint, which I had carefully prepared myself with linseed oil, was spread thickly over the involved portions of the skin, and at the same time the following internal treatment was commenced: Tincture of the chloride of iron in half-drachm doses, well diluted with whiskey and with one-fourth of a grain of morphine added, every three hours. Five-grain doses of sulphate of quinine every three hours, and each dose to be given in the interval between

two doses of the iron. Rochelle salt in sufficient quantity to keep the bowels open. It may be well to mention that the paint, after being applied, was covered with gutta-percha tissue for neatness sake.

May 17th.—Erysipelas showing no tendency to further extension. Pain very much less than yesterday.

May 18th.—Erysipelas limited. Little pain. Internal treatment stopped.

May 19th.—Erysipelas extending rapidly along the cheek, and upward on the scalp. Temperature elevated in the morning, but reduced promptly by sponge-baths and quinine. White paint applied to beyond margins of diseased area.

May 20th.—Erysipelas extending more slowly. Lead paint removed and internal treatment recommenced.

May 21st.—Erysipelas leaving the parts first attacked, but extending down the front and sides of the neck. Fomentations of hot lead and opium wash, and carbolic acid solution (1—40) in equal parts are employed locally.

May 22d.—Erysipelas decreasing at all points.

May 23d.—Improving with great rapidity.

May 28th.—Discharged cured.

CASE II.—Ann McC—, aged fifty-eight. Brought to the hospital on May 25, 1883, suffering from idiopathic cutaneous erysipelas. The patient is not rational and cannot give a reliable history.

The skin over the entire face, with the exception of the chin, is very much swollen, and hyperæmic. The ears are involved. Blebs and vesicles cover all of the diseased surface. Much constitutional disturbance exists. No local treatment is resorted to at first. The intended internal treatment is substantially the same as in case No. 1. As patient has passed no urine for five or six hours after entering the hospital a catheter is inserted into the bladder, and an ounce and a half of turbid urine drawn. This urine is found to contain about fifty per cent. by volume of albumen, and a few granular casts.

The patient is now to take one drachm of bitartrate of potassium well diluted, and half an ounce of infusion of digitalis every four hours. And in case of a rebellious stomach poultices over the kidneys are to be substituted for the above.

May 26th.—Vital signs nearly normal. The erysipelas appears to be stationary. Less than three ounces of urine having been passed in the last twenty-four hours, dry cups are applied over the kidneys for fifteen minutes. Patient again cupped six hours later.

May 27th.—Vital signs normal, erysipelas stationary. Yesterday's cupping has been partially successful, as twenty-four ounces of urine have been passed in twenty-six hours. This urine, however, contains about sixty per cent. by volume of albumen, and is loaded with granular, epithelial, and hyaline casts. Blood is also present.

May 28th.—Erysipelas extending rapidly down the back of the neck. Vital signs normal. Urine in nearly normal amount since last note. The scalp, which is now œdematous, and the back of the neck, are enveloped in moist oakum, covered with oiled silk.

June 1st.—The erysipelas has rapidly departed from the face, but is travelling down the back with greater speed. The affected portions of skin to the left of the spinal column are painted over with tincture of iodine, and on the right side hypodermic injections of a five per cent. solution of resorcin are made into the subcutaneous connective tissues, in the hope of destroying the micrococci which fill the lymphatics in the advancing line of the disease. The injections, of two minims each, are made about a quarter of an inch apart, half an inch or more ahead of the whole advancing line on the right side of the spinal column, between the eighth dorsal vertebra and the right shoulder. There is now almost no urine excreted by the kidneys.

June 2d.—The erysipelas has continued straight on down the back without any check whatever from the local treatment. The affected portion of skin to the

right of the spinal column is covered with collodion, and a thick layer of white lead paint is spread upon the corresponding left side. Patient very stupid. Almost no urine.

June 3d.—The erysipelas has extended about two inches lower on each side of the spinal column, and is creeping toward the sides of the chest. All of the more recently diseased surface is washed with a saturated solution of sulphate of iron in the morning, and as the disease is still progressing at evening, collodion is substituted. There is probably as much reason in trying to control the local lesion as there would be in endeavoring to stop the eruption of scarlet fever by the use of the same remedies.

June 4th.—Patient dies quietly at 3 A.M. The result of the autopsy in this case was extremely interesting, but as it had no particular bearing upon the efficacy of white lead paint, or of resorcin, in controlling erysipelas, I will omit the description of it.

ROBERT T. MORRIS, M.D.

BELLEVUE HOSPITAL, NEW YORK CITY.

Army News.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from September 15 to September 22, 1883.

CAMPBELL, JOHN, Lieutenant-Colonel and Surgeon, Medical Director, Department of the South. Granted leave of absence for fifteen days. S. O. 94, par. 2, Department of the South, September 13, 1883.

ALEXANDER, CHARLES T., Major and Surgeon. On being relieved from duty at the United States Military Academy, October 1, 1883, to report in person to the Commanding General, Department of the Missouri, for assignment to duty. S. O. 211, par. 7, A. G. O., September 14, 1883.

ALEXANDER, CHARLES T., Major and Surgeon. Granted leave of absence for four months, from October 1, 1883. S. O. 213, par. 1, A. G. O., September 17, 1883.

GIBSON, JOSEPH R., Major and Surgeon. Relieved from duty in the Department of the East, October 1, 1883, and to report by letter to the Commanding General, Department of the South, for assignment to duty. S. O. 211, par. 7, A. G. O., September 14, 1883.

HORTON, SAMUEL M., Major and Surgeon. Relieved from duty in the Department of the Platte, October 1, 1883, and to report in person to the Commanding General, Department of the Missouri, for assignment to duty. S. O. 211, par. 7, A. G. O., September 14, 1883.

MEACHAM, FRANK, Major and Surgeon. Relieved from duty in the Department of the East, October 1, 1883, and to report in person to the Commanding General, Department of the Platte, for assignment to duty. S. O. 211, par. 7, A. G. O., September 14, 1883.

SMITH, ANDREW K., Major and Surgeon. Relieved from duty at Willett's Point, N. Y., October 1, 1883, and assigned to duty at U. S. Military Academy, West Point, N. Y. S. O. 211, par. 7, A. G. O., September 14, 1883.

TAYLOR, MORSE K., Major and Surgeon. Relieved from duty in the Department of the East, October 1, 1883, and to report in person to the Commanding General, Department of the Missouri, for assignment to duty. S. O. 211, par. 7, A. G. O., September 14, 1883.

WOLVERTON, WILLIAM D., Major and Surgeon. Relieved from duty in the Department of Dakota, October 1, 1883, and to report in person to the Commanding General, Department of the East, for assignment to duty. S. O. 211, par. 7, A. G. O., September 14, 1883.

APPEL, DANIEL M., Captain and Assistant Surgeon. Relieved from duty in the Department of the Missouri, October 1, 1883, and to report in person to the Commanding General, Department of the East, for assignment to duty. S. O. 211, par. 7, A. G. O., September 14, 1883.

MERRILL, JAMES C., Captain and Assistant Surgeon. Relieved from duty in the Department of Dakota, October 1, 1883, and to report in person to the Commanding General, Department of the East, for assignment to duty. S. O. 211, par. 7, A. G. O., September 14, 1883.

MUNN, CURTIS E., Captain and Assistant Surgeon. Relieved from duty in the Department of the Missouri, October 1, 1883, and to report in person to the Commanding General, Department of the East, for assignment to duty. S. O. 211, par. 7, A. G. O., September 14, 1883.

MAUS, LOUIS M., Captain and Assistant Surgeon. Relieved from duty in the Department of the Missouri, October 1, 1883, and to report in person to the Commanding General, Department of Dakota, for assignment to duty. S. O. 211, par. 7, A. G. O., September 14, 1883.

PATZKI, JULIUS H., Captain and Assistant Surgeon. Relieved from duty in the Department of the South, October 1, 1883, and to report in person to the Commanding General, Department of the East, for assignment to duty. S. O. 211, par. 7, A. G. O., September 14, 1883.

PRICE, CURTIS E., Captain and Assistant Surgeon. Relieved from duty in the Department of the East, October 1, 1883, and to report in person to the Commanding General, Department of Dakota, for assignment to duty. S. O. 211, par. 7, A. G. O., September 14, 1883.

VICKERY, RICHARD S., Captain and Assistant Surgeon. Relieved from duty in the Department of the Platte, October 1, 1883, and to report in person to the Commanding General, Department of the Columbia, for assignment to duty. S. O. 211, par. 7, A. G. O., September 14, 1883.

WEISEL, DANIEL, Captain and Assistant Surgeon. Relieved from duty in the Department of the East, October 1, 1883, and to report in person to the Commanding General, Department of the Platte, for assignment to duty. S. O. 211, par. 7, A. G. O., September 14, 1883.

APPEL, AARON H., First Lieutenant and Assistant Surgeon. The leave of absence granted July 20, 1883, extended one month. S. O. 211, par. 10, A. G. O., September 14, 1883.

BREWSTER, WILLIAM B., First Lieutenant and Assistant Surgeon. Granted leave of absence for two months, from October 1, 1883, with permission to apply for an extension of four months. S. O. 107, par. 1, Military Division of the Missouri, September 15, 1883.

STRONG, NORTON, First Lieutenant and Assistant Surgeon. Now on duty in the field near Fort Thornburgh, Utah, to accompany command to Fort Douglas, Utah, and there await further orders. S. O. 101, par. 2, Department of the Platte, September 17, 1883.

SALICYLATE OF SODA IN PHLEGMASIA ALBA DOLENS. —Dr. Vigar has met with success in the treatment of several cases of milk leg by salicylate of soda. He gives it in doses of one drachm per diem. He states that in all the cases in which he has tried the remedy the patients were able to leave their beds in less than three weeks, and all recovered perfectly without any cedema or nodosities on the leg.—*El Siglo Médico*.

Medical Items.

CONTAGIOUS DISEASES.—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending September 25, 1883 :

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.

September 18, 1883. . . .	0	69	38	3	22	19	0	0
September 25, 1883. . . .	0	84	29	7	4	17	0	0
<i>Deaths.</i>								
September 18, 1883. . . .	0	13	14	3	2	14	0	0
September 25, 1883. . . .	0	12	2	5	2	12	0	0

REMOVAL OF KIDNEY AND GALL-BLADDER.—Dr. Langenbeck, at the recent meeting of the German Surgical Congress, showed a woman, aged thirty-four, from whom he had removed the gall-bladder successfully. Two years before she had had a floating kidney removed.

TREATMENT OF SIMPLE CHANCRE BY HEAT.—A member from Lyons read a communication before the Académie de Médecine on the treatment of simple chancre by heat. As the results of his experiments he was led to consider that the employment of an elevated temperature was an excellent means of annihilating the virus. The author recommended that a hip-bath should be given between 104° and 107°, and borne for several hours. He believed that this treatment would suffice to destroy the virus in twenty-four hours. In any case it was certainly the best treatment of phagedanism and those chancres complicated with phimosis that no dressing can attain. It is needless to add that the doctrine of M. Pasteur as to the cause of virulent diseases has suggested this treatment.—*Medical Press and Circular*.

INCISED WOUND OF THE KNEE-JOINT; PYARTHROSIS; ULCERATION OF THE ARTICULAR CARTILAGES; RECOVERY IN FIVE MONTHS.—Dr. R. C. Van Wyck, of Hopewell Junction, N. Y., sends us a carefully written history of a case of the above kind. The patient was a delicate, scrofulous boy, eleven and a half years of age. He accidentally received a deep transverse cut just above the left patella from the fall of an axe. The wound opened the knee-joint, but it was not attended to for over a week. Consequently suppuration set in, the opening healed, but the pus burrowed. A large abscess formed about the joint and finally penetrated it. Incisions had to be made on both sides of the joint and into the popliteal space in order to secure free drainage. Bed-sores developed, and the patient was reduced almost to a moribund condition. By free drainage, thorough cleansing of the wound, and proper diet, the patient began to improve. Dr. Van Wyck ascribes the favorable turn in the disease to the use of syrup of hypophosphites. As the boy convalesced a modified Stillman's splint was applied.

THE ETHER DOUCHE OR LAVEMENT FOR THE RELIEF OF PAIN.—Dr. C. H. Hughes speaks favorably of the use of lavements of ether for the relief of headaches and neuralgias.—*Medical Times*.

THE OATH WHICH THE GERMAN MIDWIFE IS OBLIGED TO TAKE is as follows: "I swear by the Almighty and Allknowing God, that I will practise the midwife's art to the best of my skill and ability, helping rich and poor with equal readiness. I will conduct myself as a true and conscientious midwife. So help me God!"

CHANGES IN THE STRENGTH OF SOME OF THE OFFICIAL PREPARATIONS IN THE NEW PHARMACOPŒIA.—The *Virginia Medical Monthly*, hearing that Dr. Squibb declines to follow the directions of the new Pharmacopœia regarding the strength of certain preparations, reads that gentleman a lecture. It says that "it looks over-officious in him to confront national opinion, confuse both doctor and druggist, and risk, perhaps, human life by obstinacy. By such a course as he is pursuing in this matter, he will do others injury, and himself no good. He will confuse everybody. If Dr. Squibb is the authority, let us authoritatively know it, as a profession; if the United States Pharmacopœia is the authority, let us be in accord on the subject where absolute harmony is essential. Because of such statements as he is making, or has published, and because of the action of local pharmaceutical societies throughout the country, we may do some good by suggesting to each doctor to ask his druggist whether he is following the revised U. S. Pharmacopœia or Dr. Squibb."

A HINT FOR NEW YORK CITY AUTHORITIES.—The municipal authorities of Berlin have adopted regulations forbidding the erection of houses over seventy-nine feet in height and having more than five lodging floors; at present they are built with seven or eight stories.

THE SURGERY OF VIENNA differs widely from that of America. There is not nearly so much acute surgery, if I may be allowed the expression; that is, fractures, dislocations, and general mash-ups are not common, due partly to the fact that the railroads are better managed than with us, the staging and scaffolding around buildings much more securely erected, the buildings themselves more substantially built, and partly, perhaps, to the fact that the people themselves are naturally cautious, and that as they are punished for being run over, they take pains to keep out of the way of vehicles. Tumors of all kinds, carious and tuberculous processes of the bones, deformities, joint diseases, and hernia, are very common.—*Cor. Maryland Med. Jour.*

TO DETECT ADULTERATIONS IN OLIVE OIL.—According to the *Moniteur de la Pharmacie* cotton-seed oil, when used as an adulteration or substitute for olive oil, may be detected by the following test: Put one part by weight of the oil to be tested in a test tube with two parts of pure colorless nitric acid, shake thoroughly for thirty seconds, and then let the test tube stand for five or six minutes. At the end of this time the oil will rise above the acid. If the olive oil is unadulterated it will be of a light gray color with a yellowish tinge, but cotton-seed oil will assume a dark brown, almost black, coffee color. Varying shades from a golden yellow to brown, according to the proportions of the admixture, will be produced in adulterated oil. By this method it is possible to detect the presence of five per cent. of cotton-seed oil.

THE RAPID INCREASE IN THE POPULATION OF CHICAGO.—In a paper read before the Chicago Medical Society and published in the *Medical Journal and Examiner* for September, 1883, Dr. Henry Ogdon reports the birth of five sets of triplets in that city within a period of five months. Not content with that, he supplements his paper with a report of two other cases of triplets born in the vicinity.

A PRACTICAL MEDICAL EXAMINATION.—The *London Medical News* relates an instance in which a candidate was treated with unusual consideration by his examiners. Requested by one of the latter to cut down on and tie the subclavian artery, the candidate did as directed, but could not at once find the vessel. Irritated, seemingly, by his failure, the examiner urged him to "Pick it up, sir; there it is, right under your nose," and on the candidate mildly suggesting that this particular structure was a cord of the brachial plexus, the second examiner present lifted it and divided a nerve. Examiner No. 1 then

at once repudiated having called this the artery, which, he affirmed, was another adjacent structure. Proceeding, therefore, to raise it and cut it through, he exhibited it in commencing triumph, which quickly collapsed as another nerve appeared in section. The candidate was passed.

HOW TO KEEP THE HYPODERMIC SYRINGE IN ORDER.—Dr. William H. Morse, of this city, describes the following method of keeping the hypodermic syringe in order. It is, he says, "the very best," the syringe being always ready and in good order even if it has not been used for months. The method, besides being simple, is inexpensive: "Unscrew the bowl of your syringe, take out the piston-rod, unscrew the *lower* piston leather and take it off, then put in its place a small piece of chamois skin, and replace the leather and screw it tight. Now trim the chamois to the size of the bowl, and replace the piston, and the work is done. You will observe that you have only placed a bit of chamois *between* the *two* piston leathers. You now have a syringe which is in working order the *moment* water is introduced."

A CURIOUS VERDICT IN REGARD TO AN INJURY OF THE EYE.—In a recent case in a Pennsylvania court a large verdict was obtained for an injury to the eye, which had apparently healed, but which might possibly become serious. The judge said "the cornea of the plaintiff's eye was cut in three places, and the iris became attached to the lower branches of the corneal injury. The power of the eye was permanently weakened, but its condition has remained unchanged for the last twenty months, while subjected to the severest tests, and during this time the plaintiff was able to work from eleven o'clock P.M. till seven o'clock A.M." Under these circumstances the Court held that a large verdict based upon a possible subsequent inflammation was excessive, and directed that a new trial should be had, where the actual and not the possible damage should be considered.

THE ORIGIN OF MALARIA.—Dr. Daniel Parker, of Calvert, Texas, sends us a communication in which he protests against the views recently enunciated by Dr. Charles P. Russel in *THE RECORD*, in an article on "The Change of Medical Opinion in regard to the Cause and Recent Extension of Malaria." He thinks that there are very few careful observers who will agree with the statement of Dr. Chadbourne, there quoted, that he "adhered to no opinion whatever, based upon sufficient facts to make it valuable, as to how malaria arises." Dr. Parker says: "The statement that malarial disease occurs where vegetable decomposition is, to any great extent, impossible, may be answered by saying that such places are probably influenced in this respect by atmospheric currents, water supply, or some at present unknown conditions, and that a thorough investigation of each locality in the light of its peculiar surroundings would be about as likely to prove as to disprove the time-honored theory. The counter-statement that 'very many more instances' exist 'where all the so-called conditions for the production of malaria have always been present without such poison having manifested itself,' may be reconciled by supposing that some factor, in addition to the simultaneous operation of air, heat, and moisture causing vegetable decomposition, is necessary for the production of malaria, or that in such localities certain conditions, with which we are at present unacquainted, exist prejudicial to the existence or activity of malarial poison. Neither of these explanations invalidates the accepted theory. If called on for facts in support of the theory in question, I should hardly know where to commence. The literature and experience of the profession teem with them. To say that exposure of the unacclimated to paludal emanations at certain seasons of the year, in certain localities, is followed by malarial disease, would convey much the same idea to any one of experience in such matters, as to say

that exposure of the unprotected to yellow fever atmosphere is followed by yellow fever. The relation of cause to effect is not more marked in one instance than in the other. This is not a revelation of scientific or professional research, but a matter of common observation. A large majority of the intelligent laymen in malarial districts can predict with a near approach to certainty whether a given locality will be healthful or otherwise, and they will all base their prediction on the exposure or non-exposure of the particular locality to emanations arising from vegetable decomposition, as determined by proximity to swamps or alluvial lands, and influenced by atmospheric currents, elevation, etc. To say that no such thing as a malarial germ exists, because no one has seen such an object, is simply to say that in this direction research has attained its utmost limits, and that there is nothing more to be learned. This is cutting off investigation precisely where we have reason to hope for the grandest discoveries, and needs only to be mentioned to show how entirely it is opposed by the experience of the profession, and by the spirit of progress which animates such workers as Pasteur, Koch, Belfield, and others."

THE RELIEF OF CRAMPS.—A correspondent of the *British Medical Journal* suggests for the drug-treatment of painful cramps the following, subject to the peculiarities of the patient: Ext. hyoscyami, gr. iij.; camphoræ, gr. ij.; morphinæ bromidi, gr. $\frac{1}{12}$, in a pill at bedtime. This pill has succeeded perfectly in a recent case. Another correspondent suggests small doses of bichloride of soda.

ARSENIC AS A PROPHYLACTIC AGAINST MALARIA.—Experiments have been carried out in Italy, under the direction of Tommasi-Crudeli, to ascertain the prophylactic value of arsenic against malaria. The results have, says a correspondent of the *British Medical Journal*, been quite favorable. The number of persons placed under arsenic was 455; 401 men and 54 women. Of these, 250 were victims of chronic malarial poisoning, 115 had been recently infected, and 90 were in fair health. There were cured, or, if well, there remained free from attacks, 338; 43 were not benefited; and in 74 the result was doubtful. He particularly notes that of the 90 who never had had any malarial fever, only nineteen per cent. were attacked in this unhealthy year, and those attacked only had slight fevers readily yielding to quinine. The treatment was begun with one lamel containing two milligrammes, about the one thirty-fifth of a grain, of arsenious acid daily. After four days, a second lamel was given, and so on, until four were taken each day. In a few cases, the dose was increased to seven lamels, about one-fifth of a grain, daily, and apparently with better results.

PHILADELPHIA DIPLOMAS IN AUSTRALIA.—The Rev. R. V. Danne, of Melbourne, stated that he desired to become a missionary, and attended a few lectures off and on at the Melbourne Medical School. He then sailed for America, and returned in nine months armed with a diploma from the Medico-Chirurgical College in Philadelphia. On the strength of this he sought registration as a regular physician, but was rejected. The diploma was said to have been a gem, and couched in the most wonderful Latin.

A WELL-MEANT ENDEAVOR TO RELIEVE SUFFERING.—A Chicago correspondent of the *Atlanta Medical Register* relates the following incident: "A physician living on the South Side was recently called in to catheterize the bladder of a man said to be dying from kidney disease and suffering from retention. On his arrival he found the patient comatose, and in the care of two female physicians of the homeopathic persuasion, one of whom had been vainly endeavoring to reach the bladder with a female catheter, which she tendered him on his arrival, alleging as the cause of her failure that she was

not accustomed to catheterize the male bladder. Saying that he had an instrument of his own which he was used to, he drew off twenty-four fluid ounces, and retired with a firm conviction that this was one of those events which make one smile even in the presence of death."

A NEW FORM OF ASPIRATOR.—An aspirator has recently been devised by M. Creuzan, of Bordeaux, which is worked without piston or stop-cocks. It consists essentially of a large caoutchouc bulb, which, by means of a special arrangement of valves, may serve as an aspirator or an injector. A glass cylinder is attached to the bulb, so that the nature of the fluid may be readily determined. There is no possibility of air entering the cavity from which the fluid is to be removed, and the instrument possesses the further advantage that the operator requires no assistant, but can readily hold the trochar in position with one hand and the aspirator with the other. Any quantity of fluid may be removed by simply compressing the bulb without detaching the instrument from the needle.

AN ADVANCE IN OPHTHALMOLOGY.—In a recent case of vitriol-throwing in France the victim, M. de la Roche, suffered a total loss of eyesight. But a morning journal of Paris gravely states that the medical attendants have succeeded in replacing his burned organs by the eyes of a rabbit and that he now sees perfectly.

HOW TO KEEP THE HYPODERMIC SYRINGE IN ORDER.—Dr. W. B. M——, of Vernalia, La., advises the substitution of "green-packing," such as engineers use, for the old piston leather in the syringe. The instrument can then be neglected for some time and yet be ready for use. A "Subscriber," from Chicago, writes that by getting one of Fowler's hard-rubber syringes, with hard-rubber pistons, no trouble is ever experienced.

IODOFORM AND ERYSIPELAS.—Dr. C. G. Roehr, of Ledyard, Wis., writes in reference to a statement by Dr. Seely, of Cincinnati, that iodoform caused erysipelas, as follows: "I think some two years since I saw in some German journal that, owing to the great increase in erysipelas, iodoform had to be given up in surgical dressing. I have seen antiseptics, including iodoform, tried thoroughly, and have seen a number of the so-called cases of erysipelas, and found them to be simply cases of erythema or dermatitis venenata. By experimenting I have found that it can be cured by quitting the use of the iodoform. I have caused and cured it in this way a number of times on the same patient—and it occurs in possibly one per cent. of all surgical cases. This is what our professors call idiosyncrasy, and we have the same result in the use of arnica and a number of other drugs."

TREATMENT OF THE OPIUM HABIT.—Dr. A. W. Jackson, of Wurtsboro, N. Y., writes us that he has been quite successful in treating cases of the opium habit by applying the following measures: First, cheerful surroundings, and plain, wholesome, assimilable food. Second, unceasing watchfulness on the part of the friends and attendants of the patient. Before the treatment is commenced, the patient should be put in as good a condition, physically, as possible. In an old case, commence the treatment by cutting off two-thirds of his daily supply of morphine. If he had been taking twelve grains per day, prepare the following prescription:

R. Morphine sulphatis..... grs. lvi.
Ext. belladonnæ solid grs. xij.
Quinine sulphatis..... grs. xxxv.
Capsici pulv..... grs. iij.
Ft. in mass et in pilul. No. 42 div.
S.—One pill ter in die.

Also give about eight to twelve drops conc. tr. avenæ sativæ in a wineglass of warm water ter in die. Also a glass or two of old ale during the twenty-four hours.

Milk punch can be given also, as the appetite will be found very difficult to manage. The supply of pills being calculated to last for two weeks, it becomes necessary to renew them at that interval. At each renewal cut off a given amount of the morphine until the pills contain only the belladonna, quinine, and capsicum. Continue with them for a month or less, and it will be found that they can then be dispensed with, and any good tonic substituted. The faradic current may be used also with advantage.

AMERICAN CATARRH.—Dr. Morell Mackenzie gives this name to a naso-pharyngeal catarrh which he found so prevalent in this country, that he calls it "a national complaint." He ascribes it to the universal prevalence of *dust*, in city and country. We do have plenty of dust everywhere, but less in winter than summer, while the "American catarrh" is far more frequent and obtrusive in the winter. Therefore, we fear that Dr. Mackenzie is too narrow in his etiological theory. The following is the doctor's somewhat highly colored description of the too atmospheric distribution of American soil: "Owing to the immense size of the country, and its sparse rural population, the country roads have not, as a rule, been properly made, and except in some of the older States, are merely the original prairie tracks. In the cities, notwithstanding the magnificence of the public buildings, the splendor of many of the private houses, and the beauty of the parks, the pavement is generally worse than it is in the most neglected cities of Europe; such indeed as are only to be found in Spain or Turkey. It must be recollected also that, whilst in the decayed towns of the Old World there is very little movement, in the American cities there is a ceaseless activity and an abundance of traffic. Hence the dust is set in motion in the one case, but not in the other. The character of the dust, of course, varies greatly according to the locality. In some parts, it is a fine sand; in others an alkaline powder; whilst in the cities it is made up of every conceivable abomination, among which, however, decomposing animal and vegetable matters are not the least irritating elements. An idea may, perhaps, be formed of the state of the atmosphere from a consideration of the fact that in many cities the functions of the scavenger are quite unknown."

THE TREATMENT OF CRAMP.—Surgeon Robert Mann writes in the *British Medical Journal*: "There is no remedy I have found to answer, except the raising the head of the bed. I cause two bricks to be placed under each leg, or a block of wood of the same thickness as two bricks. Patients who have suffered at night, crying loudly with pain, have found the above plan an immediate, certain, and permanent relief."

BORACIC ACID.—Dr. Squibb writes of boracic or, more properly, according to the nomenclature of the late Pharmacopœia, *boric acid*, as follows: "If the powder be needed, as is generally the case, it should be specified in the prescription. The powder should be very fine, and should be white and light, and entirely free from particles when rubbed between the finger and thumb, feeling very like powdered soap. It is only such powder that answers well in eye surgery or general surgery for dressings, and solutions are also best made from it. A saturated solution contains about nineteen grains to the ounce, and from ten grains in the ounce to saturation it is used as an eye-wash or to granulating and suppurating surfaces. It is a very bland and soothing application, both in powder and solution, relieving irritation and arresting suppuration. It is a potent antiseptic, much less expensive than salicylic acid, and it is odorless and more easily managed than carbolic acid. It is probably better than either to preserve hypodermatic solutions. In surgical dressings it has the great advantage over carbolic acid of not being irritant nor poisonous. But not being volatile it does not deodorize the air."—*Epiphenis*.

METHODS OF MEDICAL INSTRUCTION.

INTRODUCTORY ADDRESS DELIVERED TO THE STUDENTS
OF THE MEDICAL DEPARTMENT OF THE UNIVERSITY
OF THE CITY OF NEW YORK, OCTOBER 2, 1883.

By HERMAN KNAPP, M.D.,

PROFESSOR OF OPHTHALMOLOGY; SURGEON OF THE N. Y. OPHTHALMIC AND AURAL
INSTITUTE; LATE PROFESSOR AT THE UNIVERSITY OF HEIDELBERG.

GENTLEMEN: Which is the best method of medical instruction? Evidently that by which the student learns most. So long as students differ in aptitude to learn, owing to differences in mental capacity, attentiveness, energy, perseverance, preliminary attainments, and in bodily health and strength, fitting them for more or less prolonged labor—so long as such and other differences exist among the students, one and the same method cannot be the best for all. For the *student* it is of the greatest importance to select that school and follow that method which is best adapted to his individual qualification; whereas the *school* has to consider the character of the students who make up its classes. If there is more or less homogeneity among the students the course of instruction can be correspondingly uniform, but if there is great diversity the means and modes of instruction must be so numerous and varied as to furnish suitable opportunities for all.

Now, if there must be a mutual adaptation of student and college, the one will require of the other certain qualifications without which a working together for a given purpose is impossible. The student must possess a certain stock of general knowledge, and the college must command, first, a sufficient corps of well-qualified teachers, and secondly, a collection of auxiliary means and material of instruction, large and varied enough to meet the legitimate demands of every student. Among these means of instruction I will mention spacious rooms and abundant material for dissecting; an anatomical museum; chemical, physical, physiological, microscopical, pharmacological, and pathological laboratories; dispensaries; hospitals; autopsy rooms; and last, but not least, a large and well-appointed college building, which encloses a part of the mentioned institutions, and which is located at a convenient distance from the others, for instance, the hospitals, so as to make it the centre, the starting- and rallying-point—in short, the home of the student.

If we examine the manner in which medicine, at the present day, is taught in different countries we can distinguish two systems, which may be termed the European and the American.

It is quite remarkable that each system, with national subdivisions, bears the stamp of the political development of its country.

The European method is planned, regulated, supported, and controlled by the political government. The State allows nobody to enter upon the study of medicine unless he has had a collegiate education carried on under an official programme. When the student presents himself at the medical school for matriculation he must have his certificate of maturity in hand. Then he has to go through a systematic course of professional study for at least four years, after which he must pass a final examination before

a State board, and receives his license from the State authorities. The degree of M.D. is an academic honor, which in some countries is obligatory, in others optional. The medical schools, with all their appurtenances, are State institutions. The professors are appointed and salaried by Government, and are held responsible for the efficient teaching of all the departments of medical science and art in which the candidates for the license of practice are examined. The different schools of one or several countries, for instance all the universities of the German Empire and of the German-speaking provinces of Austria, Russia, and Switzerland, are brought up to the same standard. The student is at liberty to begin and complete his curriculum at one school, or to change as often as he pleases, only not during the course of a term. He can select also at his option that State board before which he desires to pass his fractional or entire examination. His license entitles him to practise in any part of the country. Of late, international agreements permit licentiates of medicine of one country to practise in another, subject to the laws of that country.

The *American method* of medical instruction differs widely from the European. It is the child of the free institutions of the country, letting everybody make of himself what he can, restricting his ambition by no barriers, asking few or no preliminary questions. The American medical students come from different stages of society and culture, one from the plough, another from college. Some of our colleges are inferior, others equal, and others—for instance, Harvard and Yale—superior to the German “gymnasium.” He presents himself at the medical school, saying: “I am willing to work, to work hard. Will you take me as I am?” The schools, with a few exceptions, answer cheerfully: “You are welcome.”

The young man matriculates and receives a little card, the programme of lectures and clinics, which informs him that eight or nine hours of instruction are provided for him every day. He goes to work with a will. During the first weeks he attends all of them, but when the interest of novelty and the enthusiasm for a high cause are gradually toned down by the hard daily labor, he chops off a goodly number of branches from the luxuriant programme. Next year, and perhaps the year after, he comes again and fills in what before he had left out. After three years' study under the guidance of a regular physician and after the attendance of at least two regular courses of lectures at a recognized college, each course of no less than twenty weeks' duration, he has to pass an examination in seven branches: anatomy, physiology, chemistry, materia medica, obstetrics, surgery, and medicine, before the seven professors, constituting the regular faculty of the school. If he passes this examination to the satisfaction of said professors he receives from them the degree of M.D., which lawfully licenses him to practise all the departments, general and special, at any place in the United States. Most of the Canadian medical colleges, as far as I can learn from their announcement catalogues, are arranged on the same plan. This plan was in operation in England for a long time, until the “Medical Act” in 1858 abolished it. Since that time the English medical student is no longer apprenticed to a practitioner, but has to undergo a preliminary examination in the classics, mathematics, history, and French, has to be at the medical school four full years, and is finally examined and licensed by one of the boards authorized by government.

Let me now sum up the characteristic features of the two systems :

1. *The European.*—A liberal preliminary education ; four years of professional study ; examination and license by a board authorized by government.

2. *The American.*—Requirements of preliminary education very modest or waived altogether ; a three years' tutelage under a practitioner ; during that time the attendance of two regular courses, each no less than twenty weeks, at a recognized medical school ; the one-class lecture system (*i.e.*, no graded instruction, but the second course a repetition of the first), a written examination in seven topics ; approbation and license by the seven professors constituting, as a chartered private corporation, the regular faculty.

If I have presented the two systems correctly and am asked which is the higher, I unreservedly declare myself for the European, and doubt whether there is any one in this assembly who would differ from me ; at least I am sure that I speak the mind of every one of the teachers at the University of the City of New York. But, gentlemen, we are not responsible for the existence of the American system, we have not made it ; it is, as I said before, the child of the free institutions of this country. The European system is the higher, is the higher still, and toward it we are tending. Will it always be so? No, most positively no! If the American method of medical instruction is the outgrowth of the American political constitution, it must grow and develop with it. The American constitution is the highest that has ever been framed, so sublime that it will take centuries yet for the people to become worthy of it. By giving every man equal rights of opinion, speech, and action, it takes away all barriers of individual development from the lowest position to the highest. I am not digressing from my subject, for the scientific progress of a nation depends in a great measure on its political condition. The science of man, anatomy and physiology, is the highest of all the sciences, and its application to the art of healing puts on it a divine crown. England had a free constitution before any of the modern European nations. In the last century it brought forth men like Harvey, Jenner, Abernethy, Astley Cooper, John Hunter, Thomas Young, and many others, whose names are registered in the history of civilization as benefactors of mankind for all time to come. They began to collect facts, founded hospitals, museums, and libraries whose treasures are still today inexhaustible sources of information for the most erudite scientist as for the tyro. These men learned and taught what they knew in schools conducted exactly like our own.

Then came the emancipation of Gallic thought at the time of the great revolution in 1792, and the French became the leading nation in politics, taste, art, and science until 1870. When I began my medical studies, in 1851, the text-books recommended at the German universities were prevalently translations from the French, and every one of us who aimed at a higher than an average position in life thought it incumbent upon himself to study, after his examination, at least six months in France, which meant Paris. When, fifteen years later, I visited again the medical school of that magnificent city I found that the text-books in the hands of the French students were to a great extent translations from the German, while in Germany the translations from the French had almost disappeared. The great French physicians, Bichat, Laennec, Magendie, Louis, Dupuytren, Nélaton, and many others, had disappeared and had not been replaced by men of equal eminence. Schools and collections had been neglected. The glittering third empire, despotic and hypocritical, erected on the horrible crime of the 2d of December, 1851, had laid, it seemed, iron fetters on the minds of one of the most gifted nations that the earth has ever produced.

German thought imperceptibly took the ascendancy in directing the march of European culture. To what

strength the despised and ridiculed German people had unostentatiously grown up was demonstrated by the crisis of 1870, when the gigantic but hollow balloon of French glory burst like a soap-bubble before the breath of the German army. The German successes, gentlemen, were not obtained by the chance of the moment—great events never are, they are the result of slow growth and long preparation. Shall I tell the younger members of my audience what was the origin of this astonishing rise of the German nation? It is expressed by a few words which King Frederick William III. of Prussia spoke in his inaugural address at the foundation of the university of Berlin in 1817: "We have," said the king mournfully, "been humiliated and depressed in every respect, our country is ransacked and impoverished, our population reduced to nine millions. We must try to gain what we have lost in material strength by the development of mental power." And as the university of Berlin—which to-day is, perhaps, the most active centre of scientific movement—was founded in a truly national spirit, so schools of all kinds and degrees sprang up throughout Germany by the hundreds and thousands. You all have heard the proverbial sentence which, in 1871, was echoed from one end of the globe to the other, that the Franco-Prussian war was decided by the German schoolmaster. Many of the men who have rendered the German medical school famous are still living. I therefore refrain from mentioning their names. Any one who has not been in Europe for ten years will be astonished at the immense progress observable in the medical departments of the German universities. The completeness and magnificence of the institutions surpass all expectation. Anatomy, physiology, chemistry, physics, the branches of natural history and pathology, the different departments of medicine, even the so-called specialties, have all their separate institutions, the smallest of which can compare in size with the average American college. On inquiring what was the cause of this recent rapid development, I learned that by the governments of the different States one-half of the money received from the French as war indemnity, had been used for military purposes, the other half for the universities. You see they are still true to the traditions of the old King of Prussia.

When will America come to take the lead in medical affairs? Will she ever? Gentlemen, I am convinced that so much as the European civilization is above the Asiatic, so much will the American outrank the European. The Asiatic castes hindered the development of individual talent, and the European society, with its odious distinctions of common people, gentry, nobility, and royalty, is only a faint photograph of its Asiatic prototype. An immense soldiery is used as much for the perpetuation of aristocratic prerogatives as for national defence. In our, my adopted, country each man can elevate himself as high as his physical and mental means will permit, no classes privileged by birth stand in his way, and, besides, he has elbow space enough to spread in every direction. If Europe has the advantage of an old culture, of museums, libraries, collections of art, and all kinds of scientific institutions, America gives her sons one advantage worth more than all the European treasures: *an unbounded opportunity*. To all of you, gentlemen, she offers a successful career.

Although I have unhesitatingly said before that the European system of medical education shows a higher standard than the American, I am sure that an American medical college is better suited to your requirements than a European. The European system is not all perfection ; it has its disadvantages as well as the American, and it behooves me to point them out so far as I can.

The European system is stereotyped, and strangles many a mind of an original and initiative turn. The preparation of a European medical student requires thirteen years. From his sixth to his tenth year he is in the grammar school, from the tenth to the nineteenth year he is in the "gymnasium," where most of the time is

devoted to Latin and Greek. He would be much better prepared for the profession of medicine if he gave more time to modern languages, mathematics, natural history, chemistry, and physics. In the four years of professional study he has to proceed so systematically and attend so many lectures, that often enough his patience is worn out by the theoretical exposition of a subject before any allusion is made to its practical importance. It wearies him; he becomes inattentive and plays truant. Let me illustrate this by an example. Zoology is one of the obligatory studies in Germany. A friend told me that when he was at Würzburg, the lecture on zoology was from one to two o'clock every day, immediately after dinner. One hot summer day, while the professor was lecturing on whales, he fought a desperate but unsuccessful struggle with Morpheus. The professor's words grew faint and fainter, like distant bells, till at last he fell asleep and only awoke when the bell was rung just in the midst of the professor's closing sentence, of which he caught only the last part, viz., "and therefore the whalers always place themselves on the left side of the animal." You do not know, said my friend, how much annoyance that nap has given me. I could not ask the professor, and since that time I have asked hundreds of people why it was that the whalers always try to get on the left side of the whale, but up to this day I have not yet received a satisfactory answer. Whether this story was original with my friend or not, I do not know; but it suggests the first advice, gentlemen, which I venture to give you: Do not sleep during a lecture.

If I were still young, I would read a little less Greek and try to get over my zoology before I entered a medical college. You must not think, however, that I consider the study of the classics, Greek in particular, as useless or superfluous. I do not think that a liberal education is complete without Latin and Greek. Apart from the intrinsic beauty and educational importance of the classics as a means of training the mind, Greek and Latin words form so large a part of our scientific vocabulary, and Latin is still daily so much used in prescriptions and medical literature that no physician can get along without them. But I protest against the inordinate time devoted to them in the European and also in the American colleges. That that time could be employed on more important subjects, is tersely expressed by these words of a German satirist: "If the Romans had been obliged to learn Latin as we are, they would never have found the time to conquer the world." It is said of the Germans that they think their time unlimited, and waste it in preliminaries. A German author, for instance, who wants to describe the history of a city, begins with the creation of the world. Permit me to recall to your mind that Washington Irving has done the same thing regarding this glorious metropolis, and that the American academic colleges are not a whit better than the German. Take Harvard as an example. The average age at which a boy enters the academic department is eighteen or nineteen years, and his brain must be pretty well stocked with Latin and Greek to make the entrance possible. To acquire the college degree costs four years more, during which his mind is fed again chiefly with Latin and Greek. After this college education he proudly enters the medical department, where he has to spend another four years. Then he would like to travel and see how they cure people on the other side of the Atlantic. All this, if his health be not broken, may make him a model student, but he will be a pretty old boy before he earns the first dollar, and circumstances may make it highly desirable for him to earn a dollar or two, or three, before he gets very old.

As to *preliminary knowledge*, it matters little where and when it is acquired. I consider it necessary, gentlemen, to know Latin grammar enough to write simple sentences correctly, and to read easy prose—for instance, Cæsar—without much preparation; to know Greek enough to be acquainted with the general spirit of the language,

with the laws of the formation and derivation of words. It is horrible to read in print of *prodromata glaucomæ*, of the *fenestrum ovalis*, and the like. In mathematics the principles of algebra, plain and solid geometry, and trigonometry with logarithms, are indispensable. In natural history, chemistry, and physics only the rudiments are needed, for these sciences, so far as they have a practical bearing on medicine, will be thoroughly taught in the medical colleges—at least they are in this one. I regard it as self-evident that every medical student must be fully conversant with the English language; and it would be very useful if he could read German and French without effort. Those of you who have not had the good fortune to learn these preliminaries in younger years I advise most earnestly to do so later, and to devote a certain time to it every day.

How to arrange your professional studies to the best advantage. Here comes in the question of the superiority of a graded course over the one-class lecture system. To advance from the simple to the complicated, from the lower forms to the higher, is decidedly a good educational principle, and for the exact sciences, mathematics for instance, no other method could be advocated. But in sciences such as medicine, in which a vast, I may say the greater amount of knowledge has to be acquired, not by reasoning, but by experience, it is a positive advantage to lead the student from the first day straight to the field of observation. There at once his attention is engaged, his interest awakened, his sympathy with human suffering incited, and the desire to help becomes a passion. Correct diagnosis is fascination, healing the purest happiness. Thus from the very beginning the student will become enthusiastic in his profession; and enthusiasm is the mightiest stimulus to work. It is objected that a young student cannot fully understand a clinical demonstration. This is true, but he will be able to understand some, and if the teacher be good, even a good deal of it, so that the student may, in one clinical hour, gather more useful information than from a text-book in ten hours. Are text-books, are lectures unnecessary? By no means. Text-books have to be studied faithfully, and with patience and leisure, because they are the complete and well-arranged repositories of our stock of knowledge, of which the richest and best conducted clinic can impart only fragments. Lectures, gentlemen, are the easiest and most impressive way to acquire the greatest amount of information in the shortest time. An harmonious combination of all the means of instruction is the best manner of learning. The clinic will show you the object of your studies; it puts the questions which you have to solve, and is the mightiest incentive to scientific work. The sick-room will drive you to the lecture-room and to the laboratories, the chemical, physical, physiological, and pathological workshops where you have to try your hands on lifeless objects until you have acquired sufficient skill to manage the ailments of living human beings. The operating theatre demonstrates the importance of the dissecting-room and of the collection of instruments and apparatus. The disorders of the nervous, visual, and acoustic organs will urge you to visit the cabinets of electricity, optics, and acoustics.

Use them all, gentlemen, all the means of information. Do not pass the whole day in the lecture-room and the evening in "quiz" classes, as by so doing you may at the end of your studies be able to pass a brilliant examination in writing, but unable to distinguish intoxication from apoplexy, scarlet fever from nettle-rash, a gathering in the ear from meningitis. On the other hand, do not lounge the whole day in dispensaries and hospitals, observing symptoms and witnessing operations. This plan is too apt to lead to unreasonable empiricism, whose votaries are satisfied when they have filled their note-books with prescription formulas of cough-mixtures, anodynes, nerve-tonics, alteratives, hypnotics, cosmetics, antipretics, and purges. While at the college, employ the chief part of your time to learn how to diagnosticate.

Almost everything else you can learn at home. To become a good diagnostician, which is the next thing to being a good physician, requires a teacher and abundant and well-selected clinical material, which you cannot expect to find in the first years of your practice. Weakness in diagnosis does more harm than all other shortcomings together. Without a correct diagnosis, a trustworthy prognosis and a judicious management of a case are impossible. Gentlemen, the diagnosis and the prognosis, not the treatment, make the physician, in the eyes of the public. I emphatically repeat these well-known truths, warning you not to neglect the scientific foundation of the art of healing while collecting a set of recipes, nine-tenths of which are useless. Do not fight symptoms with drugs before you have carefully searched for the cause of the symptoms. The poorest pathologist always prides himself on his therapeutical greatness. There is, in every science, a mythological part which is handed down from generation to generation, whose disbelievers formerly were crucified, now are ostracized. Shall I tell you where the mythology of medicine is stored up? In the handbooks of *materia medica*, *allopathic* as well as *homœopathic*. But do not think me a nihilist. If I believe that nine-tenths of what is said of the virtue of drugs is myth, I am convinced that the last tenth is a blessing to mankind.

I have ventured to give you only some general advice how to study, leaving the special arrangements to the teachers of the different subjects.

I come to the last part of my address: *What opportunities for your studies does this college offer you?* It offers all you can desire, and more than any one of you can make use of. Chemistry and physics are well taught, and I am happy to say, that Professor Draper lays more stress on physics than is commonly done. Its importance is at least equal to, in my opinion greater than, that of chemistry. In anatomy, not to speak of the teaching, the material and facilities for practical work are unsurpassed. All the other branches receive due attention. The large general hospitals, Bellevue and Charity, in which the clinics are held, are before our door, and contain eighteen hundred beds, which are always occupied.

Other hospitals of a more special character are near at hand and equally at your service for clinical instruction. The dead houses of Bellevue and Charity hospitals furnish abundant and freely available material in that most important of all the auxiliary departments of medicine, pathological anatomy. The different laboratories contained in the new wing of the college building, inaugurated last year, have proved a great success, and invite your attendance and appreciation. You receive there gratuitously private instruction for which in Europe you would have to pay high prices, as the assistants of the European schools make their living more or less from such courses. Every branch of medical study, theoretical and practical, is taught in this college. What else can you desire? The opportunity is given, it is for you to avail yourselves of it. You are at liberty to map out your own path of instruction, to gather much information or little. The freedom of learning is as fully granted here as at any German university. You are considered as men ripe enough to judge for yourselves, and select what is best for every one of you. The college-bred scholar has only to look over the catalogue to lay out for himself a systematic graded course of three or four years' duration. The German student does the same. The scientifically less prepared, but mentally no less strong student, may choose the practical method, gather all the information which the clinics and lectures afford, and fill in what he lacks in theoretical knowledge during the evening and the vacation. Though, perhaps, he will not greatly advance the science of medicine, he can doubtless become a competent physician and a successful practitioner. The European universities do the same as our schools. They exclude nobody from availing himself of all the resources

they possess. They matriculate and promote everybody without distinction, and at the same rates, which is honest enough. It is not the medical departments of the European universities that demand a certificate of maturity; it is the State that refuses admission to the final examination by which the license to practise is granted if the candidate cannot produce a college certificate of maturity and evidence of four years' professional study at one or several universities. Whether in this country, sooner or later, the State will or will not take the final examination of the physician in hand is not for me to guess at. Thus far the licensing power is granted to the medical schools, and the time will soon come when you will have to present yourselves ready to answer questions in the seven topics.

Seven topics! Are there only seven topics in the vast domain of medical science? If you say there are seven chief branches, the remainder are "specialties" of which the candidate need know nothing, you are mistaken. There are no specialties; the human body is an harmonious whole, nothing can be left out or set aside as serving a special, extraneous purpose, not even a tooth. The scheme of examination by speaking of seven branches, means that the whole of medicine is classified in seven larger divisions, each of which will have to be subdivided, but none of the subdivisions must be ignored. The faculty desire it to be understood that all the subjects that are on the programme are worth knowing and of importance. They desire it to be understood that all branches of medicine—may they be taught by the regular professors or may they, for the sake of convenience and efficiency of instruction, be placed in the hands of special teachers—will be examined into according to their respective dignity. Some of these so-called specialties have acquired an extent of theoretical and practical significance, not inferior to some of the seven branches. I will mention, for example, ophthalmology, which is commonly regarded as a part of surgery, but which has acquired such an importance in internal medicine that Nothnagel, professor of theory and practice at Vienna, said last year that no medical man should be licensed who could not handle the ophthalmoscope. It will not do, gentlemen, to march so directly toward the programme for your M.D. that you leave unnoticed vast domains of the science and art of medicine, because you think they will not be subjects of examination. The specialties will come under the head of one or other of the seven branches and be examined by the official teacher of that branch, the questions to be formulated either by the professor or by the special teacher. In ophthalmology, for instance, two questions will in future be regularly given to each candidate for M.D., the one by the professor of internal medicine, the other by the professor of surgery. Skin diseases, nervous and mental diseases, ear diseases, throat diseases, etc., are all most important parts of medicine. Patients affected with them will demand your services daily. By requiring sufficient knowledge in these branches, and providing you with the means of obtaining it, the faculty does you a favor and a service, for which you will bless it all your life.

Let me now say a word about *post-graduate instruction*. Those who want to go beyond the requirements for their diploma will find ample opportunity to do so in this college, and in the different hospitals and other institutions of this city and this country. He, however, who feels the sacred fire in him will not be afraid to cross the ocean in order to perfect himself in Europe. Let full liberty prevail in all this, let every one choose and act for himself, and let it be recognized that we must and shall have physicians in this country to whom the management of the most important diseases may be entrusted with the same confidence as to the first European authorities. This city certainly will not lack such physicians, according to the stubborn law which governs the relation between labor and reward. This law throws the best men where work is best rewarded.

Ten years ago I was consulted by a Boston physician for a serious ophthalmic difficulty. I advised him to stay in New York and have his eyes treated. He asked me, quite astonished: "Why, haven't we as good physicians in Boston as you have in New York?" I replied without feigned modesty: "No, sir, and you never will have; for talent, like merchandise, has a tendency to seek the best market." He understood, stayed, had his eyes cured, and soon afterward settled in New York himself.

Gentlemen, as civilization advances with the progress of science, the requirements of a candidate will be greater from year to year. The faculty of this college have the earnest desire, and make every effort in their power to advance the standard of proficiency of the students. Last year they added the laboratories and section teaching, this year they have founded the *College Dispensary*, in which the students have an opportunity to make themselves acquainted with the milder and more common forms of disease, for which people are not admitted to hospitals.

You see, gentlemen, there is every opportunity afforded for a thorough medical education. What method you pursue is indifferent, only follow it up. In learning languages there are also two methods: 1, the *systematic*, which begins with the declension of nouns and goes regularly through all the chapters of grammar, etymology, and syntax, before the pupil reads the simplest book; and 2, the *practical* method, which begins with sentences, from the start, and deduces the rules of grammar from examples in speaking and reading. This method has appropriately been called the *natural*, for it is the way in which the child learns its own language. Who can say which of the two methods is the better? The systematic is more adapted to the scholar, the natural preferable for the requirements of practical life. In both methods, however, a given amount of work has to be done. There are in the English language, for instance, thirty-six thousand words which have to be committed to memory in some way or other. This requires time and work. The same in medicine. Its large stock of knowledge can be acquired only by hard and persistent labor. If any one of you thinks himself capable of getting a sufficient knowledge of the essential parts of the theories and practice of medicine during two college courses of twenty weeks each, he is fundamentally mistaken. I advise every one of you, in the name of the faculty, so to arrange your curriculum as to attend three full terms at the college, a winter and a summer course making one term. The old philosophers held it to be the highest maxim, "Know thyself;" Carlisle says, in modern times the maxim should be, "Know thy work and do it." Both are good maxims. Gauge your own faculties, examine the task before you, plan your work carefully, begin without delay, and do not stop till you have reached the end.

This, gentlemen, reminds me that it is time for me to stop, and for you to begin.

THE SECRET OF LONGEVITY.—A French medical man, who has just died at the age of one hundred and seven, pledged his word to reveal the secret of his longevity, when no more, for the benefit of others. It was stipulated, however, that the precious envelope containing the recipe for long life was not to be opened until he had been buried. The doctor's prescription, now made known, is simple enough and easy to follow, but whether it is as valuable as he pretends is extremely doubtful. He tells his fellow-men that if they wish to live for a century or more, they have but to pay attention to the position of their beds. "Let the head of the bed be placed to the north, the foot to the south, and the electric current, which is stronger during the night in the direction of the north, will work wonders on their constitutions, insure them healthful rest, strengthen their nervous system, and prolong their days." It is, he adds, to scrupulous attention to the position of his bed that he ascribes his longevity, the enjoyment of perfect health, and the absence of infirmity.

REPORT OF A CASE OF ACUTE FATTY ATROPHY OF THE LIVER, WITH POST-MORTEM EXAMINATION.

By S. C. CHEW, M.D.,

PROFESSOR OF THERAPEUTICS AND CLINICAL MEDICINE IN THE UNIVERSITY OF MARYLAND.

THE following case is reported as a typical instance of a malady of not very frequent occurrence, in which the diagnosis, though attended with some difficulty, was made during life, and completely verified by a post-mortem examination.

J. G.—, a most faithful and exemplary member of the medical profession, was engaged in his usual duties until Sunday, July 15, 1883, when he suffered from a severe attack of gravel, the calculus passing apparently along the left ureter.

To relieve the pain he inhaled in the course of Sunday morning about three ounces of chloroform without much benefit, the suffering returning as soon as the influence of the anæsthetic passed away. In the afternoon his friend and medical attendant, Dr. W. F. A. Kemp, was summoned to see him, and immediately administered a hypodermic injection of morphia, with the effect of at once relieving his pain and giving him sleep.

On the following day he was free from pain and attended to his professional duties, as he did throughout the week and until Wednesday, July 25th, though he spoke of feeling badly, and to those who saw him he appeared far from well.

On Thursday, the 26th, he went out in the morning, but came home with a severe chill, which was followed by fever, in which the temperature rose to 103.5°. Persistent nausea and vomiting occurred, with pain in the back, chest, and limbs, and oppression of breathing. The symptoms being like those of remittent fever, his physician prescribed for him the sulphate of quinia together with the salicylate of cinchonidia, under which the temperature fell to 99°, but in other respects his condition remained nearly the same for the two following days.

On Saturday, the 28th, the pain in the chest and oppression of breathing suggested the possible existence of a central pneumonia, as yet not extending to the surface so as to be detected by the ear; and under these circumstances I was kindly invited by Dr. Kemp to see the case with him. The nausea and vomiting were still continuing, the ejected matter consisting chiefly of mucus and watery fluid without any discolorations; temperature 103°. There was a slight icterode hue of the skin and conjunctiva. The patient, though evidently suffering from pain and oppression in the chest, was calm and uncomplaining. A very careful auscultatory examination made by both Dr. Kemp and myself showed no sign of pneumonia. The symptoms still appearing like those of malarial fever of a remittent type, it was decided to continue the use of quinia in somewhat larger doses. On the following day, Sunday, the 29th, the nausea and vomiting had diminished, and the temperature was 98.5°.

On Monday, the 30th, the patient expressed himself as feeling better, and read the newspaper in the morning, but occasionally some wandering of mind was observed, and in the evening the jaundice was more marked.

Tuesday, 31st.—In the morning some degree of somnolency was apparent; the jaundice was still deeper, and the temperature had fallen to 97.5°. Percussion over the liver appeared to show some lessening of the area of hepatic dullness, but as the abdomen was very large and fat it was impossible to pronounce positively from this method of investigation as to whether the liver was diminished in size or not. At 5 P.M. it was found difficult to arouse the patient, and at 8 P.M. the stupor was still deeper. This condition continued all night.

Wednesday, August 1st.—At 11 A.M. the patient was profoundly comatose, and it was impossible to arouse him. The bladder had been evacuated involuntarily, and some blood had been passed from the urethra, not diffused through the urine apparently, but staining the sheet in spots. On passing a soft catheter into the bladder, urine to the amount of about two ounces was obtained, which was healthy in appearance, contained no blood, was of normal specific gravity, and showed no albumen when tested with heat and nitric acid.

The diagnosis of the case appeared now to lie between four affections: first, pernicious remittent fever; second, yellow fever; third, uræmic coma; fourth, acute fatty atrophy of the liver.

The first of these diseases was excluded by the consideration that quinia had been freely given, and that under its use perfect apyrexia had occurred.

The occurrence of yellow fever in a single sporadic case was impossible in the highest degree, as no instance of the disease has been known in Baltimore this year, and the summer has been remarkably cool, and not of that continuously elevated temperature which seems necessary for the development of yellow fever.

The suspicion of a renal origin of the symptoms, suggested by the coma and the constant recurrence of nausea and vomiting, was negatived by the result of the examination of the urine.

There remained, then, the fourth alternative—acute fatty atrophy of the liver; and after fully weighing all the facts in the case, the opinion was formed that this would be found to be the organic disease upon which the symptoms of the case depended.

The patient died comatose about 6 P.M. August 1st.

On the afternoon of the following day a necropsy was made by Dr. J. E. Michael, Professor of Anatomy in the University of Maryland. The lungs were found to be hypostatically congested, especially in the lower and posterior parts, but no pneumonic change was present. The heart was soft and largely overlaid with fat; its valves and orifices were healthy.

The abdominal parietes contained a very large amount of fat, as did also the omentum.

The stomach contained a good deal of dark fluid, evidently consisting in great part of altered blood, and resembling the black vomit of yellow fever.

The kidneys were dark in color, somewhat mottled, and surrounded with an unusually large quantity of fat; but they were not organically altered.

The liver occupied not more than one-half of the space which it would be expected to fill in the abdomen of a man as large as was the subject of the examination. When removed from the body, it weighed exactly 31½ ounces, or about one-half of its normal weight, which, in such a subject, should have been about sixty ounces.

In the only case of acute hepatic atrophy reported by Dr. Murchison, in his work on "Diseases of the Liver," that of a young girl aged nineteen, the organ is said to have been "extremely small, weighing only 28 ounces, or exactly one-half of the standard weight for the girl's age."

In a case recorded by Professor Flint, Sr., which was also one of a young female, aged twenty-one, the liver was reported to be much reduced in volume, weighing 29 ounces.

Now, if these weights, 28 and 29 ounces, indicate a very remarkable reduction in the size of the liver in young females, as they certainly do, the weight of 31½ ounces, as met with in the liver of a large man, would show proportionately fully as great a diminution of its normal bulk.

This alteration of the size of the liver excluded entirely the diagnosis both of remittent and of yellow fever, for in both of these diseases the liver is either larger, or, at any rate, not smaller than natural; while it is generally of a bronze hue in the former disease, and of a straw-color in the latter.

In consistence the organ was very soft and friable, and it presented the appearance of being much congested, being dark in color, but not of the deep ochre or rhubarb hue described by some observers. A portion of it was examined with the microscope by Dr. J. E. Atkinson, Professor of Pathology in the University of Maryland, and was found to have lost almost every trace of normal liver structure.

A certain amount of connective-tissue was present, but no hepatic cells were discoverable, and in their place large quantities of oil-globules and granular matter were found.

The small amount of urine obtained before death was alkaline in reaction and contained some bile-pigment; crystals of triple phosphate were visible under the microscope, together with a few hyaline casts. An examination for leucine and tyrosine gave negative results, but the absence of these products did not affect the diagnosis, for, as is remarked by Dr. Murchison, "the detection of these crystalline bodies in the urine of a case of jaundice may be said to clinch the diagnosis of acute atrophy of the liver, but the failure to detect them must not exclude acute atrophy from the diagnosis."

The verification by the post-mortem examination of this case of the diagnosis of acute fatty atrophy of the liver was complete. The case was *acute*, for until seventeen days before his death the patient was attending to his usual duties, not suspecting the existence of disease. The change in the liver was *fatty*, as shown by the destruction of its normal tissue and the presence of a very large quantity of oil-globules. The change was *atrophic* in character, as the organ was of only about one half of its normal weight.

Two circumstances, the sex and age of the patient, rendered this case one of especial interest. The disease is much more common in females than in males; of 31 cases collected by Frerichs, 22 were females. The age of the subject of this report was about sixty, whereas a large portion of those attacked with the disease are under middle age. Of Frerichs' 31 cases 26 were under thirty, and all except two under forty.

Little or nothing is known of the originating causes of acute atrophy of the liver, nor of the primary changes in the nutrition of the organ which lead to an acute fatty degeneration. The malignant jaundice of the older writers was believed to be sometimes superinduced by mental emotions of a depressing kind, the *pathemata mentis* of Cullen, especially fear and grief. Sometimes, according to Sir Thomas Watson, it has been produced by great bodily suffering, or by a severe surgical operation, or perhaps by the dread which attended it. When resulting from nervous influences, it is observable, he remarks, that the cases "are often fatal, with head symptoms, convulsions, delirium, or coma supervening upon the jaundice." It is highly probable that in such cases the structural disease upon which the symptoms depended was that which later observations have shown to be acute fatty atrophy of the liver; and it is conceivable that in the case here reported the severe pain attending the passage of the renal calculus may have first started the morbid action by which the nutrition of the liver was fatally deranged.

OVARIOTOMY IN A CHILD EIGHT YEARS OLD.—Dr. Duchamp recently performed ovariectomy in a child eight and one-half years of age. The cyst was tapped and about a quart of lemon-colored fluid extracted. Then the tumor with the left ovary and Fallopian tube was removed. The operation was easily performed, and the child made a good recovery. The author recalls other cases in which the operation has been performed on young girls, and in which the favorable issue has shown the wisdom of operating thus early, and of not waiting until the tumor has grown to such a size as to endanger the life of the child.—*Journal de Méd. et de Chir. Prat.*, September, 1883.

A CASE OF EPITHELIOMA ORIGINATING IN
ABSCCESS OF THE LACHRYMAL SAC.FROM THE PRACTICE OF DR. C. R. AGNEW AND DR.
D. WEBSTER.

By DAVID WEBSTER, M.D.,

PROFESSOR OF OPHTHALMOLOGY IN THE NEW YORK POLYCLINIC.

Mr. K—, a Connecticut farmer, had lachrymal abscess at the age of forty-five, and was always afterward troubled with stillicidium, or a "watery eye." He consulted an eminent ophthalmic surgeon in 1872, thirteen years after the occurrence of his attack of acute dacryocystitis, and was advised to have an operation performed for opening his tear-passage, but neglected to attend to it. So the disease was without treatment until January 14, 1875, when Mr. K— came to New York and put himself under our care. He was then sixty-one years of age, and the lachrymal disease had existed for fifteen or sixteen years. There was a tumor of the size of a Lima bean over the tear-sac, and on its surface was an ulcer covered with a scab. Pus could be squeezed from the lachrymal sac. The eyeball was red, and there was some superficial vascular keratitis. There was no pain in or about the tumor, but "a little trifling itching." The vision of the eye was $\frac{2}{3}$.

We made a diagnosis of probable epithelioma, and Dr. Agnew removed the growth with a knife and placed it in the hands of Dr. Elijah A. Maxwell for microscopic examination.

Dr. Maxwell reported as follows:

"January 26, 1875.—I have examined microscopically the specimen, and herewith append what has been disclosed. The growth has a connective-tissue stroma made up of moderately large, spindle-shaped, nucleated cells; next, an infiltration of numerous round cells, resembling granulation tissue in form and arrangement of cells, and found most numerous in the central portions of the tumor, while the main bulk of the growth is made up of distinctly epithelial elements, showing the following varieties of cells. They were ovoid, polygonal, conoid, at the borders serrated, all with a large nucleus almost filling the cell and containing numerous nucleoli. Patches were found at the borders presenting the same appearances as the endothelium of lymph spaces, and giving one the impression of the probability of growth in this direction. It is, in my opinion, an *epithelial carcinoma* of the small-celled variety."

February 22, 1875.—The wound made by the removal of the tumor has entirely healed. There is still pus in the lachrymal sac.

Dr. Agnew now slit up the lower canaliculus and passed a narrow, probe-pointed knife down through the nasal duct to the nose. The passage was kept open by probing for a time and then the patient was allowed to return home.

October 21, 1876.—In about two weeks after the patient ceased to visit us two little nodules appeared in the same position from which the original tumor had been removed. They are now of the size of a small split pea each. The eye is the seat of chronic conjunctivitis and a glairy-looking pannus, as though there might ultimately be epithelial trouble of the cornea. The palpebral conjunctiva of the upper eyelid also looks threatening.

Mr. K— was advised to have the two recurring growths removed, but declined to have them interfered with at that time.

We did not hear from him again until September, 1883, when his nephew called at our office and completed his history. He stated that after the patient called upon us for the last time the growth increased rather rapidly, and became painful, always worse on taking cold. After about two years it had grown to a considerable size, and he placed himself under the care of a cancer doctor who put on a cancer plaster and "drew it out by the roots." The operation extended

through some weeks and was very painful, but the tumor was effectually destroyed, the site healed leaving a deep depression, and the growth never returned.

The patient died of typhoid pneumonia in March, 1881, after an illness of only eight days. It was his third attack of pneumonia, the first having occurred about fifteen years before his death, and the second within a few years of the first. There was no family history of cancer.

266 MADISON AVENUE.

THE DIAGNOSIS AND HYGIENE OF TYPHOID
FEVER.

By E. HOCHHEIMER, M.D.,

ASSISTANT SANITARY INSPECTOR NEW YORK HEALTH DEPARTMENT.

HAVING been assigned by the Board of Health to the investigation of the sanitary conditions attending or causing typhoid fever, several circumstances regarding its etiology and diagnosis have forced themselves upon my notice, to which, as they differ somewhat from generally received opinion, it appears advisable to call the attention of the profession, especially at the present time, when the disease is encountered with such unusual frequency.

Judging from the clinical picture of typhoid fever as usually given in the text-books, its diagnosis would seem an easy matter. The malaise which precedes its advent, the chill which marks its onset, the headache, epistaxis, diarrhea, abdominal tenderness, ileo-cæcal gurgling, roseola, tympanites, enlargement of the spleen, cough, appearance of the tongue, and, above all, the peculiar, regular remissions and exacerbations of the fever, make up a group of symptoms which stamp the features of a disease easily recognizable and not to be mistaken. Whatever may be the cause, whether the above description is a mere generalization, or whether there is something about the climate and hygienic condition of this city which materially modifies the appearance of the symptoms, I shall not stop to speculate. The fact, however, remains, that in the great majority of cases as at present met with, the task of arriving at a positive opinion is by no means an easy one. As a rule, this is not accomplished until the second or even the third week; and it is not magnifying the difficulty of making a diagnosis to assert that, in most instances, there is none of the exanthematous or zymotic diseases which it is so hard to recognize early. And yet this early recognition of the disease is of the highest importance, for many reasons: it will aid the attending physician to discover the conditions producing or assisting to cause the disease, lead to the use of proper precautions to prevent its spread, direct the correct line of treatment, and enable him, in uncomplicated cases, to foretell its natural course and duration, and thus keep the friends and relatives from expecting impossibilities, and dooming themselves to inevitable disappointment.

The disease ordinarily begins in a manner resembling an attack of malarial fever. The patient complains of weariness and inaptitude for exertion, and there is generally more or less elevation of temperature. There may be a chill, but this is the exception and not the rule; the same is true of the epistaxis. The condition of the intestinal action is variable: in many, diarrhoea is present, while in probably an equal number the movements are natural or the patient is even constipated. The appearance of the tongue is equally uncertain: sometimes it is coated, sometimes dry, sometimes almost normal. The coating, when present, may be white, yellow, or brown, and situated at the base, at the sides, at the tip, or in the centre; in short, it shows nothing more than is to be seen in any fever or inflammation. Abdominal tenderness is a more constant symptom, but not by any means met with in every case; in some instances it is probably present, but the patient's mental hebetude prevents its being appreciated. The cerebral symptoms are very irregular: while many subjects complain of

headache, or a sense of fulness across the forehead, others do not deviate in this respect from their usual condition. The "characteristic temperature curve" of the first week will seldom be observed.

The above hasty glance at the more common manifestations of the disease in question would apparently leave us in a very uncertain state of mind, in the first few days of the sickness, as to the nature of the patient's complaint. This is undoubtedly true, except where there has been another case of typhoid fever in the house shortly before, the diagnosis must be mainly made by exclusion. But the darkness is not so profound as it may, at first sight, appear. In the first place, there is the fever, more or less continuous; secondly, in addition, there are generally one or more of the other symptoms, and in this disease, to borrow a phrase from homœopathy, it is especially necessary to have in view "the totality of the symptoms;" thirdly, any case of "malarial fever" which persists longer than three days in spite of sufficient administration of quinine should excite suspicion of typhoid; and lastly, there is a symptom which is peculiar and so constant that it may almost be regarded as pathognomonic, *the roseola*.

The time at which these spots appear varies; they may be met with as early as the third day or not until the end of the first week. Nor are they always, strictly speaking, on the abdomen; they occur sometimes on the pubes, or, perhaps most commonly, over the lower ribs. Neither are they always confined to the trunk; in exceptional cases they invade the extremities as well, and this without any apparent relation to the severity of the attack. In size they are from the one-thirty-second to the one-sixteenth of an inch in diameter, depending upon the character of the skin, being smaller in young subjects and in those who have delicate skins. The same remark applies to their elevation above the surrounding integument; they may be not at all raised, or elevated almost to papules. They are smooth, and, when they are most palpable, in running the finger over them but a slight resistance is encountered. In color they are bright red, and they *disappear completely on pressure*, showing again quite promptly when the pressure is removed, the rapidity of their reappearance depending of course on the activity of the circulation. In number they vary within wide limits; there may be only one spot in the course of the disease, or, as stated above, there may be an eruption covering the greater part of the body and coming out in successive crops. But whether they be few or many, their presence is almost constant, and, if carefully looked for, particularly during the second week, they will be found in probably no less than ninety to ninety-five per cent. of all cases. In short, they are so peculiar and characteristic that they cannot fail to be of the highest diagnostic value.

The bronchitis, which generally shows itself at the end of the first week, is likewise one of the most constant symptoms; and while, of course, it may be accidental, taken in connection with the other symptoms it may assist in arriving at a conclusion in doubtful cases.

As to the sanitary conditions under which typhoid fever occurs, a few words must suffice. While it cannot be denied that in many, perhaps the majority of cases, no particular defect can be discovered, still in a very large number obvious cause can be found. Prominent among these may be mentioned untrapped or unventilated waste-pipes, leaky discharge-tubes, sewers, or soil-pipes, lack of water in the water-closets or school-sinks, and foul-smelling, badly cared-for privy-vaults. Where more than one case has occurred in a house, one or more of the above conditions will rarely be absent.

It would appear almost an impertinence on my part to say anything with reference to the precautions necessary to prevent the spread of the disease, and yet so frequently do both my colleagues and myself see them neglected, that it may not be out of place to call particular attention to them. It is apparently well established that the materies

morbi lies in the discharges from the bowels, and only becomes active after they have undergone a certain amount of decomposition or fermentation. The process of prevention is therefore simple and direct; all that is required is to thoroughly and speedily disinfect the stools or anything that has been soiled with them. Copperas is very good for this purpose, and has the advantage of being cheap and odorless. A solution of this should always be kept in the chamber or bed-pan, and when the patient has a movement of the bowels the vessel should be emptied at once and well rinsed and have some of the disinfectant again put into it. If the patient's linen or bed-clothes should accidentally be soiled, they should be changed at once and disinfected; for this purpose hot water is excellent, and the solution of chlorinated soda, known in the laundry under the name of Javelle water, is to be commended. The patient's undergarments, etc., should not be washed with the clothing of other members of the household. It is hardly necessary to add that to sprinkle carbolic acid or to strew chloride of lime about the sick-chamber is, to say the least, of doubtful utility. The practice of keeping the discharges for the doctor's inspection is a source of danger, and, except in rare instances, it should not be countenanced. These measures cannot be begun too early; the attending physician should not be content with giving general directions, but should lay down strict and minute instructions for disinfection, and by daily inquiry see to it that they are complied with.

207 EAST FIFTY-SEVENTH STREET.

POISONING BY SULPHATE OF ATROPIA.

SUCCESSFULLY TREATED WITH HYPODERMICS OF SULPHATE OF MORPHIA.

By LLEWELLYN ELIOT, M.D.,

ASSISTANT PHYSICIAN CENTRAL DISPENSARY WASHINGTON, D. C.; DEMONSTRATOR OF ANATOMY UNIVERSITY OF GEORGETOWN.

Cases of poisoning by atropia are becoming of frequent occurrence, more especially since the appreciation and application of its therapeutical effects increases. Ophthalmic troubles, rheumatism, pertussis, dysentery, the sweating of phthisis, poisoning by opium yield to its proper administration as if by charm. The dose for internal administration has been stated to range from .0005 gm. to .003 gm. ($\frac{1}{2}$ gr. to $\frac{1}{16}$ gr.). Like many other valuable remedies it is often abused. The following case was seen, in conjunction with Drs. J. I. Dyer and J. S. Harrison, during my service as Resident Physician to the Washington Asylum Hospital of this city.

Mary H—, white, aged forty years, born in Ireland, was admitted to hospital on December 11, 1881, for treatment for "double iritis" of short standing. She gave a history of frequent exposure and attacks of alcoholism and rheumatism, but nothing pointing to syphilitic taint. She was directed to use a solution of atropia sulphate, .133 gm. to 32 c.c. (gr. ij. to $\frac{5}{8}$ j.), applied night and morning; the strength of this solution was on December 16th increased to .266 gm. to 32 c.c. (gr. iv. to $\frac{5}{8}$ j.). No improvement following, she was on December 28th ordered potassium iodide, 1 gm. (gr. xv.) three times a day; emplastr. cantharid., .025 mm. (1 in.) square, to each temple, besides the following:

R. Massæ hydrargyri 8 gm. (gr. xij.)
Pulv. opii. 133 gm. (gr. ij.)

M. Ft. pil. no. xij. Sig.—One three times a day and continue until salivation appears.

On December 30th the blistering was repeated; on January 3, 1882, salivation appeared, for which she was ordered a wash of potassium chlorate, tincture of myrrh, and water.

From the commencement of the administration of the mass. hydrarg. until profuse salivation the iritis steadily improved, so much so that she assisted in a small way in

the ward duties. On January 19th, at 7.30 A.M., she took by mistake a teaspoonful of the atropia solution, .266 gm. to 32 c.c. (gr. iv. to $\frac{5}{8}$ j.), making her dose .033 gm. (gr. ss.). In a short time she complained of lightness of the head, and "feeling foolish;" nothing was thought of it, the mistake not being known. At 9.15, an hour and three-quarters afterward, symptoms of atropia poisoning developed. Pupils dilated, vision diminished, accelerated respiration, constriction of the throat, difficult deglutition, pulse 116, but weak. At 9.20 a hypodermic injection of morphia sulphate, .022 gm. (gr. $\frac{1}{2}$), was administered; at 10.20 it was repeated; at 10.50 a third was given, pulse, 96. At eleven o'clock the thermometer in the axilla registered $96\frac{3}{4}^{\circ}$ Fahr.; pulse, 96; respiration, 3 per minute, with marked symptoms of morphia poisoning. An electric battery was applied and in a few minutes another was brought into use. She responded. At 12.30, being placed upon the floor, she was subjected to violent shaking and flagellations at intervals. Her condition began to improve, at 4 P.M. she was given a few swallows of tea, for this strong coffee was substituted. At 9 she was put to bed. Her mind was not clear. During the following day her only trouble was partial loss of memory with muscular soreness. From this time she continued to improve; her sight being restored, she was discharged some weeks later. Nothing more was heard of her for some months, when in a drunken fit she jumped into the canal and was drowned.

The points of interest in the history of this case are, the complete cure of the iritis, the antidotal effects of morphia sulphate, the slowness of the respiration (3 per minute), and the subnormal temperature ($96\frac{3}{4}^{\circ}$ Fahr.). There can be no doubt as to the temperature, since it was taken with different instruments several times, for fear there might be some mistake in the reading or registering.

ADENOID VEGETATIONS OF THE PHARYNGEAL VAULT,

AND THEIR RELATION TO MIDDLE-EAR DISEASE.

By R. E. SWINBURNE, M.D.,

SURGEON TO THE HARLEM EYE, EAR, AND THROAT INFIRMARY, NEW YORK.

I PROPOSE to call attention to a class of cases that are comparatively common, accompanied by many unpleasant symptoms, and followed at times by quite serious results, yet frequently not recognized by the attending physician. Meyer, of Copenhagen, first called attention to this disease, and since then its symptoms, clinical history, and the histology of these growths have been so thoroughly studied and are so well understood that I shall not dwell long upon those points. The symptoms will depend upon how much respiration and phonation are interfered with, the amount of secretion, and to what extent the ears are involved. The nose is the natural respiratory channel, and no child will go about with its mouth constantly open when free nasal respiration is possible. In proof of this I cite the fact that in every case coming under my observation, in which a successful operation has been performed for the removal of vegetations, the patient has subsequently kept his or her mouth closed when at rest, although previously it had been constantly open. Phonation is very much hindered, especially in the pronunciation of the nasal consonants m and n. The term dead, applied to the voice by Meyer, describes it best and has been universally adopted. When the obstruction is considerable the nostrils are small, their walls thick and the nose compressed from side to side giving it a characteristic appearance. In a healthy and normal subject the anterior nasal openings are the smallest parts of the canals, and consequently when an extra amount of air is required the nasal wings are expanded and the orifices distended, but in these cases there is non-development from disease. If the children are

old enough they will expectorate the secretion, but if not it will be swallowed and coughed up, and this is not unfrequently the cause of a cough that resists all expectorants and anodynes. Sometimes it accumulates in such quantities as to interfere with respiration and wake the little patient several times during the night with a severe coughing spell.

Patients with a large amount of this adventitious tissue in the superior pharynx have a sallow complexion, which, together with the open mouth and compressed nostrils, gives them a characteristic distressed and idiotic expression, more pronounced if there is much deafness. So peculiar is the physiognomy in these cases that I have frequently been able to make a diagnosis from it alone as the patient entered my office or the infirmary, and in no case has my first opinion been proven erroneous by further examination.

All observers report this condition as existing in children of from five to fifteen years of age much oftener than at any other period; my own records show them in patients of from three to twenty-six years. A positive diagnosis can only be made by pharyngoscopic, rhinoscopic, or digital examination. Examination of that part of the pharynx below the soft palate frequently gives valuable information as to the condition of the membrane above, from the strings of mucus and crusts dropping down, the presence of enlarged glands on the posterior wall, and hypertrophied palatal tonsils; the naso-pharynx may, however, be almost entirely filled with vegetations without a trace of the trouble existing in the lower pharynx. The necessity of examining the whole surface anteriorly and posteriorly is therefore obvious. Pharyngoscopic examination sometimes requires considerable time and patience to determine accurately the condition in unruly children, and in such cases the parts should be examined by passing the finger behind the soft palate. In this way the whole space can be explored with perfect satisfaction to the surgeon and without danger to the patient, nor is this a painful manipulation. I usually make a digital examination in cases that readily permit of an examination with the pharyngoscope, in order to obtain more precise knowledge of the existing condition. My experience enables me to confirm the statement of Meyer, that the best place for observing this class of cases is among ear patients. He says ("Medico-Chirurgical Transactions," p. 191, London, 1870): "Among 102 cases of adenoid vegetations 72 suffered from disease of the ear. Among 2,000 children of the public schools of Copenhagen (the majority being between ten and fifteen years of age), he found 20, or one per cent. of dead pronunciation, and in all met with adenoid vegetations." At the Harlem Eye, Ear, and Throat Infirmary, since its organization in January, 1882, up to September, 1883, 179 patients suffering from middle-ear disease applied to me for treatment, and of these 27, or 1 in 6 $\frac{1}{2}$, had adenoid vegetations; 148 applied on account of throat and nasal afflictions, and of these 15, or 1 in 10, had this trouble, making a total of 42 cases among 325 throat and ear patients. Twenty-seven of the 42 cases of vegetations, or about three-fifths, had diseased ears. Of the 27 ear cases there were perforations in one or both drumheads in 14. While there was this large percentage of adenoid growths of the vaults there were only 7 cases of hypertrophied palatal tonsils, one-sixth as many as of the former.

Hypertrophied palatal tonsils have from time immemorial almost been looked upon as a cause of middle-ear disease and volumes have been written about it, while the more common and important subject of hypertrophied pharyngeal tonsil has been entirely overlooked, simply because surgeons did not employ the pharyngoscope, and consequently were of necessity entirely ignorant of the condition of the membrane above the palate. In my experience enlarged palatal tonsils is only a part of a general catarrhal condition of the upper air-passages, is, in the great majority of cases, accompanied by ade-

noma of the vault, and is very much less common than the latter. Among the patients who applied for treatment of middle-ear disease, not accompanied by adenoid vegetations, there was well-marked naso-pharyngeal catarrh in nearly every case. My patients suffering from catarrhal throat affections almost invariably tell me that at different times they have been somewhat deaf, had tinnitus aurium and other common symptoms of otitis media, but it soon passed off and they considered it a trifling matter. If the hearing power of patients suffering from nasal catarrh be carefully tested it will frequently be found less than normal, although the subject is entirely unaware of the defect. Careful inquiry and study of these cases has convinced me that middle-ear disease not secondary to and the result of disease of the naso-pharynx is uncommon, and that the pharyngoscope and rhinoscope are as essential as the otoscope in making a correct diagnosis and applying proper treatment. I feel I have not done my duty to any patient that applies to me for treatment of a middle-ear affection until the nose and superior pharynx have been thoroughly examined. Upon this point Politzer says ("Diseases of the Ear," p. 303): "Experience teaches that when the naso-pharyngeal affection ceases the consecutive inflammation subsides, but that in a number of cases the inflammatory swelling and secretion in the middle ear continue, with the development of all the consequences I have already enumerated. On the other hand, in primary, or even in secondary affections of the middle ear, the inflammatory process, especially the swelling of the Eustachian tube, is maintained and recovery hindered by complication with or continuance of a naso-pharyngeal affection. From this may be seen the importance of minute examination of the naso-pharynx and the employment of rational treatment for the removal of an existing naso-pharyngeal affection as one of the principal conditions for affecting a favorable result in the numerous obstinate cases thus complicated." The aural disease accompanying adenoid vegetations of the pharyngeal vault is said to have been produced in three ways: First, by the pressure of the growths upon the mouths of the Eustachian tubes; second, by their interference with the circulation of air through the nose; and third, by an extension of the inflammation to the middle ear. My own belief is that it is caused almost, if not entirely, by an extension of the inflammation, during an attack of acute naso-pharyngeal catarrh to which patients in this condition are predisposed.

Patients present themselves with aural catarrh and purulent middle-ear disease as the result of nasal catarrh many times more frequently than they do with these troubles in connection with adenoid vegetations. All of the cases of acute middle-ear disease accompanied by adenoid vegetations that have come under my observation, have also had acute pharyngitis. In the great mass of these cases, applying on account of the ear complication, the vegetations are so small as not to press on the tubes at all, and do not interfere with respiration sufficiently to prevent the proper amount of air reaching the middle ear. The question now arises, whether operation for the removal of the vegetations is advisable or not. No ill effects have followed operation in any of my cases, and I believe none need ever occur if properly performed, but, on the contrary, the ears and general health may be very seriously damaged if left to nature. These growths must, of course, be approached either through the nose or through the mouth from behind the soft palate.

There have been five methods proposed for their removal, and used with varying success: 1, the curette; 2, caustics; 3, galvano-cautery; 4, the wire loop, which may be either the galvano-cautery loop or the *ceraseur*; and 5, the forceps. The only difficulty experienced in removing a hypertrophied pharyngeal tonsil is its inaccessibility. The nostrils are narrow and slit-shaped, through which only the smallest instruments can be

passed, and any manipulation in these cavities is always accompanied with considerable pain, so much so that children especially are unable to maintain the quietude necessary for the successful and easy performance of the operation. A very large percentage of these cases are also accompanied by hypertrophic rhinitis, which still further encroaches upon the calibre of the canals. In many instances it is simply impossible to pass any instrument through one nostril, on account of a deviation of the septum or an exostosis. Although the passage through the mouth is large the obstacle that has always been experienced is the spasmodic action of the soft palate, which instantly takes place upon the slightest irritation of the pharynx, thereby cutting off all communication. Palate retractors have been devised and employed, but they have all hitherto required the use of one hand for their manipulation, a fact that very seriously affects their utility. The method of passing strings through the mouth behind the palate, out of the mouth and then tying the ends over the upper lip is a very useful procedure, but does not counteract the action of the levator-palati muscle and consequently is not an entire success. The desideratum has been an instrument that will at once keep the mouth open, the palate retracted, and overcome the action of the levator-palati muscle. These objects are obtained by the use of the instrument made for me by J. Reynders & Co. It consists of a mouth-gag, differing from Whitehead's only in the absence of

a tongue depressor and the addition of a palate retractor. The palate retractor, devised by myself, is a broad, flat hook with a small round shaft, having a thread upon its whole length and a nut. To the mouth-gag I have added a bar with a slot and slidebolt. When the gag is properly placed in the mouth the bar will be just beneath the upper incisor teeth and parallel to them. After the gag has been inserted between the teeth and opened, the retractor is to be hooked behind the palate, drawn forward, the stem inserted in the slot, the bolt shoved beneath it, thus firmly holding it in place, and finally the nut on the stem is to be screwed up. I have used this instrument in fifteen cases of adenoid vegetations of the pharyngeal vault and find it to be all that is desired. In doing this operation I always give ether, because, first, it is quite painful; second, in children it is sometimes difficult to see the throat, and always impossible to operate there without restraining them by force; and third, there is no objection to it. The curette was Meyer's instrument, but he distinctly states (*op. cit.*): "One operation rarely succeeds in removing all of the vegetations, so that it often requires to be repeated. When the vegetations are of soft structure I employ cauterization with the solid nitrate of silver. In some few instances neither the operation nor the after-treatment by the use of caustics and the pharyngeal douche has succeeded in removing all traces of the vegetations." He also reports severe reaction, which in some instances resulted in perforation of the drumhead.

This method of treating the affection was original with Meyer and used by him more than by any other surgeon. Therefore, after reading the above opinion of it by its author, no further argument will be necessary to con-

vince us that it is not all that is to be desired. The second and third methods—namely, destruction by caustics and cautery—act upon the same principle, differing only in degree. After a considerable experience with such caustics as the saturated solution of chromic acid, sulphate of copper, the tincture of iodine, etc., I have entirely abandoned them, convinced they are useless in any considerable hypertrophy. The galvano-cautery I have employed in a number of favorable cases, but have never succeeded in curing any of them. It is a very painful procedure, difficult to perform in adults, almost impossible of accomplishment in children, and requires several applications, extending over a period of weeks; serious damage to the healthy parts is unavoidable and the cauterization is always followed by a good deal of inflammatory reaction. In my opinion this treatment should never be employed in the naso-pharynx, although for the treatment of the extreme hypertrophies of the tissue covering the turbinated bones it has afforded me better results than any other agent. With the aid of a speculum and ivory slide, introduced by Dr. E. S. Shurley, of Detroit, the turbinated bones can easily be cauterized without endangering the healthy parts, and in my hands many cases have yielded to this plan of treatment that resisted all others. The fourth plan is either the galvano-cautery loop or the cold wire snare.

Before the introduction of the Jarvis snare I removed post-nasal growths with an *écraseur* mounted with copper wire, but found great difficulty in getting it through the nose and over the tumor, simply because it would bend whenever it impinged against the solid parts, and of course the same is true of the platinum wire, but the steel wire will spring over a tumor without bending, thus permitting the surgeon to draw it down to the base or pedicle, and by turning the nut cut it off. The Jarvis snare is a single round tube that can be readily turned in the nostril, while the cautery loop of necessity consists of two tubes, making it much wider and of course requiring a correspondingly larger space to be turned in. The former will cut off anything one is required to remove here, and as it is cheap and always ready, while the latter is both costly and troublesome, I much prefer the snare. The modification of the Jarvis snare for use behind the palate, introduced by Dr. Bosworth, is superior to any other with which I am familiar, but the objection to it is the tediousness of the operation to both surgeon and patient. Large growths can be removed in this way without trouble, but the smaller ones in children of from three to ten years of age, who come under the care of the aurist on account of the accompanying ear disease, are very difficult to treat by this method. Many of them are simply broad, flat cushions, attached to the vault without any constriction at the base, and to which it is almost impossible to attach a snare even in adults who will tolerate the pain and discomfort, but in children it is still more difficult, for they resist as much as possible. Removal of these growths by the snare through the nose is generally much more difficult than through the mouth.

We now come to the consideration of the fifth method—the forceps. Dr. Cohen, in his book “Diseases of the Throat and Nasal Passages,” p. 262, says: “When the vegetations are large and the parts can be educated to quietude under manipulation the growths can sometimes be seized with properly curved forceps and be torn off or crushed off as the case may be.”

This is as favorable an opinion as any one can give, unless the movements of the palate can be controlled. With the mouth-gag and palate retractor I have shown you, properly curved forceps, and the patient fully anesthetized, the whole growth can be removed while the patient is recovering from the anæsthesia. Everything that can be taken hold of with the forceps should be removed, and then the index finger should be passed behind the palate and any shreds or small pieces found are to be scraped off with the finger-nail. This opera-

tion is adapted to all cases, but especially to those in which the vegetations are small, and in children who will not tolerate operative interference. The great advantages of it are, that it is radical—that is, the vegetations are all removed at one operation, there is never any inflammatory reaction, and it can be performed in less time than any of the other operations. There is no more hemorrhage in removing them in this way than in any other, and it ceases spontaneously as soon as the operation is completed.

Most of these cases are accompanied by hypertrophy of the tissue covering the turbinated bones, and in those cases I apply the galvano-cautery to them after the patient has been anesthetized, but before removing the adenoid tissue. If this hypertrophied erectile tissue is not destroyed, the patient will still be unable to breathe through the nose, and I have not yet found any agent that acts so promptly and efficiently here as the cautery. Although there is always considerable inflammation following the use of the cautery, I have never yet seen any harm result from its use in the nose.

I wish particularly to call attention to the difference between its use in the nose and the naso-pharynx. In the nose the healthy parts can be protected, the application limited, and it is entirely under the control of the surgeon. In the naso-pharynx the healthy parts are seriously damaged, the mouths of the Eustachian tubes frequently more or less burned, resulting in acute inflammation of the middle ear, and all of the serious consequences so liable to follow. I very frequently employ the galvano-cautery in treating hypertrophic troubles of the nose, and have never seen any evil results from its use, but, on the contrary, have obtained very decided benefit in every instance.

The first case I operated upon in this way was S. C. B —, aged six, with chronic aural catarrh, hypertrophy of the turbinateds, and pharyngeal tonsil. He was referred to me by Dr. Ira B. Read, who kindly assisted me in the operation. The patient was etherized, the turbinateds cauterized, and the vegetations removed with the forceps, the mouth and palate being controlled by the instrument I have shown you. I did not see the boy again for some three weeks. At this time his mouth was firmly closed, although it had been constantly open before the operation, and upon examination the superior pharynx was found entirely free from vegetations, while the turbinateds were so much reduced in size as to permit of free nasal respiration. The ears were also very much improved, and have since given him no trouble. The mother volunteered the information that the bad odor of the breath, and all the other unpleasant symptoms from which he had suffered so long, had entirely disappeared, and she considered it a very successful operation.

Since then I have operated in this way fifteen times, and in only one case failed to remove the whole mass at one operation. In this patient there was a small piece left just back of the septum, and although it was so small as not to interfere with respiration, I removed it with the nail of my index finger. The final result of this case was a perfect cure.

PARALYSIS FOLLOWING SIMPLE CATARRHAL SORE THROAT.—Dr. Lentz reports in the *Gazette Médicale de Strasbourg* for September 1, 1883, two cases of catarrhal sore throat followed by grave visceral lesions. In the first case there was albuminuria, and in the second paralysis of the lower extremities and retention of urine. From a study of the cases he concludes as follows: 1. Simple catarrhal sore-throat may be followed by grave phenomena, such as albuminuria or paralysis. 2. It seems to be in some cases the manifestation of miasmatic poisoning. 3. The paralysis is the result of a direct and specific action of the virus, upon which depends also the sore throat, and is not, as claimed by some, due to weakness following acute disease.

Progress of Medical Science.

CROTON-CHLORAL IN THE TREATMENT OF PERTUSSIS.

—In a paper read before the Kentucky State Medical Society (*American Practitioner*, August, 1883), Dr. W. C. Webb speaks very highly of croton-chloral in whooping-cough. He has treated a large number of cases with this remedy, and claims to have obtained a cure in nearly every instance within two weeks. The drug must be given in large and continued doses to obtain the best results. To a child one year old he gives one grain of croton-chloral every four hours. Children from ten to twelve years of age will bear two grains at a dose. After the first week the cough is generally so much improved that the remedy may be given less frequently. It is, of course, necessary to watch carefully the effects of the drug, so as to avoid the production of toxic symptoms.

INTESTINAL OBSTRUCTION CAUSED BY A CALCULUS.—Dr. Magnin relates in the *Journal de Médecine et de Chirurgie Pratiques*, for August, 1883, the case of a lady who, for several days, had suffered from obstinate constipation, and complained of violent pain in the abdomen. Purgatives of various kinds were administered, during five days, without effect, except to induce bilious vomiting and increased pain. At the end of this time the obstruction was relieved by the passage of a calculus the size of a duck's egg, of ovoid shape, and rough on its surface. The composition of the mass was the same as that of biliary calculi.

TREATMENT OF WARTS BY CALCINED MAGNESIA.—Various contributors to recent French periodicals have been relating their experiences in the treatment of warts by the internal administration of calcined magnesia. They all report favorably concerning it. The plan is to give seven or eight grains of magnesia per diem, and a cure of the disfigurement is said to be obtained in the course of one or two months. Dr. Lucas Championnière (*Journ. de Méd. et de Chir. Prat.*, August, 1883) suggests the trial of this same remedy in the case of epithelioma, and thinks that possibly we might obtain equally favorable results in this affection also.

REFLEX PARAPLEGIA.—Dr. Thomas Oliver relates, in the *Liverpool Medico-Chirurgical Journal* for July, 1883, two cases of paraplegia associated with morbid conditions of the genito-urinary apparatus, which would seem to be confirmatory of the theory of the reflex nature of paralysis in certain cases. The first patient was a man, forty-six years of age, of temperate habits, and without any history of venereal disease. He was working one day in a garden, when he suddenly experienced a severe pain in the back, which became so intense that he started for home. Before proceeding far, however, he began to stagger and soon lost all power in his legs. A fortnight later he was brought to the infirmary in a condition of complete paraplegia. He still complained of pain in the back, and at night there was subsultus tendinum, during which the pain was more severe. There was difficulty in passing water, and the flow would sometimes be suddenly arrested. Exploration of the bladder with a sound gave negative results. The urine contained a quantity of pus, and on a few occasions he passed a little blood. There was no rigidity of the muscles, and the plantar and patellar reflexes were normal. A localized area of dulness, extending from the eleventh rib to the crest of the ilium was detected, which was also extremely painful on pressure. A renal calculus was suspected, and a long needle passed into the right kidney came in contact with a hard gritty substance. Under the influence of rest and remedies administered for the relief of pain, the patient recovered the full use of his limbs, and has remained well. The second case was that of a lady, twenty-eight years of age, who had completely lost all power in her legs. Sensation was normal, and there was no muscular

rigidity. Vaginal examination revealed the existence of retroflexion of a heavy uterus, the lifting up of which was painful. As she had not menstruated for three months there was a possibility of pregnancy. Complete return of power in the limbs followed treatment of the uterine condition. The loss of power was stated not to be hysterical. Dr. Oliver concludes, from a study of these and other similar cases, that paralysis may be purely reflex in character, and he thinks that the term reflex paraplegia should be retained in our classification of diseases.

CARDIAC ECTOPIA.—Considerable interest was manifested at a recent *séance* of the Académie de Médecine of Paris, by the exhibition of a case of pregnancy at the ninth month, by M. Tarnier. The woman was a secundipara, and the sternum was bifurcated at the lower part, so that the beats of the heart were seen to take place immediately beneath the skin of the epigastric region. It was stated that the ventricular part of the heart could be seized between the fingers; by palpation over the upper part of the notch the contractions of the auricles could be detected. Apparently the diaphragm does not exist at the site in question. M. Marey said that this specimen of teratology would no doubt permit a verification in man of observations made upon the heart of animals. M. Beau had explained the beat of the heart as due to dilatation under the influence of the afflux of blood at the time of the ventricular systole. According to him the apex of the heart contracts during the diastole. In the case of ectopia, on the contrary, it was easy to perceive that the ventricle was soft during the diastole and hard during the systole; in the latter period the apex of the heart strikes the thoracic wall.—*London Lancet*.

SURGICAL INTERVENTION IN TUMORS OF THE BLADDER.—In a memoir read before the Société de Chirurgie of Paris (*La France Médicale*, August 4, 1883), Dr. Bazy sums up the indications for operation in vesical tumors, as follows: 1, in the case of a pediculated tumor, an operation is justifiable whatever the functional troubles may be; 2, when the tumor is sessile, an operation should be deferred until functional troubles present themselves; 3, when the suffering is intense, and death is inevitable from the results of pain and hemorrhage, entire ablation of the organ should be practised, a hypogastric fistula being formed. The contra-indications are classed under four heads: 1, the generalization of the neoplasm; 2, close adhesions to other organs—the most that could be done in such case would be the establishment of a permanent fistula; 3, diffuse infiltration of the walls of the bladder by the new growth—in such a case a fistula, if established, would be speedily closed by the neoplasm; 4, acute nephritis or advanced secondary degeneration of the kidneys. A commencing lesion of slight extent might be arrested by operation upon the bladder. The best mode of operating, the author thinks, is by hypogastric section. This gives a large opening into the bladder, is seldom followed by any immediate evil results, and is the most convenient location in which to establish a permanent fistula. Hemorrhage is at first a little abundant, but it quickly ceases. Extravasation of urine is not to be feared, but of course, free drainage should always be provided for. Perineal section is much less suitable, except in a very small proportion of cases.

PAROSTEAL SARCOMA OF THE RADIUS.—The following case is related by Mr. Henry T. Butlin in *The Lancet* for August 11, 1883: A strong, healthy-looking man was admitted to hospital on April 8, 1882. On the radial side of the left forearm, about midway between the elbow and the wrist, was a tumor as large as a small fist, but lobed and elongated. It presented toward the front, as well as on the outer side. The tumor was tense, fluctuating on the outer side, but firm toward the front; the skin covering it was stretched, but not discolored. In the axilla was one enlarged gland about the size of a

small nut. The man said that for four months he had been conscious of the presence of a lump in the forearm; but it had grown very slowly, and without pain, and therefore had not prevented him from pursuing his occupation, until about six o'clock on the previous evening, when suddenly, without warning and without any evident cause, it began to enlarge, and in less than half an hour had doubled its previous size. The enlargement was accompanied with excessive pain, which at once rendered him incapable of continuing his work, and compelled him to seek advice. The diagnosis was sarcoma of the radius, probably subperiosteal, which had enlarged from sudden hemorrhage. He was put to bed, the arm laid on a rest, and cooling lotions were applied. But the pain continuing unabated, it was decided to operate. An Esmarch's bandage was applied, and then a free incision was made into the tumor. A large quantity of clotted blood was turned out, but the bone, contrary to expectation, was nowhere bare. It was decided, in spite of the apparently malignant character of the tumor, not to amputate, but to scoop out the new growth and endeavor to save the limb. This attempt was successful, and though two small recurrent tumors have since been removed from the cicatrix, the patient has a useful arm, and has remained free from any appearance of the disease in other parts. Microscopical examination showed the tumor to be a spindle-celled sarcoma. Mr. Butlin thinks that a parosteal sarcoma is much less malignant than a subperiosteal tumor of the same nature, and he regards the attempt to save the member in such cases as certainly advisable.

ADONIS VERNALIS AS A HEART-TONIC AND DIURETIC.—This plant has been for a long time in use in Southern Russia as a popular remedy in the treatment of dropsy, but has not hitherto been submitted to scientific investigations made with a view to determine its physiological and therapeutical action. Professor Botkin has recently employed it extensively in his clinic at St. Petersburg, and Dr. Bubnoff presents a report of the results obtained (*Allgemeine Medicinische Central-Zeitung*, July 28, 1883). It was found to be of value in those cases of dropsy only in which there was pre-existing cardiac disease. After the administration of adonis vernalis the heart-beats were much strengthened, the size of the organ was diminished, and its tones were much louder. The systolic murmur of aortic stenosis especially was intensified. The heart's rhythm became more regular, and the pulse slower and fuller. The daily excretion of urine was increased largely, sometimes rising from ten or twelve ounces to eighty or ninety ounces in the twenty-four hours. In cases in which there was no actual lesion of the kidneys the albumen and casts disappeared. The subsidence of œdema went hand-in-hand with the increase in the amount of urine excreted, and at the same time the secondary symptoms depending upon œdema of various organs disappeared. The patients expressed themselves as feeling much better. The remedy was given in an infusion of the strength of 3j. to 3vj., to which two drops of oil of peppermint were added. The dose of this infusion was a tablespoonful every two hours.

A DYNAMIC THEORY OF CHOLERA.—Dr. John Chapman writes to the *Journal de Médecine de Paris*, of August 25, 1883, giving his views concerning the nature and treatment of cholera. He regards the disease as consisting essentially in hyperæmia of the spinal cord and sympathetic nervous system, upon which condition depend all the phenomena observed prior to the stage of reaction. His treatment consists in the application of heat to the entire surface of the body, while at the same time an ice-bag is applied along the spinal column. This application is continued as long as the symptoms of the algid stage (vomiting, intestinal discharges, and cramps) persist. The reaction sometimes becomes excessive, and then it is necessary to remove the ice-bags and apply heat to a part or the whole of the spine. He had an

opportunity, during the cholera epidemic in Southampton in 1865, to test his method in several cases of more than average severity, and claims to have met with more than the average success. He advances the following conclusions as embodying his convictions: 1. Although in exceptional cases cholera may present itself associated with blood-poisoning, it is not, as a rule, the result of this poisoning. 2. No proof has ever been forthcoming of the existence of a cholera poison, and there are strong reasons for believing that it exists only in the imagination of certain pathologists. 3. The existence of the so-called "cholera germs" is equally hypothetical. 4. Cholera does not travel from country to country. 5. The disease is produced *de novo* wherever certain determining conditions exist. 6. There are the strongest reasons for believing that cholera is neither infectious nor contagious. (The author admits, however, that the influence exciting the disease, in the centres of a cholera epidemic, may be felt by those who are not actually attacked. And, furthermore, since this influence renders all those within its sphere susceptible, the emanations from cholera patients, as well as all other impure and unhealthy emanations, may act as exciting causes.) 7. International regulations, by means of which various governments endeavor to resist the invasion of cholera, are of no avail; while the development and continuation of the disease are, in all probability, often favored by the restraint imposed by useless, and consequently unjustifiable, quarantine laws. 8. Although the exciting causes of the scourge are numerous and varied, cholera is essentially, invariably, and exclusively a phenomenon dependent upon abnormal excitation of the nervous system. 9. The chief element of a rational treatment of cholera consists in exercising a powerful and essentially sedative influence at once upon the sympathetic nervous centres and the spinal cord.

CHLOROFORM INTERNALLY ADMINISTERED.—This anæsthetic has enjoyed some repute of late in France as a remedy for the relief of pain when internally administered. It is prepared for this purpose in the following way: A flask is about three-fourths filled with distilled water and an indefinite quantity of chloroform added. It is then thoroughly shaken at frequent intervals for about an hour and then set aside. When the upper part of the mixture becomes perfectly clear it is decanted from the cloudy deposit formed by the excess of chloroform at the bottom. This "water of chloroform" is of the strength of about nine parts per thousand. Diluted with an equal amount of distilled water it has a most happy effect in the pain or nausea attending the process of digestion in dilatation of the stomach. Dr. de Beurmann recommends it also in pain accompanying organic disease of the stomach, in nervous vomiting, and in the vomiting of pregnancy. It is of rather agreeable flavor, and may be advantageously employed in combination with orange-water as a vehicle for the solution of chloral and other hypnotics, and also of salicylate of soda. At ordinary temperatures it is a stable preparation, and uninfluenced by the action of light.—*La France Médicale*, August 28, 1883.

TREATMENT OF CROUP BY SULPHIDE OF CALCIUM.—In a communication read before the Medical Society of Rheims (*Union Médicale du Nord-Est*, August 15, 1883), Dr. Meunier reported upon a number of cases of croup treated by sulphide of calcium in doses of three to four and one-half grains per diem. The remedy was given in granules of one-tenth of a grain each, one or two granules every hour. The author regards the sulphides as of great value in the treatment of diphtheria and croup, while not being, strictly speaking, antidotal to the specific poison of this disease. Their mode of elimination, in great part by the pulmonary mucous membrane, is a further recommendation for their use. Dr. Meunier's success in the cases recorded was not startling, yet was such as to warrant further trial of the sulphide of calcium in this disease.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, October 6, 1883.

IDIOPATHIC ANÆMIA OF ADDISON.

It is now almost thirty years since Addison first described idiopathic anæmia, or, as it has been called since the appearance of Biermer's paper, in 1871, progressive pernicious anæmia. Even at that time, with only one case, its clinical characteristics, its course, termination, and *post-mortem* appearances were so accurately described that we may accept his description as true to the life to-day. True, up to the time of Addison's description (1855) seven cases of an unknown and undiagnosed disease had been partially described, but it is to the great physician of Guy's that we are indebted for much that we know of its clinical history.

A most interesting and instructive paper on this subject now appears in "Guy's Hospital Reports" (vol. xli., 1883), by Dr. P. H. Pye-Smith, in which he gives the complete clinical history of a case coming under his care at the hospital, with tables of all recorded cases up to the time of the writing. The case reported by Dr. Pye-Smith lived almost a year after entering the hospital. The patient, a male, had noticed an alteration in his complexion about a year before that time, and almost at the same time his skin became covered by little blisters, similar to those produced by stinging-nettles, which produced itching and stinging. Dyspeptic attacks, to which he had been subject, became more frequent, and soon the well-known symptoms of the disease became well marked. These, as is well known, are a pallid, yellowish skin—warm, moist, and soft, with the veins showing clearly through it on the extremities; white, pearly conjunctiva; pale, sodden, flabby tongue; great paleness of the oral and buccal mucous membrane; breathlessness on exertion; cardiac murmurs, generally systolic, bruits being also heard over the axillary, carotid, femoral, and subclavian arteries, sometimes over smaller vessels, and, as a rule, a *bruit de diable* is heard over the cervical region. Hemorrhages into the retina, though sometimes found, are not constant. When they do occur they are usually very small, and very numerous. The pulse is rapid at the onset, not unfrequently dicrotic, full in the early stages, collapsing, and compressible; and the temperature one or two degrees above normal, though when death is imminent it may sink to 95° Fahr.

The examination of the blood, however, furnishes, we may say, the most important clinical symptom. The hæmal unit is markedly decreased, as was well shown in the case reported, in which it was 38.4, being only a

little more than one-third of the normal. This proportion gradually, in some cases rapidly, decreases. The blood has a pale, thin, watery appearance, and is very transparent; the coloring matter being reduced in some cases to only twenty-five per cent. of normal, and the proportion of red corpuscles may fall below one-eighth, and when examined they are seen to have lost their spherical shape in many instances, are often crenated, and the coloring matter is irregularly collected either in the middle of the corpuscle, or eccentrically, and the tendency to form rouleaux is absent. There are various other and more rare minor symptoms, such as epistaxis, vomiting, etc., and there may be anorexia, though this last is by no means general.

Some of these will be recognized as symptoms occurring in every case of anæmia. There is breathlessness on exertion because the red corpuscles—the carriers of oxygen to the tissues—are diminished; and muscular weakness affecting both the voluntary and involuntary muscles from the same cause; coldness of the feet; passive exudations; and paleness resulting from the loss or decrease of hæmoglobin, with functional murmurs in the heart and great vessels; and fatty degeneration of the organs from deprivation of nutrition. It is, however, beyond our scope at present to enter into a consideration of the various anæmiæ which may result either from loss of the normal constituents of the blood from an appreciable and known cause, or from a diminished increase of blood-forming material, or from an increased destruction of formed elements. Two affections are now recognized which are not dependent upon any of these causes, but idiopathic or pernicious anæmia, and chlorosis, though having these points in common, are so different that it is unnecessary to enter into a differential diagnosis in this place.

Dr. Pye-Smith conveniently classifies anæmia under three heads: 1, Those cases which are secondary and symptomatic; 2, cases associated with diseases of the cystogenic organs, whether or not lucæmic; and 3, idiopathic, primary, or essential anæmia without any symptoms during life, and without any lesions after death which cannot be explained as directly due to anæmia. From the first group of cases idiopathic anæmia is distinguished by its severity, malignant character, retinal and other ecchymoses, and by the increased temperature and almost invariably fatal result; and from the second by the absence of lucæmia, the structural changes in the red corpuscles, and the absence of any especial enlargement of the spleen, or lymph-glands. Though our knowledge of the pathology of idiopathic anæmia is not sufficient to enable us to explain it, we believe that we are authorized in holding that it depends upon a too rapid and extensive destruction of red blood-corpuscles. Certain it is, that we have the evidence of this destruction and increase of pigment in the deep color of the urine, in the yellow tint of the skin, and in the saturated tint of the fat and muscles, the occasional pigmentation of the serous membranes, and possibly, also, in the excess of iron sometimes detected in the viscera, which it is suggested may be derived from broken-down hæmoglobin; it is possible, however, that it may be due to the ingestion of iron as medicine.

Age, sex, and occupation seem to be of but little

moment in the etiology of this affection; it is rather more frequent in earlier adult life, seems to be about equally common in males and females, and is probably more frequently seen in the lower classes, and outside of large cities. The fact that it sometimes comes on without any assignable cause, not only renders its etiology and pathology obscure, but makes it doubtful whether the sometimes detailed states, as dyspepsia, pregnancy, privation, and various discharges, are to be regarded as more than coincidences, though Coupland, in thirty-one cases, assigns pregnancy and the puerperal state as the cause in twenty cases, and the remaining eleven to privation.

As before stated, the evidence furnished by an examination of the blood is especially valuable. As regards the white corpuscles, they are, as stated by Wilks so early as 1857, not materially increased. Occasionally they may seem to be present in larger than normal quantity, but this is only due to a transient leucocytosis, and in several cases the number has seemed even to be diminished. The red corpuscles, however, may be enormously decreased—are always, in fact, much below normal, and are pale. The pale, watery condition of the blood, therefore, is due not only to the diminished number of red corpuscles, but probably also to a seeming deficiency of hæmoglobin. As regards this point there seems to be a difference of opinion. Dr. F. Willcox states (*Practitioner*, August, 1883) that the hæmoglobin value is largely increased, and Hayem found in one case that though the color of the blood was diminished from a normal of one hundred to ten, the number of corpuscles was only about one-tenth, so that there was no diminution of hæmoglobin in each corpuscle. The size of the red blood-disks is, however, largely increased, as stated by Eichhorst, Kohler, and Willcox, sometimes being so high as 9 mm. and even 12 mm. This is a valuable point in the diagnosis between idiopathic anæmia and chlorosis, if it be a constant condition, for although a few giant disks are seen in chlorotic blood, the average size is markedly diminished. In making the diagnosis, then, of idiopathic anæmia we cannot do better than quote Dr. Pye-Smith, who gives its characters as: 1, Absence of organic disease and of any recognized and sufficient cause of anæmia; 2, absence of uterine and ovarian complications; 3, severe and ingravescent anæmia; 4, irregular and occasional pyrexia; 5, retinal hemorrhage; 6, diminution of red blood-disks without lucæmia, and presence of small, deeply colored, red corpuscles; 7, maintenance of adipose tissue.

The treatment of pernicious anæmia, though by no means gratifying, or as yet well determined, is not entirely futile, for cases do recover. Pye-Smith records twenty recoveries out of one hundred and thirty collected cases. *Imprimis*, it may be stated that iron is of no value in these cases. Though it is a necessary constituent of the blood-coloring matter, it cannot increase the number of the corpuscles, and in this disease we have reason for asserting that the addition of younger red corpuscles is almost entirely suspended. According to Willcox, it seems that iron not only does no good, but is actually harmful by irritating the stomach and causing vomiting. In this form of anæmia we must, at present, accept one of two theories; either that the power of corpuscle

formation is suspended, or almost entirely abolished; or that the young corpuscles, if formed, have little or no power to absorb hæmoglobin, and consequently do not reach their full development, and the concentration of the coloring matter in a few large corpuscles, as claimed by Willcox, may be due to a compensatory process by which oxygenation of the tissues may still be carried on, even with the great numerical reduction of the corpuscles. The end and aim of all treatment in these cases is to increase the number of corpuscles, and since the administration of iron cannot accomplish this, theoretical and clinical reasons are against it. Arsenic, however, may and does, in many cases, produce not only an increased number of red corpuscles, but improves the general symptoms. Though, as a matter of course, we cannot suppose that iron is a specific for the disease, some excellent results have been obtained by its administration. This and transfusion, with careful diet, seem to offer the only hope for the subjects of idiopathic anæmia. Quincke recommends transfusion into the radial artery, but we do not see that arterial transfusion is at present to be preferred, except that there is less danger of introducing air than when a vein is opened. Five cases have had recovery follow transfusion, and arsenic has given still better results, though oftener used.

THE MIDWIFE AND HER RELATION TO THE PHYSICIAN.

THE recent efforts made to legalize a State Board of Examiners for the medical schools, together with the prompt recognition and suppression by the County Medical Society of quackery in this city, has awakened an interest in medical education and legislation that bids fair to elevate the professional standard.

Coincident with this a movement is rapidly spreading among the larger cities throughout the country for the employment of intelligent women as nurses for the sick and to attend women in labor. It may be traced in part to the growing demand for opening a new field and offering women of the better classes increased facilities for self-support, but chiefly to recent advances in medical and surgical practice, which require nicer care and closer observation of the sick than untrained helpers can give. To supply these needs, "training schools" for nurses have been established in connection with certain of the larger general hospitals; while in this city a "College of Midwifery" has been recently organized.

The author of this paper desires to call the attention of the profession to this matter, so that the proper relation of the midwife to the physician may be determined. The time has come when the profession must concede to the midwife a legitimate place in the community. A writer, in the *New York Medical Journal* of April 14th, of an editorial on this subject, says: "With the continued immigration constantly going on, there are now thousands of poor women who, if compelled to make the choice between the attendance of a medical practitioner and a resort to some public charity, would find themselves under the necessity of adopting the latter expedient. Most of the midwives in the United States are of foreign birth and training, if they can be said to have been trained at all, and their ways do not commend them to people of American birth. Hence many a woman that could have

afforded her services has shrunk from the experiment and become a burden on the community. With proper facilities for their education, and special legislation to protect them, there is no reason why a class of intelligent, well-educated American midwives should not arise amongst us. The result of such a change cannot but prove conducive to the welfare of all concerned. Members of the profession who, for one reason or another, practise obstetrics for fees utterly out of proportion to the value of the services rendered, will not suffer to any great extent by the establishment of a class of trained midwives; for the latter will draw their support rather from those who now pay no fee at all than from those who are able to employ even the humblest practitioner of medicine." That the writer's views are correct no one will deny; for further confirmation we can turn to France or Germany, where the midwife is as essential in the community as the curate, the lawyer, and the doctor. Her importance has been recognized, and, in order that her calling may be protected against the invasion of unqualified women, the State erects a legal barrier in the shape of a strict examination. If midwives in the United States were what they should be, or what they are compelled to be in Germany, there would be no need of any special legislative enactment; but unfortunately they are not. They are as a rule ignorant, and, worse than all, their ignorance is fearless; the evil done by their malpractice is beyond comprehension. Any physician who makes a speciality of obstetrics and diseases of women, and even one whose practice is not extensive in this direction, will be able to relate many cases where, through the brutish ignorance and stupidity of some midwife, a woman or her child, perhaps both, have died, to say nothing of the many uterine diseases traceable to her mismanagement.

Recognizing these facts, it is time that the profession should make some effort to elevate the midwife to her proper position in the community. It is not necessary to lay open the entire field of obstetrics to the midwife. On the contrary, her practice should be strictly limited; the knowledge imparted serving to indicate to her not only how to manage a normal labor, but above all when to send for a physician, and what to do pending his arrival.

Thus instructed, with proper legislation to protect the people from incompetency, the midwife's relation to the physician would be established, and her position in the community made useful and necessary.

AN INSIDE VIEW OF A COUNTY MEDICAL SOCIETY.

We have received from a correspondent in Pittsburgh, Pa., a letter giving a very dolorous account of the state of medical affairs in that city. We are unfortunately compelled to believe that the recital is very little exaggerated. The Allegheny County Medical Society is, we are told, in regular affiliation with the State and national associations, yet it contains many members who do most questionable acts, still professing adherence to the Code.

Says our correspondent: "One of our 'popular' members advertised for a year in the daily press that he had resumed the practice of his profession, while some physicians were not aware that he had ever quit it voluntarily. And again for the past year he has been advertising as giving 'special attention to diseases of the eye,

ear, nose, and throat.' Another member, who has been abroad, upon his return requested the press to announce the fact with certain additions as a matter of news.

"For several months an advertisement of two lines has met my eye, to the effect that a physician, who has been abroad, has reopened his office. And I am told that one of our specialists, who has a private hospital, has been so unsuccessful in his operations as to have acquired for it the name of 'Pittsburgh Abattoir,' in spite of all his self-laudation.

"As to boasting of cures and remedies, a thing proscribed by the Code, it is far too common to hear members of our society not alone boast, but even intimate that they 'know it all,' and that other physicians are unfit to treat certain cases.

"Certain of our members keep selected formulæ at favored drug stores, and write for 'my mixture,' etc., and, it is reasonable to think, exact percentages of those druggists. In one instance, a pharmacist informed me that having received a prescription for 'my application No. 1,' called upon the doctor (who has held many offices in the society) to find out what 'No. 1' meant, and was impolitely told that 'if he didn't know, he'd better take it to —, who did know.'

"Some old physicians attend families by the year, at ten dollars per head—a practice most unjust to young physicians, undignified and abominable. There are in our society 'no-diploma fellows' and eclectics. One member, I am reliably informed, practises 'both systems,' regular and homœopathic. And others examine in lunacy cases on the same commission with homœopaths, sign the same certificate, and justify themselves by saying, 'That's all right; it's not a consultation.' But it is professional association.

"I tell you truly, sir, there are quacks in our county society, and the thin veil of the Code cannot shield them. But since the death of the revered Dr. James King, there seems to be not a man in it with stamina to point them out. And, to our disgrace be it said, many bright practitioners, desiring not the association of such men, are not members of the society; and some others who are, contemplate resigning, the only link that holds them being the fact that membership here is compulsory to membership in State and national societies. To belong to our society is no honor. In this county a code should be individual."

Our correspondent further states that a project is on foot to start a medical college in Pittsburgh, and he deplores the consequences of such an undertaking. "The Pittsburgh profession," he writes, "is now sadly overcrowded. There is not a man in this whole community affluent through the practice of medicine. And many of us have to struggle for the necessities of life. I believe that the American Medical Association, as a matter of duty to the profession, should cause to be published widely, systematically, a bulletin to the effect that the profession *is* overcrowded *everywhere*, and to deter as much as possible further entrance."

The last suggestion of our correspondent reveals the earnestness of his feelings, which are shared by many struggling physicians throughout the country. This question, however, must be mainly settled by the laws of supply and demand.

THE PRESERVATION OF DEAD BODIES FOR DISSECTION AND OTHER PURPOSES.

SOME recent tests of the various methods of preserving bodies for dissection and other purposes, have been made by Surgeon-Major C. Sibthorpe, and reported in the *Indian Medical Gazette*. The experiments were carried on at the Madras Medical College during the winter session of 1882-83. At this place the thermometer in the winter season rarely falls below 63° F., and is often as high as 72° F.; hence dissection has been carried on under great difficulties. But these Mr. Sibthorpe believes he has overcome. The record of his experience is as follows:

Two bodies were injected with alcohol; one of these, fourteen hours after death, underwent putrefaction so fast that it had to be rejected; the other, injected within ten hours, was under dissection for fourteen days, but notwithstanding its being kept in a reservoir of alcohol, the muscles soon lost their color and the tissues shrivelled up.

Three bodies were injected with Wickersheimer's solution, one of these was under dissection thirty-seven days, another fifteen, and the third twenty-two. These bodies had also to be kept in an alcohol bath.

Seven bodies were treated with an injection of boracic acid and glycerine, which was prepared by boiling one ounce of the acid into twenty-four ounces of glycerine; about thirteen pints of this being used in each instance. This solution no doubt preserved the bodies to a certain extent, portions of one being twenty-six days under dissection. In two instances it did not arrest decomposition, and in most cases decomposition set in early in the internal organs.

Finally, by far the most satisfactory results were obtained by following the method first described by Mr. Howse (*Guy's Hospital Reports*, vol. xvii., p. 465).

This consists in injecting a saturated solution of arsenic followed up by the free use of glycerine, which latter Howse considers the preservative fluid, using the former for the purpose of preventing the generation of maggots and fungi.

In making the preparation the glycerine is heated to boiling-point, when it will take up a large quantity of arsenic. One pound to a quart was found sufficient.

About one quart and a half of the solution is first injected, and this injection should be made very soon after death. Then, in twenty-four hours, one or two gallons of glycerine are used to complete the process. Twenty-two bodies, embalmed by this process, continued in a good state of preservation for twenty-seven days, and might have been kept longer. No maggots or flies appeared, no decomposition took place, the muscles preserved their red color, there was but little odor, and no dissecting-wounds occurred. Mr. Sibthorpe believes that by this method dissecting can now be carried on as easily and comfortably in warm as in cold climates. The knowledge of this fact will be appreciated by many of our medical colleges where late spring or early autumn sessions are held.

In this connection we may draw attention to a recent paper by Dr. J. Polak, of Warsaw, who has been studying the same subject. Dr. Polak used first injections of thymol in glycerine and water, as recommended by

Virotsef, then injections of corrosive sublimate dissolved in the same substance.

He found, says the *Lancet*, in commenting on this paper, that thymol, like sublimate, when used in a sufficiently concentrated form, arrests decomposition of the whole body by simple injection of the fluid through the carotid or femoral artery, the corresponding vein being opened. But he also found that even an advanced state of decomposition of the limbs was arrested, and the signs of such decomposition disappeared under the use of injections of sublimate, especially if only spirit and glycerine and no water were used. The skin became mummified and of a dark brown color, and the muscles acquired the appearance of smoked ham under either method, and neither heat nor damp had any deteriorating effect. But a much smaller quantity of the sublimate injection than of the thymol was needed to produce these results. Moreover, the color of the skin was longer preserved, and the comparative cheapness of sublimate renders it, perhaps, preferable. Dr. Polak points out that the injecting syringes should be of glass, owing to the action of sublimate on copper. For ordinary anatomical purposes an aqueous solution—1 in 300 or 1 in 500—is amply sufficient, and is better than chloride of zinc.

A BLESSING IN DISGUISE.

WE have heard it argued in all apparent seriousness that the human race would have been better off had the medical profession never existed. It was contended that, generally speaking, the efforts of the physician are directed toward prolonging the lives of the weak, the decrepit, and the aged, and thus the race as a whole was deteriorated. Were there no physicians the weak and diseased would die, and thus be prevented from transmitting their ills to future generations. But doctors are a necessary evil, and if the hopes of those who look for the perfection of the human race rest upon the extinction of the medical profession, we fear they are doomed to disappointment. Yet they may find consolation in another quarter. *La Higiene para Todos*, of September 1, 1883, contains a notice of a small volume written by a certain Dr. Schwachkopf, upon the benefit to humanity of the cholera. The learned author proves, by the statistics of the disease during the past ten years, that cholera attacks only the weak and infirm, the rachitic, the scrofulous, and all those suffering from ills liable to be transmitted to posterity. Looking at the question from this point of view, he regards cholera as a providential agent by which the strength and vigor of the race is maintained. He therefore agrees with the English authorities, though on somewhat different grounds, in condemning quarantine, the sanitary cordon, and all measures of a like nature. Such measures, he says, are prejudicial to the good of mankind, they hinder the growth of a robust, clean, and healthy race, and in so far prepare the way for the irremediable decadence of nations. "It is to be noted," he continues, "that cholera does not remain in the countries which it visits. As soon as its work of sweeping out the feeble, the wretched, and the dirty is accomplished, it passes on. The disease is endemic in India, and to this fact is to be attributed the strength and vigor of the Hindoos in spite of the misery in which they live." These

views have been disputed by Professor Geistreich, who says that cholera does not attack the debilitated, but, on the contrary, carries off the most vigorous of the race. Notwithstanding the differences of opinion between these learned men, they both agree upon the necessity of keeping the cholera at a distance from the Fatherland. The one fears that the dread disease would carry off the three most noble ruins in Germany, the Emperor William, Von Moltke, and Bismarck; the other is equally solicitous about the safety of these three illustrious personages in the event of a cholera visitation, since he considers them the strongest and most robust individuals in the nation. Our esteemed contemporary of Barcelona wonders greatly at these very original ideas, and seems to have been completely taken in by the ponderous Teutonic joke of Dr. Softhead and Professor Strongmind.

THE INJECTION OF ETHEREAL SOLUTION OF IODOFORM IN FUNGOID SYNOVITIS.

THE treatment of chronic arthritis, and more particularly of fungoid joint disease, as at present practised is, to say the least, far from satisfactory to either patient or surgeon. If, as is by no means improbable, fungoid synovitis is but the first local expression of a commencing tuberculosis, the importance of a speedy cure is manifest, even leaving out of consideration the desirability of preserving the integrity of the joint. But to obtain a speedy cure by the methods of treatment at present in vogue is impossible. To those believing in the tubercular nature of these joint affections, their superficial seat offers great temptation to try the effect of local so-called antiseptic remedies. Many substances have been suggested as suitable for injection into the diseased joints, and some of them have been tried with alleged beneficial results. The late Professor Hueter was an enthusiastic advocate of intra-articular injections of carbolic acid, but others who have been led to adopt this method have met with but indifferent success. More recently Mikulicz has proposed the injection of a solution of one part of iodoform to six of sulphuric ether. Acting upon his suggestion, Drs. Neumann and Müller, of Karlsruhe, have treated a number of cases of fungoid joint disease by this method, with, upon the whole, rather encouraging results (*Memorabilien*, July 16, 1883). The injections were made at intervals of from four to fourteen days, a Pravaz syringe being introduced each time. They were exceedingly painful, and this was the chief objection to their use, for though there was some immediate increase of swelling it soon went down again, and an abscess was never seen to result. The treatment must, of course, be begun early in order to obtain the best results. We shall look for further trials of this method with interest, for anything that promises to expedite the tedious and exasperatingly slow cure of chronic joint disease is worthy of earnest consideration. The extremely painful nature of the procedure is certainly a serious disadvantage; but if the method is proved, on further experience, to be of real curative value, this should not militate against its use. It is probable, also, that some means will be devised to obviate this irritant action, or some other solvent of iodoform may be found to be of equal efficacy and at the same time painless.

News of the Week.

NEW YORK INFANT ASYLUM, MOUNT VERNON, N. Y.—It is reported that an epidemic of measles is prevailing at the country home of this institution, and that the mortality is unusually large, sixty deaths having occurred within three months in a household of two hundred and twenty.

YELLOW FEVER.—There were twelve deaths from yellow fever at Havana during the week ended September 22d. During the week ended September 13th there were thirteen deaths from yellow fever at Vera Cruz.

MEXICAN YELLOW FEVER.—It is proposed to establish an inland quarantine at Yuma, Arizona, to prevent the introduction of Mexican yellow fever into the United States. The fever is reported to be spreading rapidly upon the Mexican coast, in the vicinity of Guaymas.

SUICIDE OF PHYSICIANS.—Dr. S. Vander Haydon, of Winfield, L. I., committed suicide on the 15th ult., by shooting himself. Dr. Vander Haydon had recently tendered his services as surgeon to the French Government, asking for an appointment with the army at Tonquin. His application had been accepted.

Dr. R. C. Mullen, of this city, attempted on September 29th to commit suicide by cutting open the right femoral artery. In this, he failed, and he was taken to St. Vincent's Hospital. Dr. Mullen graduated from Edinburgh University in 1850, and practised in Michigan for some time. He had for several weeks shown symptoms of insanity, and had been lodging at station-houses in order to escape his imaginary foes.

ST. FRANCIS HOSPITAL, NEW YORK.—At the recent competitive examination for positions on the house-staff of St. Francis Hospital, New York, the fortunate candidates were Dr. T. Theodore Janeway and Dr. J. V. Kendall.

COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.—The opening exercises of the seventy-seventh session of this institution took place in the college building, on Monday evening, October 1, 1883, at eight o'clock. The introductory address was delivered by Professor George H. Fox, M.D.

AMERICAN ACADEMY OF MEDICINE.—The American Academy of Medicine will meet in the New York Academy of Medicine, on Tuesday, October 9th (three o'clock), and Wednesday, October 10th. The address, by Dr. H. O. Marcy, of Boston, Mass., President, will be delivered on Tuesday evening, October 9th, at eight o'clock, on "The Recent Advances of Sanitary Science; the Relations of Micro-Organisms to Disease" (illustrated by micro-photographs projected upon the screen). The following papers have been promised for the general meetings: Dr. L. S. Pilcher, of Brooklyn, N. Y., on "The Relations of Medical Journalism to Higher Medical Education in America;" Dr. Traill Green, of Easton, Pa., on "The Imperfection of Technical Studies as a Means of Mental Culture;" Dr. R. S. Sutton, of Pittsburgh, Pa., on "Cleanliness in Surgery;" Dr. Benjamin Lee, of Philadelphia, Pa., on "The Value of an Acquaintance with Botany as a Preliminary to the Study of

Medicine;" Dr. Charles McIntire, of Easton, Pa., "Is it Fair? A Study of the Comparative Political Position of the Medical Profession in the United States;" Dr. A. D. Rockwell, of New York, on "The Exact Value of the Electrolytic Method;" Dr. J. Cheston Morris, of Philadelphia, Pa., "The Milk Supply in Large Cities;" Dr. Charles E. Cadwalader, of Philadelphia, Pa., "Considerations upon the Public Provisions for the Care of the Indigent Insane;" Dr. A. D. Rockwell, of New York, "The Late Dr. George M. Beard—A Sketch." Report of the Committee on Laws of Medical Practice in the United States and Canada (Drs. Dunglison and Marcy).

FRENCH REPORTS FROM THE EGYPTIAN CHOLERA COMMISSION.—The French, at the first breaking out of cholera in Egypt, were very furious in denouncing England for having allowed the disease to be carried to Egypt from India.

Recently M. Jules Guérin announced to the Académie de Médecine that he had received reports from the Cholera Commission, in which it was stated very positively that the cholera was not brought from India but arose *de novo* in Egypt.

OBLIGATORY VACCINATION IN FRANCE.—Those interested in public health have achieved a victory in France. M. Jules Ferry, the Minister of Public Instruction, has decided that revaccination shall be made obligatory in all the colleges and lycées in France.

MEDICAL LIFE-HISTORIES.—We have already referred to the work that Mr. Francis Galton is engaged in, regarding the medical and physical history of individuals. This gentleman has recently announced in the *Fortnightly Review* a plan for obtaining from members of our profession medical genealogies having the special aim of tracing the hereditary character both of mental and bodily qualities. Mr. Galton has already tried the same plan on a large scale among eminent scientific men, with very valuable results. The points on which he wishes information are: race, conditions of life, form and feature, health and disease, vigor, sensation, artistic capacities, intellect, and character. He intends to give £500 in prizes for the best returns, and to publish the conditions of competition in October next. The competition will be open to all medical men. The results of Mr. Galton's plan will be watched with great interest.

DR. BROWN-SÉQUARD is a candidate for the seat in the Académie des Sciences made vacant by the death of M. Cloquet.

INTERNATIONAL MEDICAL CONGRESS AT AMSTERDAM.—At this meeting, held last month, a number of prominent medical men, representing Holland, England, Germany, France, and Scandinavia, were present. The propriety of holding annually an International Medical Congress to deal with hygienic questions specially affecting countries and colonies in the tropical portions of the globe was also mooted.

Sir Joseph Fayrer, whose long experience in British India enabled him to speak with the highest authority, declared that, in his opinion, the colonization of the plains of tropical countries by Europeans would never succeed. After three generations European families al-

ways died out. Even in the hilly districts of the tropics it was doubtful whether pure European blood could permanently perpetuate itself. Dr. Lewis stated that the children of English soldiers in India who were brought up in the hills from five thousand to seven thousand feet above the sea-level were always more or less unhealthy and weak in constitution, though if they were sent to Europe in time they might generally lay the foundations of robust health.

At the final general meeting, the question of the foundation of a special school for the training of physicians for the Colonies in tropical countries was discussed. The proposal of Professor Vandencorput for the establishment of an International Association to deal with the problem of epidemics was referred to the Special Committee for further inquiry, with instruction to report the result to the next Congress, which will be held in the Hague twelve months hence. The principal members of this Commission are Professors Vandencorput, De Chaumont, Lewis, Leroy, De Méricourt, and Da Silva Amado.—*Medical Press and Circular*.

THE ENGLISH CHOLERA COMMISSION.—All the members of this commission, except three, have returned to England.

Reviews and Notices.

A COMPLETE HANDBOOK OF TREATMENT. Arranged as an Alphabetical Index of Diseases to Facilitate Reference, and containing nearly One Thousand Formulae. By WILLIAM AITKEN, M.D. (Edin.), F.R.S., Professor of Pathology in the Army Medical School, Examiner in Medicine for the Military Medical Services of the Queen, etc., etc. 12mo, pp. 444. New York: Birmingham & Co. 1882.

This book is a compilation from the last edition of Dr. Aitken's well-known work on "The Science and Practice of Medicine," and comprises the chapters on treatment as written by that author. The diseases are arranged in alphabetical order, with numerous cross references, whereby the reader is enabled to turn at once to any desired subject without being obliged to refer to an index. Under each heading is found a short definition of the disease, and then follows immediately the portion on treatment. Dr. Aitken's work is too well known to require any discussion here. The book before us is printed in clear type, on good paper, and is of a convenient size for handling.

THE TREATMENT OF WOUNDS: ITS PRINCIPLES AND PRACTICE, GENERAL AND SPECIAL. By LEWIS S. PILCHER, A.M., M.D., Member of the New York Surgical Society. With One Hundred and Sixteen Wood Engravings. 8vo, pp. 391. New York: Wm. Wood & Co. 1883.

This volume, constituting the number for August in Wood's Library, well sustains the high reputation for excellence which this series of medical books enjoys. The entire subject of the treatment of wounds is discussed in a concise and practical manner, and the lucid explanations in the text are made still more clear by numerous well-executed illustrations. The first part of the work is devoted to a general consideration of wounds and their immediate effects, of the physiology of repair and the character of the influences which are capable of retarding or perverting reparative action. The subject of antiseptics is briefly considered, and the mode of application of the various antiseptic dressings is described in detail. In the second part the author treats of spe-

cial wounds and wounds of special regions, whether traumatic or produced by the knife of the surgeon. In this part the method of application of the general principles, enunciated in the preceding chapters, to particular cases is described. In addition to the table of contents there is a very complete alphabetical index, by which the reader is enabled to refer readily to any subject. The work is eminently practical and thoroughly up with the times, all the latest methods of treatment of assured value being treated of in sufficient detail. Especially is this the case in the chapters on antiseptic treatment, a department in which the German surgeons have been notably active. Here we find collected all the most recent modifications as proposed by different operators, an acquaintance with which was previously to be obtained only by a laborious search through the periodical literature. We cannot but congratulate the readers of the library on securing so valuable a work as this, which in itself is worth a large part of the annual subscription to the series.

THE PRINCIPLES AND PRACTICE OF SURGERY, being a Treatise on Surgical Diseases and Injuries. By D. HAYES AGNEW, M.D., LL.D., Professor of Surgery in the Medical Department of the University of Pennsylvania. Vol. iii., 8vo, pp. 784. Philadelphia: J. B. Lippincott & Co. 1883.

This third volume completes Agnew's Surgery. It is five years ago since the author commenced his task. During that period he has not been idle in his leisure moments. It has evidently been a pleasure to him to write, considering the faithful and earnest manner in which he has striven to get the results of his surgical experience. The work, as a whole, is quite voluminous. While on general principles we might wish it were less so, he has nevertheless given us an interesting, instructive, and exhaustive treatise. We would not undertake to say how he could curtail it, except, perhaps, regarding one or two special subjects. But even these are so admirably presented that we are forced to refrain from criticism. General surgery is supposed to include everything in the shape of operative treatment of every part of the body, and in a comprehensive treatise like the one before us it would probably be a disappointment to many surgeons if the entire range of subjects were not discussed. The author is always practical, and from such a point of view we cannot read too much of him. Besides, he infuses an individuality in his work which is highly commendable. Weighing everything according to the standard of his own experience, he is inclined to be positive and to the point. This gives to his whole work true originality, and makes it proportionately valuable to the student. The third volume partakes of the general character of the others, and is consequently an interesting and instructive one. Although appearing to lack system in its arrangement, we are inclined to believe that the author adopted the present plan of his last volume for the purpose of condensing within reasonable limits all the subjects not previously discussed. But the mere arrangement is of secondary importance to the subject matter. Each of the fourteen chapters is complete in itself, and this is probably all we need to expect under the circumstances. The volume commences with a discussion of the surgical diseases of the larynx and trachea, following in turn with sections on diseases and injuries of the nose and naso-pharyngeal region; diseases and injuries of the eye and appendages; diseases and injuries of the ear; malformations and deformities, including the domain of orthopedy; affections of the muscles, tendons, bursæ, and aponeuroses; surgical affections of the nerves, lymphatic system, skin, and subcutaneous connective tissue; syphilis; tumors; diseases of the mammary glands; electricity in its application to surgical therapeutics; operations for nerve-stretching; and lastly, massage.

Throughout the volume are scattered a large number

of illustrations—the majority original—of diseased conditions, surgical apparatus, and surgical instruments. As a whole these are very well drawn and present an artistic appearance. It would be in vain to even enumerate the various divisions of the different chapters, or even the different diseases described. It is much easier to ask one's self the question what is not in the book rather than what is omitted. But the author is enabled to get over so much ground by the admirable manner in which he brings out the salient points of the different diseases and their treatment. Some, for instance, are treated of in a few lines, but the reader is made to feel that this is all he needs. Other subjects are discussed at greater length, but are almost invariably accompanied with the author's idea of what should or should not be done. The rules of practice laid down are eminently safe and are founded on common-sense and large experience. Consequently this volume, with its predecessors, will be abundantly able to stand on its merits, which are of the highest order and which will place every purchaser of the set under lasting obligations to the painstaking and accomplished author. The volumes will take their place beside the most comprehensive, valuable works on surgery in our language, and withal will remain a credit to American surgery.

A PRACTICAL MANUAL OF THE DISEASES OF CHILDREN, WITH A FORMULARY. By EDWARD ELLIS, M.D., late Senior Physician to the Victoria Hospital for Sick Children; late Physician to the Samaritan Hospital for Women and Children, etc. Fourth edition, revised and enlarged. 8vo, pp. 218. New York: Berningham & Co. 1882.

This is a reprint of the latest edition of Dr. Ellis' work on the "Diseases of Children." As the book is issued at a low price great pains have been taken to economize space. The type is small, the lines are not leaded, and the chapters follow one after the other without any interval. We question whether there is any real economy in such books, for the injury done to the eyes by reading several pages of close print without any resting-places of white more than offsets the slight reduction in price which such an arrangement permits of.

THE ESSENTIALS OF BANDAGING, WITH DIRECTIONS FOR MANAGING FRACTURES AND DISLOCATIONS; FOR ADMINISTERING ETHER AND CHLOROFORM, AND FOR USING OTHER SURGICAL APPARATUS, and containing a chapter on Surgical Landmarks. Illustrated by 136 engravings on wood. By BERKELEY HILL, M.B. Lond., F.R.C.S., etc., etc. Fifth Edition. Enlarged and Revised. 8vo, pp. xiii., 341. New York: J. H. Vail & Co. 1883.

A work which has so pleased the public as to reach a fifth edition may be said to have passed almost beyond the reach of the critic's pen. Besides the essentials of bandaging, additions have been made which now make Mr. Berkeley Hill's book somewhat of a *rade mecum* for the surgical dispensary and surgeon's office. Among the additions to the fifth edition may be mentioned descriptions of laryngoscopy and ophthalmoscopy, accounts of Thomas' splints, Croft's plaster splints, Carr's splints, and various other improvements in practical surgery which cannot fail to be of value to the student.

The explanations of the various bandages and the methods of applying them, illustrated by clear and well-made cuts, the succinct account and rules for the treatment of fractures and dislocations, and the clear description of the surgical landmarks of the body and the useful appendix giving directions for the treatment of hare-lip, cleft palate, tapping, operations for hernia, vesico-vaginal fistula, and various other operations, make the book the most useful work of its kind for the student and country practitioner of which we have any knowledge, while it will prove a valuable addition to the library of the city surgeon.

Reports of Societies.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, September 24, 1883.

DAVID WEBSTER, M.D., PRESIDENT, IN THE CHAIR.

DR. R. E. SWINBURNE read a paper (see page 373) on

ADENOID VEGETATIONS OF THE PHARYNGEAL VAULT AND THEIR RELATION TO MIDDLE-EAR DISEASE.

DR. JOHN P. GARRISH thought that here, as elsewhere, medical men frequently overlooked general symptoms and treated the throat and nose as though these were independent portions of the body. A frequent local and exciting cause of these troubles in persons predisposed to catarrhal inflammations was smoking cigarettes. The method of treatment which had given him the best results was constitutional, consisting in the use of cod-liver oil, the syrup of the iodide of iron, and iodide of potassium, with attention to the general condition, aided by syringing with some mild astringent or mucilaginous preparation. He had obtained good results from the occasional introduction of a bougie and producing a certain amount of pressure upon the parts affected.

DR. F. H. BOSWORTH said that the more he saw of throat disease, the more he was convinced the proper treatment was not in the use of gargles, or sprays, or washes, but in the employment of such measures as remove the organic changes which are the cause of it. In every case there is organic change in some portion of the upper air-passages which is the source of the entire trouble, and he had operated with far more satisfactory results here than in any other part of the respiratory tract. He had not used the forceps. He had had some very bad results from the use of the forceps. He believed that in the wire snare we have a much more ready and effectual means than in the forceps. Certainly the use of the snare is not necessarily painful, and he never had been obliged to give an anæsthetic, except in very small children. With regard to the galvano-cautery, he had used it in several cases, and his experience differed from that of Dr. Swinburne, who says that its use is not attended by unpleasant results. On the contrary, Dr. B. knew of no instrument more dangerous in the nose than the galvano-cautery; but that it could be used without unnecessarily burning tissues, Dr. B. believed there was no doubt. Certainly its use in the anterior nasal cavity caused pain, and he thought it could not be used at all without creating intense inflammatory reaction.

DR. H. H. CURTIS said he had removed these growths with the forceps, the galvano-cautery, and the finger-nail, and after each of these methods he had seen intense depression follow, like that which occurs not infrequently after amputation of the uvula. For the removal of the flat growths which cannot be removed by the wire snare he resorted to repeated scarifications and spraying the surface with a saturated solution of iodoform in ether. To this he added constitutional treatment, especially iodide of potassium in small doses, sometimes mercurials, and with these measures had obtained his most satisfactory results.

DR. O. D. POMEROY thought that a little too much had been made of these growths since Meyer wrote an article concerning them about ten years ago. They are nothing more than enlarged glands, in nearly all cases the enlargement being due to inflammatory hypertrophy or proliferation. It is not necessary to always remove them, for, like the faucial tonsil, they usually disappear when adult life is reached. So if the existing catarrhal condition can be removed by ordinary treatment by the use of spray, which he still continued to have faith in,

he would not remove these growths. Of course, if they became so large as to act like foreign bodies and obstruct nasal respiration, they should be removed.

Occasionally these growths encroach upon the Eustachian tube, and he believed that they are a prolific source of ear trouble. Meyer had referred to one interesting fact, namely, that he succeeded in picking out twenty cases among two thousand school children in which he inferred, from a peculiarly sad facial expression and nasal tones, that there were adenoid vegetations in the vault of the pharynx. When these symptoms present themselves there is no question about the propriety of removing the growths. Whenever they obstruct respiration certainly they should be removed. With regard to the method of removal, he felt a strong prejudice against the galvano-cautery, and it seemed to him that the Jarvis snare was the most efficient means we have. He had not found it necessary to give ether if the child is a large one. Dr. Pomeroy thought the weight of testimony was against removing the growths entirely at one sitting. The reaction is sometimes serious in character, and violent inflammation is often developed, which may extend through the Eustachian tube and produce severe otitis media. Care should be exercised, when removing these growths situated near the Eustachian tube, lest too much tissue be taken away, and a cicatrix form that may obstruct the entrance to this canal. He had used the nitrate of silver probe with good results, but by this method would not remove more than one growth at a time.

DR. O. B. DOUGLAS said that if others could use Dr. Swinburne's instrument as satisfactorily as had the inventor, it certainly would be a boon to the surgeon who attempted the removal of these growths. He wished to direct attention to the reflex disturbances produced by adenoid vegetations in the vault of the pharynx, and related a case in which the entire trouble produced by them was referred to the larynx, and when the growths in the post-nasal region were removed all the symptoms disappeared, and the voice was restored entirely. He thought he might differ, perhaps, with the author of the paper concerning the desirability of removing all the growths at once. At least his experience had been that too much inflammation follows such an operation, and therefore he believed it to be desirable to remove only a portion at one operation.

DR. BOSWORTH wished to protest in the strongest manner possible against the heterodox opinion expressed by Dr. Pomeroy when he says that unless ear trouble is present these growths may be allowed to remain. He wished to say that if these growths are let alone the children will have ear trouble, and that it is a most dangerous condition to allow to remain in a young person. Undoubtedly they will shrivel up, but shall we wait ten or fifteen years for this to occur, while during this time perhaps lasting injury may be done by them? He said, No.

DR. POMEROY said he thought he put in a proviso that if the catarrh is manageable, and the growths are not troublesome, they may be allowed to remain.

DR. BOSWORTH thought that a slight condition of this kind might produce incurable mischief.

DR. HOLCOMBE referred to the former practice of removing tonsils, whereas now only a very few are removed, and the change had been brought about by the observation that hypertrophy of the tonsils can be removed by local applications, and also that there is a tendency for it to disappear of itself after a while. This had led him to conclude that many of these adenoid growths can be removed by local applications, and he had used successfully for that purpose the carbolate of iron, injections of acetic acid into the body of the growths, etc. He accepted this method in preference to excision by any means.

DR. SWINBURNE said, concerning the reaction following the use of the galvano-cautery, that while he did not think it could be used anywhere in the respiratory pas-

sages without producing such reaction, yet inflammatory reaction which had terminated in any serious trouble he had not seen. He thought the forceps was not regarded as the best means of removing these growths *unless the palate can be controlled*; but with the palate, the mouth, and the patient controlled, the entire growth can be easily removed, and at once, with the forceps and without injuring the other parts at all, and he had not seen serious inflammatory reaction follow. The serious inflammatory reaction which others had seen after removal of these growths he believed was due to the method employed, or the manner of employing it, and he thought the objection to their removal at one sitting had no real foundation. He believed that every case should be operated upon, because of the liability to the occurrence of inflammation of the middle ear, caused undoubtedly by the presence of these growths. He believed that not only the ear, but the general health is endangered on account of being obliged to breathe through the mouth. While these growths, if left to nature, will atrophy more or less, perhaps in many cases disappear, yet they have been seen in patients fifty years of age. He had employed general treatment alone, but had not succeeded in curing his patients without resorting to local measures.

Dr. O. B. DOUGLAS exhibited

A NEW HYPODERMIC SYRINGE,

made by Reynders & Co., and so arranged that it can be carried in the pocket with the facility and safety of an ordinary pocket-knife.

The Society then adjourned.

TRI-STATE MEDICAL SOCIETY OF INDIANA, KENTUCKY, AND ILLINOIS.

Ninth Annual Meeting, held in Indianapolis, Ind., September 18, 19, and 20, 1883.

(Special Report for THE MEDICAL RECORD.)

The Society met in English's Hall and was called to order by Dr. J. L. THOMPSON, Chairman of the Committee on Programme. A prayer was offered and was followed by an eloquent address by His Excellency, ALBERT G. PORTER, Governor of Indiana.

Dr. Thompson then introduced the President, Dr. WILLIAM PORTER, of St. Louis, who said that the best reply to the Governor's eloquent address and to the salutation of welcome by the morning press was the three days' work.

THE REPORTS OF OFFICERS AND COMMITTEES

were then heard and accepted. Letters from abroad were then read by the Secretary: one from Dr. SAMUEL GROSS, emphasizing

THE IMPORTANCE OF THE TRAINING OF NURSES FOR TOWNS AND RURAL DISTRICTS,

and one from Dr. L. J. JONES, informing the Convention of the presence of the distinguished military surgeon, Sir William MacCormac, at Niagara Falls. Whereupon an invitation was sent the latter by the meeting, requesting the honor of his presence at the Tri-State Convention.

A CABLEGRAM,

conveying greetings to the Society from Dr. McKENZIE, of London, who was present at its last annual meeting, was received.

THE PRESIDENT'S ADDRESS

was deferred to the first evening session. It was replete with practical suggestions in relation to the future prosperous growth of the Society and inquired what better superstructure could be built upon the Tri-State as its foundation walls than the Great Western Medical Association. The address was referred to a committee, who, upon submitting its report, recommended a change of name and an enlargement of the Association's territory.

The name suggested by the committee and finally adopted by the Association was

THE MEDICAL SOCIETY OF THE MISSISSIPPI VALLEY.

The name will afford to every mind, American or European, a definiteness of geographical location and territory comprised within the boundaries of the Association.

The territorial limits are marked by great natural boundaries, the Alleghenies and Rockies, the Gulf and the Great Lakes.

THE MANNER OF THE ELECTION OF OFFICERS OF THE ASSOCIATION

was a subject that came up for discussion. Instead of the present incumbents appointing their successors, it was determined that the several members of each State represented should appoint one member to serve upon a committee for the election of officers.

THE OFFICERS ELECTED FOR THE ENSUING YEAR

are as follows: *President*—Dr. B. N. Griffith, of Springfield, Ill.; *Vice-Presidents*—Dr. J. W. Matthews, of Louisville, Ky.; Dr. C. G. Commegys, of Cincinnati, O.; and Dr. J. E. Link, of Terre Haute, Ind.; *Secretary*—Dr. G. W. Burton, of Michell, Ind.; *Chairman of the Committee on Arrangements*—Dr. F. L. Matthews, of Springfield, Ill.; *Chairman of the Committee on Programme*—Dr. C. P. Pearson, of Indianapolis, Ind.

It was decided to hold

THE NEXT MEETING OF THE ASSOCIATION

at Springfield, Ill., within two weeks of the middle of September, 1884, the exact date to be given at an early day.

The names of the Committee on Publication are: Dr. G. W. Burton, of Michell, Ind.; Dr. Wm. D. Byrd, of Quincy, Ill.; and Dr. H. I. Raymond, of Indianapolis, Ind.

The programme presented fifty-three papers for reading and discussion before the Society.

TORTICOLLIS,

by Dr. D. S. BOOTH, of Sparta, Ill.

The case related was that of a boy, twelve years of age, affected with extreme wry-neck, congenital in kind, not in degree. Subcutaneous tenotomy practised upon the tendons of the sterno-cleido mastoid and trapezius, and upon the deep cervical fascia, brought about an excellent result, and transformed an ugly deformity into the beauty of symmetry.

TREATMENT OF COMPOUND FRACTURES,

by Dr. AP MORGAN VANCE, of Louisville, Ky.

Shall compound fractures be treated by the open method, by through drainage, or by occlusion? If the wound is closed can the possible formation of pus be determined before any danger has arisen to the patient? Make use of the thermometer as your guide. High temperature during the first forty-eight hours is not alarming; after the second day it betokens pus-formation. The Doctor's practice was to occlude an ordinary compound fracture, and then, if pus should form, to establish drainage.

Dr. JOSEPH EASTMAN, of Indianapolis, said: I agree with the essayist in the belief that compound fractures may often be reduced to simple fractures, but do not think we could depend upon the thermometer at all times. I think with Dr. Thomas that the three great discoveries of medical science within the last century are vaccination, anæsthesia, and the clinical thermometer. My experience corroborates that of Dr. Tait, that in prolonged shock following surgical operations or compound fractures the patient might go down to death without the thermometer hanging out the red lantern signalling danger, but I have never known an instance of profound shock where the pulse did not beat more and

more rapidly until it ceased its pulsations, or until reaction set in. If I resorted to plaster-of-Paris splint for putting up a compound fracture, I should use the Bavarian form, admitting of inspection as often as required.

NERVE-STRETCHING,

by DR. J. B. WRIGHT, of Olney, Ill.

The operation seemed peculiarly adapted to chronic cases.

DR. BYRD thought that the rationale of nerve-stretching in the cure of neuralgias might be explained by the traction made upon the vertebral end, loosening adhesions and removing thickenings, thus allowing that part of the nerve-trunk near the vertebral foramen room for expansion. He laid stress upon the therapeutic value of extreme flexion of the thigh in sciatic neuralgia.

DR. R. E. HAUGHTON, of Indianapolis, based his pathology of neuralgic pain upon impaired nutrition of the nerve, leading to molecular change in its structure.

FRACTURE OF OS FRONTIS OF EIGHTEEN YEARS' STANDING,

by DR. W. S. HAYMOND, of Indianapolis.

The case cited was that of a woman hit in the forehead with a stone. Two months afterward had pain in her head which increased in severity continually. After years of suffering, an abscess opened in the scalp, and on passing a probe into the opening of exit of the pus, the frontal bone imparted to the hand of the surgeon a sensation of roughness. A depressed fragment, rough, necrosed, and suppurating, from injury eighteen years previous to the os frontis, was removed. It consisted partly of the external and partly of the internal table, and measured two by three inches. The neuralgia subsided. The extent of injury, severity of pain, and the duration of the lesion were remarkable.

DR. HOBBS, of Knightstown, related a case in which, owing to a syphilitic necrosis, almost the entire calvarium had to be removed at successive operations.

DR. EASTMAN drew the lesson that the most desperate cases are worth our best efforts, and advocated early use of the trephine in doubtful cases of head injuries with untoward symptoms.

DR. BYRD referred to the use of the trephine in the cure of epilepsy and insanity.

DR. THOMPSON had trephined twice in epilepsy at the time of the war with good results.

DR. G. V. WOOLEN, of Indianapolis, said that Dr. Haymond's results justified the operation. In extreme cases operate. In simple depression without symptoms let it alone; when bad results come, then operate. If epilepsy, suppuration, and neuralgia supervene, then the acute symptoms have passed away and no artery will be found crushed.

DR. JOHN COMINGORE said unless the fracture be compound or comminuted, wait. Do not cut down upon a simple fracture for purpose of diagnosis. In simple fracture with slight depression, the brain may accommodate itself.

MYELITIS DUE TO ARSENICAL POISONING,

by DR. A. W. BRAYTON, of Indianapolis. Recovery after ingestion of one ounce of arsenic.

SYPHILITIC INTERSTITIAL KERATITIS,

by DR. H. M. POST, of St. Louis.

The existence of this disease was established in 1857, by Jonathan Hutchinson. The diagnosis of superficial and interstitial keratitis should be readily differentiated if we look sharply at what is before our eyes and use oblique illumination. In treatment the sheet anchor is mercury, which is also a tonic in inherited syphilis. If iritis set in as a complication, forestall adhesions by dilatation of the pupil.

DR. THOMPSON remarked that at the very inception of interstitial keratitis what resembled a miniature snowflake appeared on the membrane of Desmet. In cases

where the tension is plus, use eserine and maybe also a double iridectomy will be required. Atropia, if employed in these instances, may lead to the glaucomatous process.

DR. POST thought that the indications for atropia or eserine, as the case might be, was too fine a point to broach before an association of non-oculists.

DR. THOMPSON gave the rule: If tension is plus use eserine, if minus use atropine. Any one presuming to practise ophthalmology should be able to tell plus, minus, and normal tension.

RESECTION AND AMPUTATION: THEIR RELATIVE VALUE,

by DR. R. E. HAUGHTON. The conditions that decide between amputation and resection are the situation and function of the joint, condition of constitution, and condition and nature of the disease. The author of the paper brought forward statistics to prove that excision was seven times as fatal as amputation in early life. No excision should be made in extremes of age, nor in phthisis, in acute disease, or malignant disease of the articular surfaces. The essayist leaned toward amputation as the rule.

DR. J. E. LINK, of Terre Haute, advocated resection of the elbow-joint, even if half the shaft of the humerus had to be excised. He declared his belief that preservation of the periosteum has nothing to do with the restoration of bone, except keeping open the cavity until osteal matter forms. In successful transplantation of periosteum, medullary matter has been removed.

DR. LINK also advocated resection at the ankle-joint as preferable to amputation above. As to the knee-joint, he was not quite clear which alternative he should adopt.

DR. EASTMAN said that recent statistics show that resection at the knee-joint is much more favorable than amputation. And why should it not be so, when in amputation so much tissue and the large artery and nerves of the popliteal space have to be severed, whereas in resection, by the use of the curvilinear instead of the H incision, not even the articular arteries need be wounded. In one resection at the knee-joint he had not used a single ligature.

DR. THOMPSON remarked upon the numerous sinuses that are apt to form after resection at the knee. In his army experience amputation at the shoulder did better than resection of that joint; but army statistics, he thought, did not usually go far enough.

DR. FRENCH, of Missouri, thought that the dangers of resections had been magnified, but that due discrimination should be used in the selection of cases.

DR. BYRD counted it his misfortune to have seen so many resections in English hospitals, some for extra-articular trouble! All got well!

DR. COMINGORE leaned in favor of excision of joints at the time of the war, but thought each case must be treated upon its own merits.

DR. HAUGHTON challenged any to refute the statistics of Bryant and MacConnac given in his paper. London surgeons were becoming opposed to resections.

PHYSIOLOGY AND PATHOLOGY OF INSANITY,

by DR. N. FIELD, of Jeffersonville.

The brain was an entity. Its pathology should be simple. Take a common-sense, rational view of any case in court, and do not allow the lawyers to perplex you by their artifices.

Then followed two papers on

SOME MENTAL PROBLEMS IN QUESTIONS OF MEDICAL JURISPRUDENCE,

by DR. C. G. COMMEGYS, of Cincinnati, and

INSANITY,

by DR. HAYS, of Chicago.

Dr. Hays said the negative character of insanity (negation of sanity) should be kept in mind. No verbal definition was possible, because a negation cannot possibly be defined in positive terms. In idiots the proper treat-

ment was the education of the perceptive faculty. Original defective perceptions, *i.e.*, incompleteness of original observation, were the forerunners of dementia. In mania, monomania, and melancholia, delusion was the characteristic faculty, a delusion being a false ideational concept, not a false belief, else, in the religious world, each denomination would consider the other insane. The true criterion of insanity was the retention of a false belief, notwithstanding that sufficient evidence is afforded to show its falsity. Egotism, exalted self-consciousness, is the essence of a lunatic's mania or melancholia.

SPONGE-GRAFTING,

by DR. EDW. BORCK, of St. Louis.

Sponges to be prepared in acid and iodoform. Sponge-grafts one line in thickness, covering the wound. Infrequent removal of dressings. Care for the granulations. Useful in recent railway lacerated wounds as well as in extensive ulcerations.

STONE IN THE BLADDER,

by DR. H. H. MUDD, of St. Louis.

The aim of the paper was to determine the extent of dilatability of the bladder compatible with safety, *i.e.*, its non-rupture. Capacity is desirable for a large quantity of water in litholapaxy. The dilatability of the bladder-walls was found to be very great.

THE ANTIPYRETIC TREATMENT OF TYPHOID FEVER,

by DR. G. C. SMYTHE, of Greencastle.

Death may result from specific lesions of the disease, as intestinal hemorrhage or peritonitis from perforation. But the percentage of mortality from such causes is quite insignificant when compared with the mortality of typhoid from hyperpyrexia and the degenerations following. Excessive heat production and faulty heat elimination, one or the other factor, will be found, and should be combated by antipyretic treatment. Cold water by effusion or baths, or in some form of external application, with quinine in dose of twenty-five to fifty grains each alternate night so as to cause marked morning remissions, constituted the treatment strongly advocated in the first days of the fever.

DISEASES OF THE FALLOPIAN TUBE, WITH TAIT'S OPERATION AS A MEANS OF CURE,

by DR. THOMAS HARVEY, of Indianapolis.

Symptomatology and etiology obscure in the early stages. One of the most marked symptoms was the occurrence of intermenstrual pain, usually on a certain fixed day. Dr. Harvey was of the belief that this symptom of intermenstrual pain was caused by a stenosis of the tube or other obstruction to the passage of the ovule along the oviduct. The escape at intervals of a limpid or purulent fluid from the uterus, and the ability to pass a uterine probe into the dilated Fallopian tube afford a diagnostic symptom and sign that cannot be readily mistaken in their significance.

The author cited a case of tubal disease that had been diagnosticated by different surgeons as hip-joint disease, spinal curvature, ulcer of stomach, and hepatic colic, and the unfortunate patient had successively been cupped, bled, blistered, and made to wear a plaster-of-Paris jacket. An exploratory incision revealed ovarian disease, the ovary being brought into view through a small abdominal incision by elevating the uterus through the vagina.

Dr. Harvey sought to show that Tait's operation should not be resorted to until other means had failed to make a cure in disease of the Fallopian tubes. He had frequently injected a sixty-grain solution of silver nitrate into the dilated tube with good effects.

DR. J. R. SUTCLIFFE, of Indianapolis, related a case of death after intra-uterine injection of copperas, upon which he was called to make a post-mortem, which revealed the injected fluid in the peritoneal sac.

DR. HAYMOND related a similar case from white-oak bark injection.

DR. HARVEY declared the cause of death in such cases to be shock, and not peritonitis or septicæmia.

CHLOROFORM IN LABOR,

by DR. G. V. WOOLEN, of Indianapolis.

The indications for chloroform were found in its effects upon the nervous system, relieving pain and shock; upon the muscular system, bringing about relaxation; and upon the secretory system, stimulating the secretions. This paper was discussed at length, and brought out the following points, *viz.*, dangers of chloroform in labor, degree of anæsthesia compatible with safety, and mode of administration.

DR. HARVEY would not go beyond the second stage of anæsthesia, which sufficed to allay pain and effect relaxation. The third stage of anæsthesia arrests labor. The chloroform should be dropped upon a handkerchief by an attendant and administered by the patient herself, and that too only during a contraction.

DR. JOHN CHAMBERS, of Indianapolis, called attention to the numerous instances of death from chloroform, chronicled in the London *Lancet* during the past ten years. It was too generally the received opinion among the profession that authentic cases of death from chloroform in the lying-in chamber were exceedingly rare.

Dr. Chambers in his obstetric practice frequently employed ether, as a safer anæsthetic than chloroform, fulfilling the indications nearly as well as chloroform, and at the same time making it more difficult to plunge the patient into that state of dangerous anæsthesia, known as the third stage.

NOTES ON TRACHEOTOMY,

by DR. WILLIAM H. MYERS, of Fort Wayne, Ind.

The burden of the paper was that tracheotomy should not be regarded as a *dernier ressort*. With Trousseau, the essayist thought that it was as obligatory to perform timely tracheotomy as to tie the carotid artery when cut.

DR. EASTMAN also advocated early operation in cases of foreign body in the larynx, and related the case of a child with lodgement of a foreign body in its trachea, on whom he urged an operation before daylight, but was put off through the remonstrances of the parents, who deferred the operation till eight o'clock in the morning.

The child being raised from its bed in the morning by the nurse, the foreign body rolled into its larynx and caused fatal obstruction.

DR. L. J. JONES, of Chicago, presented a very practical paper upon

ERRORS OF REFRACTION AND DEFECTS OF ACCOMMODATION,

urging their correction and early relief by glasses prescribed by a scientific oculist and optician.

DR. WILLIAM BYRD, of Quincy, Ill., exhibited a

HUTCHINSON'S INHALER,

with which he had been using an anæsthetic compounded of bromide of ethyl, one part; chloroform, three parts; and alcohol, four parts. Had used it in 78 cases, without giving rise to vomiting, retching, or any untoward symptom; and had consumed but two and one-half pounds of the anæsthetic, the cases comprising many capital and tedious operations.

THE LAST AFTERNOON SESSION

was held in the beautifully decorated hall of the State Insane Institution, upon invitation of the superintendent, Dr. W. B. Fletcher. After the meeting a visit to the wards of the Institution was made by the members of the Society.

THE PARISIANS CONSUME ten thousand horses and four hundred mules annually. The excuse is that horse-flesh is good, cheap, and free from disease.

Correspondence.

OUR LONDON LETTER.

(From our Own Correspondent.)

THE MEDICAL HOLIDAY—HEALTH RESORTS—DEATH OF DR. BERTIER FILS—THE APPROACHING WINTER SESSION—COLD AND WARM WINTER RESORTS—STUDENTS NUMBERS—INTERNATIONAL CONGRESS OF ANTI-VACCINATIONISTS.

LONDON, September 24, 1883.

LONDON still exhibits a dearth of doctors, though it must be confessed that this statement is to be received *cum grano*; just as the more common assertion that "nobody is in town" is sometimes modified by the cynical addendum "except three and a half millions of people." These millions are all sufficiently cared for by a rather overstocked profession, and it is only the well-to-do and the consultants who have left their patients to the care of their less fortunate brethren or have followed them to their holiday resorts. Our wealthy patients are, indeed, scattered far and wide, and the majority will not return for weeks. Many of them have gone to drink the waters at the fashionable spas, and books on those "cures" are the chief representatives of medical literature. Thus Dr. Despres has issued a medical guide to Contrexéville, which is noted for its effects on the urinary organs, and, if we are to believe this local authority, may sometimes obviate the necessity of lithotripsy or the more dreaded cutting. Dr. Vintras, a French physician practising in London, has published a guide to all the spas of France, which is ably compiled and well got up. A work of much wider scope and of a more scientific nature is the "Mineral Waters of Europe," the joint introduction of Professor Tichborne, the well-known Dublin analyst, and Dr. Prosser James, of the London Hospital and the Throat Hospital. This physician also published lately a fifth edition of a small monograph on "Vichy and Its Therapeutical Resources," which first appeared nearly twenty years ago. Dr. Blanc has brought out a little book in English on "Aix-les-Bains," a most popular spa, which has just been patronized by our Princess Beatrice. Last year the younger Dr. Bertier, of Aix, published an English medical guide to this resort which was well received, and just as I was occupied with this letter comes the sad news of his untimely decease. He will be greatly missed by many English invalids who frequented Aix-les-Bains. He was a native of the place, but he spoke English fluently, and understood English medicine and English ways. After taking his degree in Paris his father, who still practises at Aix, sent him to this country to acquire our language and prolong his medical studies. He then began practise in his native town and speedily acquired a considerable position, his geniality and kindness, together with his talents, making him a favorite. This season the Princess Beatrice being sent to Aix by her advisers here for some rheumatic symptoms, was placed under poor Bertier's care. A day or two after his royal patient left he was taken ill with febrile symptoms. These soon developed into typhoid, and now I hear of his death, at the age of thirty-seven. *Sic transit gloria.*

Though our dead season is not over there are many signs that the next session is at hand. The medical schools are freely advertising their arrangements for opening on October 1st, and no doubt most of the introductory lecturers for the occasion have well advanced with the preparation of their addresses. It is a grand opportunity of speaking to the public. What a pity these gentlemen do not meet and agree together to send forth a loud, united protest against the manner in which medical legislation is burked, or an indignant remonstrance respecting professional grievances.

Another sign of the times is the appearance of books or pamphlets on winter climates. As the summer re-

sorts close those for winter open, and already people are preparing to follow the swallows, while a few are as ready to seek the quiet but cold air of high mountain valleys. The climatic treatment of consumption might have been expected to receive less attention during the war of the bacillus; but at present the fight does not penetrate far beyond professional circles, and invalids who have basked in the sunshine of Egypt or the Riviera often long for the South as soon as autumn's clouds set in.

A further notice of the coming session is forced upon medical readers by the simultaneous issue of "Students' numbers" of all the journals. Not that they seem to be valued by students, for they only consist of the "regulations" of the examining bodies and a few paragraphs of trite advice. These numbers are, in truth, mere baits for advertisers; these paid-for announcements make up the bulk of the bulkiest issue for the year, a veritable *farago libelli* as uninteresting as it is useless. Take a single item in proof of this, one of them gives students a few words about books, enumerating among those to be read on one subject more than would be found in a diligent physician's library.

International movements have invaded medical affairs, as witness the brilliant congresses at Philadelphia and London. We have also had parodies of these in the form of an "anti-vaccination congress," and the third of these strange gatherings has been summoned to be held at Berne. Many will regret to see that the fanatics of this movement have the support of Mr. Herbert Spencer. Philosophers in this nineteenth century seem curiously constituted. There will of course be an M.P. or two present, but they do not count for much. Then the ex-professor, F. W. Newman, is a supporter, but this quondam teacher of Latin has long ceased to possess any real authority, and seems to seek popularity in all sorts of unorthodox assemblies of pseudo-scientific pretensions. His book on the "Phases of Faith" attracted attention and turned not a few youths into the muddy stream of scepticism, but it was by no means scientific or even philosophical. Of course the coming "Congress" opens, not for inquiry but to advocate the prejudices of the insignificant minority who make up the "vaccino-phobiacs," as they have been called. Such an assembly may therefore vote its foregone conclusions in complete security that it cannot attract much notice from the scientific world. I see no "delegate" from America in the list which I have received. May we conclude that the people of the States are too well educated to favor the fanatics?

Army News.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from September 22 to September 29, 1883.

DE LOFFRE, A. A., Captain and Assistant Surgeon. Assigned to duty at Fort Niagara, N. Y. S. O. 182, par. 5, Department of the East, September 27, 1883.

HAVARD, VALERY, Captain and Assistant Surgeon. Assigned to temporary duty at post of San Antonio, Texas. S. O. 120, par. 10, Department of Texas, September 21, 1883.

REED, WALTER, Captain and Assistant Surgeon. Relieved from duty at Fort Omaha, Neb., and assigned to duty as Post Surgeon, Fort Sidney, Neb. S. O. 103, par. 5, Department of the Platte, September 22, 1883.

SHANNON, W. C., Captain and Assistant Surgeon. Assigned to duty at Fort Bridger, Wyoming. S. O. 102, par. 3, Department of the Platte, September 19, 1883.

APPEL, A. H., First Lieutenant and Assistant Surgeon. Assigned to temporary duty at Fort Warren, Mass. S. O. 181, par. 3, Department of the East, September 25, 1883.

CARTER, W. F., First Lieutenant and Assistant Surgeon. Assigned to temporary duty at Washington Barracks, D. C. S. O. 182, par. 5, Department of the East, September 27, 1883.

RICHARD, CHARLES, First Lieutenant and Assistant Surgeon. Relieved from further duty at Creedmoor, N. Y., to return to his proper station, Fort Adams, R. I. S. O. 180, par. 1, Department of the East, September 24, 1883.

RICHARD, CHARLES, First Lieutenant and Assistant Surgeon. Granted leave of absence for two months, with permission to apply for extension of two months. S. O. 49, par. 1, Military Division of the Atlantic, September 25, 1883.

WAKEMAN, WILLIAM J., First Lieutenant and Assistant Surgeon. Relieved from temporary duty at Fort Sidney, Neb., to rejoin his proper station at Fort D. A. Russell, Wyoming. S. O. 103, par. 5, Department of the Platte, September 22, 1883.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending October 2, 1883 :

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
<i>Cases.</i>								
September 25, 1883.....	0	84	29	7	4	17	0	0
October 2, 1883.....	0	86	26	2	11	41	0	0
<i>Deaths.</i>								
September 25, 1883.....	0	12	2	5	2	12	0	0
October 2, 1883.....	0	11	8	3	4	16	0	0

THE SOCIAL PURITY ALLIANCE.—As the college terms are now beginning and the medical student is abroad, we can print with propriety, the following interesting notice from the *Students' Journal*. Says the editor: "I have just made a discovery, which I am sure will interest many readers, which is that a society exists in connection with University College which the promoters hope will have a very important effect in extinguishing what is termed the 'Social Evil.' The society is termed the 'Social Purity Alliance,' the members of which pledge themselves, if unmarried, to abstain from the gratification of the animal passions. There is certainly, unless my observations have misled me, an extensive field for the operations of such a society as this among medical students. Many medical students act, when they enter upon hospital practice, as if the acquirement of the knowledge of good and evil was part and parcel of their professional education, and the results of their investigations are often very terrible and destructive. While wishing the 'Social Purity Alliance' success, I fear that the operations of the society will not have much effect upon the morals of medical or any other students, although the meetings of the society have been better attended than the promoters could have expected."

MEDICAL DEPARTMENT OF THE NEW YORK LIFE INSURANCE COMPANY.—Dr. Henry Tuck has been appointed Senior Medical Director of the New York Life Insurance Company, in place of Dr. Charles Wright, recently deceased. Dr. Abel Huntington has been appointed Junior Medical Director, as successor to Dr. Tuck. Dr. Buchanan Burr has been appointed Dr. Huntington's successor, as City Examiner.

THE SUMMER CORPS OF PHYSICIANS AND THEIR WORK.—From the report of Dr. E. H. Janes, Assistant Sanitary Superintendent, on the work of the summer corps, it is seen that the entire amount of work done during the two months of service is equivalent to visiting 43,915 houses, 198,932 families, and 6,601 cases of sickness. This includes not only tenement houses, but all classes of dwellings occupied by the very poor. Some visited once and others several times each. A great many of the cases treated were of a very mild type, needing but a single prescription, as is shown by the small number of deaths occurring, 28 in all, of which 10 were of cholera infantum, 4 of diarrhoea, 1 of dysentery, 2 of gastro-enteritis, 2 of diphtheria, 1 of scarlet fever, 5 of measles, 2 of phthisis, and 1 of marasmus. Besides caring for the sick, they distributed 17,542 circulars containing brief instructions on the care and feeding of infants, and the management of sun-stroke, and 3,293 free excursion tickets for the floating hospital of St. John's Guild. These excursions are regarded as an excellent auxiliary to the efforts of the Board of Health.

IMPURITIES AND ORGANISMS IN THE AIR OF THE COMPRESSED-AIR CHAMBER.—Dr. J. Solis Cohen, of Philadelphia, writes: "THE RECORD of September 22d has an abstract, p. 335, on 'Impurities and Organisms in the Air of the Compressed Air-Chamber.' The writer seems to have overlooked the fact that sterilization of the air for the condenser must be superfluous so long as the air remains unsterilized in the consulting-room, in the patient's apartments, and everywhere else where he breathes."

TARDY ACTION OF PILOCARPIN?—Dr. F. W. Ellis, of New Richmond, Wis., writes, that on January 10th he gave a boy, aged three years, suffering from ascites, a course of pilocarpin, covering two days. From the 11th to the 16th there was no effect. On the night of the 16th a fly-blister was applied. On the 17th all the characteristic symptoms of jaborandi appeared; profuse sweating and salivation, so that the circumference of the abdomen diminished two inches.

A CASE OF CONGENITAL AND HEREDITARY GOITRE.—Dr. G. S. Chalmers, of Alton, Ill., sends us the following unique history. He writes: "A few days ago I was called to a lady in labor and in due course she was delivered of a large boy. There was nothing remarkable in the progress of delivery, except that when labor had progressed well into the last stage, things almost stood still with the head firmly wedged in the lower strait. Imagine my surprise to see a well-developed goitre on the child's neck. The swelling came clean up under the lobes of the ears and with quite an enlargement over the windpipe. The enlargement felt moderately firm, as if from simple enlargement. The child seemed cyanotic at first, and had to be encouraged by cold water dashes and manipulation before it commenced breathing. And then it was fully an hour before the color got natural. As the cord beat quite actively I did not cut it for fifteen minutes. After this we soon found that if the head was kept fully extended breathing progressed naturally, but if the head became flexed, breathing became irregular, and the face cyanotic. It is now doing well, six days after delivery, and is a vigorous feeder. The mother is exophthalmic with quite an enlarged neck, and noticeably prominent eyeballs. I have never seen a case recorded of congenital goitre. What can be done for a case like this?"

THE LATE DR. BEVERLY LIVINGSTON, OF NEW YORK.—Whereas, The Medical Board of the Nursery and Child's Hospital, receives with deep sorrow the announcement of the death of Dr. Beverly Livingston, at the beginning of what promised to be an association of unusual usefulness to the institution;

Resolved, That we, his associates, hold in greatest esteem our remembrance of the life and character of our

friend, and desire to record our appreciation of his high attainments and skill as a physician, coming as they did from an ardent devotion to his selected life work, and our knowledge of his noble and elevated mind, and of his generous companionship.

Resolved, That we see in the melancholy event of his death that our institution, the profession, and the community are deprived of the influence and example of a pure, true, and earnest life.

Resolved, That we tender to the family of our late associate our heartfelt sympathy in their great bereavement; and that these resolutions be published in the medical journals of the city.

GEORGE G. WHELOCK, M.D.,

EDWARD L. PARTRIDGE, M.D.,

Committee.

THE RELATION OF DIPHTHERIA TO CONTAMINATED DRINKING-WATER.—Richard Cole Newton, Assistant Surgeon, United States Army, writes: "*The Sanitary Engineer*, for July 26, 1883, contains the following paragraph (page 177): 'In a recent monthly report of the Connecticut State Board of Health, mention is made of a family in Thompsonville where there were eight cases of diphtheria with two deaths. This family lived in a house with a small back yard containing the well and privy as usual, but in addition a deposit of filth a foot thick on a level, composed of putrefying vegetable waste and a mongrel mass of nastiness. The ground sloped to the well and the deposit of filth came close to it. The windows of the bed-rooms opened on this yard. The family that moved out had been afflicted with malignant scarlet fever with several deaths. In quite a number of (other) instances there were from four to six cases in one family, or oftener all the members, and in all that have been carefully studied some sufficient cause has been found.' This quotation contains an almost exact description of two establishments in the vicinity of this post. One is known as the Post Dairy and the other the Butcher Pen, although fortunately neither place is now used for the purpose indicated by its name. They are both about two miles away, and in each the well was sunk in the position most advantageous to receive the drainage of two large and very filthy corrals (cattle yards). The contamination of the water from these wells was so marked that it offended sight, smell, and taste, and yet, because it was cooler than the water from a creek, which flowed near, the well water was generally drunk by the people of both houses. At the dairy there lived a widow with four small children, and two or three servants, one of whom, a young woman, had a child of four years. About six weeks ago, the oldest child of the proprietor was seized with diphtheria, which in succession attacked the entire family of children. Three died, and one (the first attacked) recovered. The child of the servant did not contract the disease, although it constantly played with the others and lived under the same conditions, except that its mother would never allow it to drink the well water, which the others drank freely. At the Butcher Pen, a man, his wife and two children, one eleven years and one eighteen months old lived. The father was generally away at work. The mother and older child had 'chills,' and four weeks ago the baby, which was still sucking, developed a case of diphtheria, which went on like the other cases, but on the fifth day began to improve, and gradually recovered. Although between two and three weeks have elapsed since the convalescence of the last case was established, no further cases have shown themselves. There was not, so far as I can learn, any exposure to diphtheria on the part of those who suffered from it. Indeed their isolated position rendered such a thing quite improbable. No child in the post has developed any diphtheritic symptoms. The 'police' (cleanliness) of this fort, however, is the special pride of its officers. As to the treatment, the two cases that recovered re-

ceived less treatment than those that died. Two of the cases were under my sole care. One, the only son of the widow, and her especial pride, received every care that could be bestowed upon him. I followed, as far as possible, the treatment which I understand Professor A. Jacobi adopts in diphtheria, including the lime-water spray, which certainly did this good, that there was no fetor about the case, which had been very marked in the preceding ones, where no spray was used. This case did not die from strangulation (because the child both spoke and swallowed just before death), but from heart failure, whereas both of the other children, if the mother's account can be relied upon, died entirely from 'want of breath.' In the boy's case stimulation and frequent feeding with beef-tea and milk were crowded from the first. The child at the Butcher Pen was ordered a piece of bacon about the throat, to be worn constantly. Throat to be swabbed every hour with a solution of iron and chlorate of potash, and three-fourths of a grain of quinine to be given in solution every two hours. On the fifth day an almost confluent pustular eruption (which resembled a confluent variola at end of first week) appeared all over the throat and parotid regions. The next day an abundant rash, like scarlatina, showed itself all over the body. The fauces and tonsils now began to look better. The ulcers on the latter were smaller and less sloughy, and the case went on to recovery. I should add that the treatment was inaugurated by a few small doses of gray powder and ipecac and one or two doses of castor oil. This, with the medication already mentioned, comprised the entire therapy in the case. I should have attached more importance to the rash spoken of, if it were not a usual thing on all children, sick and well, during our long and hot summers. It is gratifying to note that the well on the dairy premises has been filled up and the house torn down, and our post commander is endeavoring to have the same good work accomplished on the other premises, although unfortunately he has no direct control over them."

SOME "CURES" FOR HYSTERIA.—A writer in the feuilleton of *L'Union Médicale* discourses in an entertaining and instructive manner upon the course and cure of hysteria. "One is always instructed," says the writer, "in travelling. It is also a pleasure to observe for one's self the productions of the soil, the manners of the natives, the color of their umbrellas, and the price of their clothing. But how much more lively is the satisfaction when the chances of travel put us in possession of some precious novelty in the direct line of our researches and habitual occupations! This is what has happened to me. I have made a capital discovery in therapeutics, and I do not hesitate to announce it at once for the benefit of humanity, and without taking any of the preliminary risk of submitting it to the Academic committee on secret remedies. On a recent trip, I came across one of my old patients, whom, for convenience sake, I beg to introduce as Madame Lerond. We had not parted on very good terms, at which you will not be astonished when you learn that she is a respectable shopkeeper, of forty years, who suffered from hysteria of the vaporous form, with luxuriant manifestations as regards the head, stomach, intestines, limbs, and of all the organs and functions of the body generally. Not only had I failed to relieve Mme. Lerond from her various discomforts, but a cloud had marked the end of our mutual relations. *Voici comment*: One day she asked me seriously to tell her frankly, for the sake of her children, whether she was not threatened with insanity, and whether she would really ever be well. After explaining that her symptoms were only those of a nervous debility, etc., etc., I concluded: 'In fine, Madame, without ever being very sick, you will always be a little *patraque*.' I was much pleased with this expression, which seemed to hit her case very exactly. But my patient did not see the matter in the same light, and with a very cold air she told me that the word *patraque* seemed

to her very impolite, and she was not used to being treated in such a way. I tried in vain to explain that Littré defined the word *patraque* as signifying familiarly a person who was weak and invalidish, and that it was frequently used in the best society. These arguments failed to excuse my *soi-disant* enormity, my patient being equally unfamiliar with Littré and the best society. I departed, resolved thereafter not to essay expressions with my patients unless I was sure they would be comprehended.

Meeting Mme. Lerond on my travels, however, a year later, I ventured to approach and inquire after her health. She replied, in a very radiant and satisfied manner, that she was completely cured. 'I congratulate you,' said I; 'may I inquire how you secured this happy result?' 'It was a Russian physician who came to the store last winter, and desired, with much solicitude, to treat me. After having examined me very carefully, he assured me that he understood my case exactly, but he could not cure me at once, as he would have to send to Russia for the remedy. He had no confidence in French pharmacists, but by sending to Russia he would be absolutely sure of the purity of the medicine. The remedy having arrived, I took at first one pill. Next day the doctor came to inquire about its effects. It had not acted well. He then directed me to take two a day for four or five days. I felt myself instantly relieved, and since then have had neither headaches, nor insomnia, nor bad digestion, nor weakness.' The story was told with the greatest confidence and satisfaction. 'Do you know,' said I, 'Mme. Lerond, of what this famous remedy consists which has done you so much good?' 'I know very well, but I have forgotten. It was a yellow and bitter—it was—it was—rhubarb!' It was indeed rhubarb that had cured my old patient of all her ills; but the rhubarb came from Russia, and was given by a Russian physician. French rhubarb, given by a French physician, would never have done it."

The above account reminds the writer of some other "cures" for hysteria: "One of the best agents against the gastric and vaporous forms of hysteria is champagne, but only on the express condition that it be taken in a cup, not in a glass. I still see a former hysteric, who passed a dozen years of her life a victim of her nerves, eating each day but three pieces of barley-bread, and desolating her family with her *bizarrerries*. In her case it was not a Russian physician, but a *religieuse*, who brought about her cure, by simply announcing that she would die if she continued. She did not continue. Another case had been for four years the despair of all her acquaintance. She swung through the whole circle of physical perversions. The mode of her cure was neither rare nor curious, for it was simply through the care of a homœopathic doctor, of whom she still sings the praises, and who deserves credit for this trait of sagacity—that he specified, in commencing her treatment, that it would not last less than an entire year. This was, in fact, the most powerful and most suitable globule which the homœopath used in the whole course of the treatment. And so on *ad infinitum*. An excellent formula against hysteria would be, I think, the following:

R. Diplôme de Philadelphie,
Rhubarbe de Russie,
Fumisterie,
Homœopathie, āā q.s.
M.—Gild the pill."

A NEW JOURNAL.—The question whether Philadelphia or New York, Boston or Chicago, is the real medical centre, has been easily and simply decided in favor of the first-named city by the establishment therein of a new medical journal, *The Medical World*. We assert this, because the *World* is not an ordinary ephemeris, and its scheme of organization could not have been evolved from anything short of a real medical metropolis. The *World* has introduced the chrono-era into medical journalism, and offers four portraits of eminent medical men yearly to its subscribers. The first four eminent gentlemen are rumored to be already in Philadelphia sitting

for their pictures. The second four, it is expected, will soon be on their way, and we know not how soon it will be before Philadelphia is crowded with eminent gentlemen demanding lithographic recognition in the pages of our esteemed contemporary. That the appearance of the *World* is a subtle device on the part of Philadelphia to entice the leaders of our profession into its midst can hardly be doubted.

COLOTOMY IN FRANCE.—Colotomy, says the correspondent of the *Medical Press and Circular*, is an operation very rare in France, as the French surgeons have considered it a dangerous and useless operation. M. Pollaillon brought a case under the notice of the Academy. The subject was twenty-one years of age, who had a hernia on the left side since infancy. Two years ago the hernia became irreducible, and a neuralgia of the testicle of the same side, which was attributed to the weight of the tumor. No bandage could be borne under these circumstances. M. Pollaillon attempted the radical cure with an entire success. M. Guérin criticised the operation of M. Pollaillon, which, according to him, was not equal to his own, which he practised over forty years ago, and which consisted in practising a series of subcutaneous wounds; the exudation resulting formed a cicatricial tissue which completely obstructed the canal and thus effected the radical cure of hernia.

PREPARING FOR SCIENTIFIC WORK AT THE NEXT MEETING OF THE NEW YORK STATE MEDICAL SOCIETY.—We have received a circular letter, which we print below, from Dr. Hutchins, President of the State Medical Society. It contains an appeal to the members and delegates of the State Society to supply scientific material for the next meeting. We can heartily commend the President's effort in this direction. The circular reads as follows: "The By-Laws of the State Society provide that to the Business Committee are left all the arrangements for its scientific work. The Business Committee is not appointed till the opening of the session, so that all the control it has over this work is to receive any papers that may be offered, appoint the hour when they may be read, and apportion the time to be consumed in the reading. No authority, under the By-Laws, is given to the President, or to any Committee, to secure the presentation of any scientific matter. The By-Laws tacitly assume that such material will be offered. Whatever efforts the President may make, to assure an interesting and instructive session, are solely on his own motion, and the disposal of all papers thus secured is at the discretion of the Business Committee. The President strongly desires that the session of 1884 may be entertaining and profitable to the large number of medical men who will gather at the capital from all parts of the State in midwinter, and to this end this circular is addressed to all the delegates and members of the State Society, asking their personal interest in providing a suitable programme for the meeting. It adds materially to the general interest if all parts of the State are represented, as thereby are called out the most diversified experiences. The session of the Society is so short that the attractiveness of the programme is enhanced if the papers are short, or an abstract thereof prepared for reading. By this means a larger number of topics can be presented, and a fuller discussion permitted. It is hoped that this appeal may be seriously entertained by the delegates and members, and special preparation be made for the next meeting, worthy of so distinguished a body, representing such important interests. The President desires that titles of papers, with names and addresses of authors, may be forwarded to him at the earliest convenience. A list of these, in the order of their reception, will be prepared and laid before the Business Committee at the opening of the session. This will enable the Committee to consult the convenience of authors as to the time of reading, and contribute to the easy and full presentation of the Society's work."

CASES IN ABDOMINAL SURGERY,

WITH CONSIDERATIONS AS TO THE CAUSES OF DEATH.

By CHARLES K. BRIDDON, M.D.,

SURGEON TO THE PRESBYTERIAN HOSPITAL, NEW YORK.

THE following group of cases have come under my observation during the past few months, and I have thought them of sufficient interest to present to the readers of THE MEDICAL RECORD.

CASE I.—*Double ovariectomy, without adhesions; death in ninety-five and a half hours.*—Mrs. S. G.—, aged 45, married nineteen years, sterile; began to menstruate when twelve years old; has always been regular until the last year, during which the intermenstrual period has been sometimes three, on other occasions five and six weeks; the quantity has never been in excess. A year ago she began to be annoyed with a sensation of cold, covering an area of about two inches in diameter, situate about the middle of the front of the right thigh. In a few months this spot began to be surrounded by a halo of heat, and then began to be the seat of pain which radiated up and down the thigh; lately the same sensations have existed on the opposite limb. She began to grow stout after marriage, and two years ago was a woman of massive proportions, weighing about two hundred and fifteen pounds. Since then her abdomen increased considerably in size, but she was persuaded it was the accumulation of fat common to some women at the change of life. She never experienced anything unusual until December, 1882, when she had an attack of colicky pain in the right inguinal region that passed along in the direction of the colon; it only lasted a few hours, and when examined by her medical attendant he told her she had a tumor.

December 12th.—Patient is a stout, healthy looking woman, her face looks full and bright, and certainly does not indicate the existence of serious trouble. Her pulse, probably accelerated by my presence, is 92; respiration, 20; temperature, 99°. The abdomen is distended by a tumor that nearly fills the cavity; it is most prominent in front, is everywhere dull on percussion, save a space of about three inches between the superior limit of the tumor and the sternum, and laterally behind; the surface of the swelling is perfectly smooth, tense, and elastic, non-fluctuant, or I should rather say that the thick abdominal walls render the sense of fluctuation obscure and uncertain. The configuration is that of an ovarian or uterine tumor; it fills the abdominal cavity so completely that it does not rise and fall with the ascent and descent of the diaphragm; there is no crepitation. From sternum to umbilicus, 7 inches; from umbilicus to pubis, 10 inches; circumference at umbilicus, 48 inches; three inches below it measures the same. It is difficult to measure from the anterior superior spines, on account of the superimposed fat, but as well as I can ascertain, it is the same on both sides from those points to the umbilicus, namely, 10½ inches. It was with difficulty I could reach the os, which was thrown backward, and I could not map out the body, but made out that it was antevverted.

Examinations of the renal secretion gave the following results:

February 12th, night: specific gravity, 1.028; reaction acid; no albumen; amorphous urates; bladder epithelium; no casts. Morning: specific gravity, 1.020; reaction acid; no albumen.

February 13th, night: specific gravity, 1.028; reaction acid; no albumen; amorphous urates; bladder epithelium; no casts. Morning: specific gravity, 1.026; reaction acid; no albumen; amorphous urates; bladder epithelium; no casts.

February 14th, night: specific gravity, 1.032; reaction acid; no albumen; amorphous urates; bladder epithelium; no casts. Morning: specific gravity, 1.025; reaction acid; no albumen; amorphous urates; bladder epithelium; no casts.

February 14th, 8.30 P.M., to 15th, 8.30 P.M. (24 hours), passed a little less than a quart.

February 15th, 8.30 P.M., to 16th, 8.30 P.M. (24 hours), passed a pint and a half.

February 16th, 8.30 P.M., to 17th, 8.30 P.M. (24 hours), passed a little over pint and a half.

March 11th.—Patient complains of being distressed for breath. Circumference at umbilicus, 49 inches, three inches below it is 50 inches. It is impossible to find the xiphoid cartilage or the anterior superior spines, but the measurements are conjectured to be as before: there is at least two inches of abdominal fat that obscures the sense of fluctuation. It was only with difficulty I could draw the os forward, and I found it impossible to introduce the sound. I aspirated the tumor and withdrew about four ounces of fluid of the color and consistence of golden syrup; specific gravity, 1.014; alkaline; it coagulated on boiling, and the coagulation was dissolved by boiling with twice its volume of acetic acid (paralbumen). Under the microscope were found epithelial scales and plenty of large granular corpuscles. She was advised to keep her bowels regular with compound licorice powder, and take Buffalo lithia water.

March 28th.—Under the use of lithia the amount of urine has increased fifty per cent.

April 1st.—Has experienced some pain in the course of the left sciatic nerve, and a disagreeable sense of pressure in the rectum. Regarding the diminution in the renal secretion as due to pressure, and thinking that if permitted to continue it might compromise the results of an operation, early interference was advised, and it was contemplated to do it one week after the next menstrual period. Circumstances rendered it necessary to defer it a month longer; twenty-four hours before the day arranged for her to enter the hospital a case of erysipelas was found in one of the wards of the surgical pavilion, and it was determined not to admit her until all traces of this were got rid off.

Patient was admitted to the Presbyterian Hospital, May 5, 1883. A spacious room (4,500 cubic feet) in the administration building that had never been used, was prepared six weeks before her admission, by painting walls, ceiling, and floors; it was well lighted from the south and east, had apparatus for steam heating, and an open fireplace. A most thorough quarantine was established, bedsteads, bedding, etc., were new; nothing was permitted to come in contact with the patient that had been used in the Hospital Department. She was directed to have a warm bath every night, and to have her bowels regulated by compound licorice powder. Examination of urine for the three days after admission gave the following average: daily amount secreted 20

ounces; specific gravity, 1.025: reaction acid; no albumen or casts.

May 8th.—Had a light early breakfast, no lunch, an enema at 2 P.M. Preparations for operation as follows: No one was admitted to the room who had been engaged with any case of contagious or infectious disease; a reliable spray of pure phenol was used: all instruments: thoroughly cleansed and disinfected, were immersed in one to twenty solution: ligatures of silk had been boiled in one to twenty; fifteen large flat sponges had been thoroughly prepared by cleansing from sand and fat, and had been kept in one to twenty solutions for six weeks; temperature of room was between 75° and 80°.

Operation, 3 P.M.—Under the influence of ether it was possible to make a more satisfactory diagnosis. The tumor was found more movable, it could be lifted bodily upward, and the hands could be insinuated between its lower surface and the pubes. The uterus was found to the left and separate from the tumor; crepitus was also plainly elicited on moving the abdominal walls over the tumor; fluctuation was doubtful. An incision was made in the mesial line, commencing about two inches below the umbilicus and passing downward about six and a half inches. There was at least two inches and a half of fat in the superficial fascia; another layer of fat was found after division of the muscular aponeurosis—this of course was seated in the subserous connective tissue, and was very vascular. After the ligation of all bleeding points, the peritoneum was opened, exposing the cyst; this was found entirely free, there was not a single adhesion. Its walls were punctured with Spencer Wells' trocar, and after the evacuation of the largest cyst several smaller ones were treated in the same manner. The contents were so viscid as to occupy some time in removal, and when it was so reduced in size as to permit it, it was drawn through the opening in the abdominal walls, which were promptly closed, and maintained in coaptation by my friend, Dr. Watts, who assisted me. The pedicle was transfixed and tied on either side with a stout silk ligature, and supplemented by a second encircling the pedicle immediately below the first; the cyst was severed a quarter of an inch above the ligature. This large multilocular cyst was situate in the left ovary. The right was found to be undergoing the same process of degeneration; it was occupied by three cysts, united, about the size of a small orange: its pedicle was surrounded by a ligature and it also was removed. The two weighed with their contents sixteen and three-fourths pounds. The abdominal opening was then closed carefully with carbolized silk sutures, one-third of an inch apart, each suture taking up half an inch of peritoneum. The needles for introducing these sutures were made so that the punctures were no larger than necessary for the passage of the silk, and during their introduction the abdominal cavity was protected from the spray and blood from needle-punctures by a large flat sponge wrung out of warm carbolized solution. The toilet of the peritoneum was made as complete as possible, in fact it was left free of everything, and almost dry. The line of incision was covered with a strip of wet gauze protective, eight layers of freshly carbolized gauze and macintosh, the whole supplemented by a nicely fitting flannel bandage. The patient was placed in bed surrounded with hot bottles, and her head enveloped in a comforter. The House Surgeon, Dr. Freeman, was directed to let her sip hot water if she had any vomiting, and to give her occasional doses of tr. opii deodorata if she had any pain.

May 9th.—She vomited two or three times during the night; thinks the feeling of nausea was diminished by sipping hot water; had some pain, which required the administration of opium; it has now ceased; fifteen ounces of urine removed by catheter during the past twenty-four hours; temperature has reached 100°.

May 10th.—Was much disturbed during the night by a very heavy thunder-storm. Complaints of feeling faint, of

some abdominal pain and a constricted feeling, as of a band drawn tightly round the hips; her temperature went up one degree during the night, pulse 104. Noon today she began to vomit, and the matters ejected soon assumed the features characteristic of peritonitis. Metal refrigerating coil was applied to the head; tube was introduced into the rectum to facilitate the escape of flatus, and she was put upon aconite and opium. Toward evening hypodermic injections of bimeconate of morphia were substituted for the internal use of opium, and she was directed to be bed upon peptonized milk and Leube's solution of beef.

May 11th.—She slept greater part of the night. Vomiting ceased after the use of the bimeconate of morphia. Only twelve ounces of urine have been drawn during the past twenty-four hours, and it contained a trace of albumen. There is considerable meteorismus, everywhere resonant; no dulness, no fluctuation; pupils contracted, face flushed, pulse in the morning 100, went up toward evening as high as 120, respirations ranged between 13 and 18, temperature ran up to 102°. Toward night she began to perspire; the vomiting returned. Hypodermics of Magendie were ordered every four hours, and twenty grains of quinine per rectum. At midnight she was in a condition of stupor, respirations sighing and rapid.

May 12th, 3 A.M.—Pulse, 140; respirations, 24; temperature, 105°. Extremities becoming cold, hypodermics of brandy were given, but she gradually sank, regurgitating a thick, green, glairy fluid occasionally, and died at half-past three.

It is much to be regretted that an autopsy was not obtained in this case, as there are some conditions in the clinical history that could only have been cleared up by such an investigation.

I will now relate the history of a case of penetrating wound of the abdomen that was exposed to many of the influences that such pains were taken to exclude in the last case, and that did well in spite of them.

CASE II.—Report condensed from a history furnished me by Dr. H. B. McCarroll, House Surgeon. J. P——, native of Ireland, car-driver, twenty-seven years of age, single, was admitted to the Presbyterian Hospital, Sunday, May 27, 1883. Late the previous night, when engaged in a drunken brawl, he was stabbed in the belly. Excited by drink, he did not recognize the fact that he was wounded, and continued his debauch until midnight. On awaking in the morning he found something protruding from a wound in his belly, and his friends brought him to the hospital, twelve hours after the injury. His condition when seen by the attending surgeon (Dr. Briddon) was as follows: A large, strong, muscular man, he lay on his back with his legs drawn up; his face was ruddy, suffused from the effects of drink; his pulse full and strong, 72; respiration, 20; temperature, 100°. He makes no complaint of pain. On uncovering his abdomen a large mass of omentum was found protruding from a small punctured wound situate a little above and external to the centre of Poupart's ligament, its appearance somewhat changed by the length of time it had been prolapsed; its surface was sticky from effusion of lymph; it was ruddy red in color, and opalescent; it did not look as if it had suffered from strangulation, but only from exposure.

Treatment.—It was transfixed with a ligature of carbolized silk, which was tied on either side. It was then cut away, and after slightly enlarging the wound, the stump was returned into the abdominal cavity, which was closed with carbolized silk sutures. Small doses of deodorized tincture of opium were ordered to keep him quiet, and no other precautions were taken.

June 2d.—A case of erysipelas was found in a bed on the opposite side of the ward, which was at once removed from the building and placed in a hut used for the reception of such cases. The patient with abdominal wound was also removed into another ward.

June 4th.—A second case of erysipelas developed in

the ward into which the patient was moved, and at a distance of seventy-five feet from his bed. This case was also quarantined, and our patient was moved back into his old ward, which had been emptied and disinfected. On the third day his temperature reached 101° ; the following day it receded to 100° . His pulse never exceeded 92; in fact he did not have a single bad symptom, local or general.

The sutures were removed on the sixth day, and the patient was discharged cured on June 29th. He might safely have been sent out earlier, but it was feared he might strain the cicatrix if he was permitted to go out before it was quite firm.

Suppurating adherent cysts; double ovariectomy; septicæmia; chronic diffuse nephritis; death in ninety-six hours.—Reported by H. B. McCarroll, M.D. Mrs. L—, the patient, was admitted to the Presbyterian Hospital August 4, 1883. She is forty-four years of age, married, but has had no children. She enjoyed remarkably good health until thirty years of age, at which time she weighed one hundred and seventy pounds. Menstruation began at fifteen, and her periods were regular until fifteen years ago, at which time she was told she had anteversion of the uterus, which interfered with micturition and was accompanied by cessation of the menses and the occurrence of delirium and intense pelvic pain at the time when the menstrual periods ought to have appeared. Some months later the uterus was replaced, and all the symptoms abated and finally ceased. Patient was then quite well, with regular menstruation, until three years ago, when the periods became irregular, and one year ago finally ceased. Eight months ago she first noticed a tumor of considerable size in the right iliac fossa. It grew rapidly and attained its present size in a few months.

Examination.—Patient's general condition is poor. She complains of severe pain referred to the right lumbar region, at times extending across the back and down the left thigh. There is slight cedema of the left leg, frequent severe pains in the lower portion of the rectum, especially during defecation, and at times there is a discharge of blood from the bowels. Temperature, 99° ; pulse, 108. Urine: specific gravity, 1.020; acid; no albumen; quantity per diem, thirty ounces.

Physical examination revealed the presence of three abdominal tumors; the two larger were situated on either side of the median line, separated by a well-marked sulcus; they filled the iliac fossa, reaching about two inches above the umbilical line; the third was smaller, more tense and resisting, and was situated behind the larger one on the right side; it bulged the lumbar region. The tumors were distinctly fluctuant, but the larger ones were immovably fixed, the hands could not be insinuated beneath them, and they did not move during inspiration and expiration, crepitation could be made out laterally and above. Uterus anteverted and jammed down in the pelvis. The following measurements were taken: from ensiform cartilage to umbilicus, 7 inches; from ensiform cartilage to os pubis, 13 inches; right anterior superior spine of ilium to umbilicus, $6\frac{1}{4}$ inches; left anterior spine of ilium to umbilicus, $6\frac{1}{2}$ inches; circular measurement at umbilicus, 35 inches; circular measurement two inches below, $35\frac{1}{2}$ inches. A hypodermic needle was inserted in the tumors occupying the right and left lumbar regions and the fluid withdrawn from each contained a number of pus-cells, large and small. For three consecutive days preceding the operation an examination of the urine was made night and morning, with the following results:

First day, morning: specific gravity, 1.015; alkaline in reaction; no albumen; the microscope revealed squamous epithelium present. Evening: specific gravity, 1.018; alkaline; no albumen; contained triple phosphates, uric acid, and urates.

Second day, morning: specific gravity, 1.013; alka-

line; no albumen; contains some mucus. Evening: specific gravity, 1.016; alkaline; no albumen.

Third day, morning: specific gravity, 1.020; acid; a trace of albumen; pus-cells, uric acid, and squamous epithelium present. Evening: specific gravity, 1.020; acid; no albumen; contains few pus-cells and squamous epithelium.

Operation.—Performed by Dr. Charles K. Briddon, September 27, 1883, at 3 P.M. Patient under the influence of ether. An incision five inches in length was made in the median line and between the umbilicus and the pubis, when the subserous areolar tissue was exposed, all bleeding vessels were secured and the peritoneum was opened to the extent of the wound. It was then found that the omentum was drawn down in a fan-shaped process, adherent by its apex to the lower portion of the front of the cyst. Outside the lateral limits of the omentum, the cyst was adherent to the abdominal walls by bands that yielded readily to the pressure of the hand. The omentum was tied in two places and divided between. It was then found that more formidable adhesions existed below, and the worst of these existed in the true pelvis. The larger cyst was now pierced with a trocar, and when nearly empty of its viscid purulent contents and while it was being drawn through the opening in the abdominal walls, it was accidentally ruptured. In spite of the prompt application of large flat sponges, there is no doubt that some of the fluid entered the cavity of the peritoneum. The next step was to separate the adhesions situated in the cavity of the pelvis. These were most extensive in the very bottom of the cul-de-sac. They yielded without any great force, but the hemorrhage was very free and was arrested temporarily by sponges, and the pedicle of the larger cyst, which was found on the left side, was transixed with ivory needles charged with strong, closely twisted carbolized silk, and the mass was then removed. Attention was then directed to a second tumor, composed of several smaller cysts, involving the right ovary; the largest of these, about the size of a child's head, was reduced by tapping and the pedicle was secured as on the left side. The sponges were now removed from the cavity of the pelvis and there was found quite free hemorrhage from these points deep down in the very bottom of the cavity. It was very difficult to control this; the instant a sponge was removed a pool of blood obscured three points from which it issued, and when, after several unsuccessful efforts, the points were secured it was found equally difficult to pass and secure ligatures over the points of the forceps; in fact it was only done after turning the patient on her side opposite a window, which very much facilitated the manipulations. A thorough washing of the cavity was then made; it was several times filled with a hot solution of carbolic acid, and when completely cleansed, the abdominal wound was closed with carbolized silk sutures, a large glass drainage-tube being secured in the lower angle. The abdomen was covered with borated cotton secured in position by adhesive straps. Cyst and contents, independent of what was lost, weighed nine pounds.

September 28th.—Morning: Temperature, 101° ; pulse, 144; respiration, 22. Urine: specific gravity, 1.022; alkaline; no albumen. Patient rested comfortably during the night. The following method for washing out the cavity was devised: A long rubber drainage-tube was introduced through the glass tube, one end of which rested in the cavity while to the other end was attached a small funnel. The cavity was then thoroughly cleansed with a solution of boracic acid (gr. xvj. to $\frac{3}{4}$ j. of water) and the fluid was returned on the principle of the syphon. After cleansing the cavity thoroughly the drainage-tube was removed and in its place was substituted another, with a piece of lampwick running through its entire length. By this means thorough drainage could be obtained. Patient was ordered a diet of milk, mild stimulation, and opium in sufficient quantities to allay pain. Evening: Temperature, 103.5° ; pulse, 140; respiration, 32. Patient

somewhat restless, and complains of great thirst. No abdominal symptoms present. Urine: specific gravity, 1.022; acid: no albumen; amount passed, 28 ounces.

September 29th.—Morning: Temperature, 101°; pulse, 148; respiration, 28. Foul odor about the dressing; this was removed and the cavity thoroughly cleansed. Urine: specific gravity, 1.022; no albumen; acid in reaction: urates, triple phosphates, and squamous epithelium present. Evening: Temperature, 103.1°; pulse, 144; respiration, 28. Urine contains a trace of albumen; few pus-cells.

September 30th.—Morning: Temperature, 101.6°; pulse, 160; respiration, 28. Complains of a slight pain in right iliac fossa. Evening: Temperature, 105.6°; pulse, 160; respiration, 28.

October 1st.—This A.M., for the first time, casts were found in the urine; specific gravity, 1.020; acid; contains albumen, hyaline and granular casts. 2.15 P.M.: Passed into a comatose condition and died.

The following report of the pathological appearances has been furnished by the Pathologist of the Hospital, Dr. T. E. Satterthwaite: The tumors sent for examination, two in number, measured, the larger thirty centimetres in its greatest diameter, the smaller eleven centimetres in its greatest diameter. The larger contained 3,000 c.c. of a thick, tenacious, yellowish-brown fluid. The larger cyst had a thick fibrous wall, the interior of which was studded with papillary growths, the size varying from a robin's to a hen's egg. The smaller tumor appeared on examination, without opening, to be similar in character to the large one, and was multilocular. The fluid removed from these tumors prior to operation contained numerous pus-corpuscles, red blood-corpuscles, also the large granular corpuscles of "Glüge," and many cylindrical elements. The specific gravity of the fluid could not well be determined by the urinometer, on account of the density and tenacity. The fluids were tested for the various kinds of albumen, but owing to the great amount of pus no accurate conclusions could be reached. The fluid removed at the time of the operation presented the same microscopic appearances as the fluid removed before, except the cylindrical elements, which were absent. The fluid removed at the necropsy was less purulent than that examined before, but contained more blood.

Necropsy.—By William H. Reslin, M.D., Curator, twenty-nine hours after death. Body thin. Wound of operation in good condition. Thoracic cavity: Contents normal. Abdominal cavity: When the abdomen was opened no evidence of recent peritonitis was present. The wound of the operation had united, except at the lower extremity, where the drainage-tube was introduced. The peritoneum in the region of, and over the line of incision retained the glistening appearance of a normal serous membrane. The pelvic cavity contained about thirty cubic centimetres of bloody serum, but no evidence of recent peritonitis. There was, however, some thickening of the peritoneum, apparently chronic in character. The stumps from which the tumors had been removed were in good condition. Liver and spleen normal. The kidneys were slightly enlarged: weight, 155 grammes: capsules thickened and adherent, underlying renal surface granular; cut surface, pale; cortex slightly thickened. Microscopically the epithelia was found to be involved by granular and fatty degeneration; there was also a slight increase in the inter-tubular tissue. Chronic diffuse nephritis.

Remarks.—What circumstance or combination of circumstances might be regarded as responsible for the result in the first case of ovariectomy I have not been able satisfactorily to determine. Previous to the operation the patient might have been regarded as in the possession of perfect health, though it is true she was disabled by the bulk of the tumor and suffered much from its pressure effects. At the operation no adhesions were found. A minimum of injury was inflicted on the parts involved. A short incision might have sufficed but for the thickness

of the abdominal walls. There was not a single complication, unless the implication of both ovaries might be considered as one. Every recognized precaution against the known causes of death in such cases was strictly enforced to the minutest detail, and yet the patient died. Up to within the last few years it was considered prudent by many experienced operators to put off the operation until the suffrings of the patient demanded interference. Many reasons were assigned for such delay: it was considered that the emaciation consequent upon protracted disease was favorable to recovery; that the repeated attacks of peritonitis to which such patients are exposed destroyed the anatomical characters of the serous sac and its ability to resent traumatism by the usual process of inflammation. It is true that we do see many cases recover after very protracted and necessarily severe operations, the severance of almost universal adhesions, the use of almost numberless ligatures, the canter, rude handling, and long exposure of the sac. We see such cases progress favorably to convalescence with scarce a change in pulse or temperature, and when we see a case where the conditions all unite to warrant a favorable issue turn out badly, we naturally seek for the cause, and it will probably be by the careful analysis of individual cases that we shall eventually make out many of the causes of disaster. Delay is no longer considered as proper in cases of abdominal tumor. In addition to the suffering it entails, mental and physical, it exposes the patient to many of the accidents which belong to such cases, rupture of the sac, and the very various pathological changes, inflammation, suppuration, gangrene, and twisting of the pedicle, any of which conditions may render an operation imperative at a time or under circumstances that may jeopardize the result. The best authorities recommend an operation as soon as the condition calling for it is recognized.

Objection has been made to the performance of such operations in a general hospital. Such objections have been made by specialists, generally by gentlemen connected with institutions set apart for the treatment of diseases of women. I certainly would not sanction placing a woman who has been subjected to an abdominal section in a ward filled with cases of acute surgery; but if isolation is possible, and all modern precautions are taken, I can see no objection that would not equally apply to cases of strangulated hernia or penetrating wounds of the abdominal cavity, some of which, with protrusion of the viscera, resemble the conditions met with in the operation of ovariectomy, for instance, those in which masses of omentum have to be ligated and returned, and yet these cases do well. Are not the patients in special hospitals exposed to the same evils that exist in general hospitals? The wards in which patients have died of the common consequences of the operation, be those consequences simply inflammation or those more dreaded of infectious or contagious character, are again occupied by the same class of cases. Doubtless every precaution in the shape of disinfection is enforced, but this does not relieve them of the odium that attaches to the former. In my anxiety to avoid any preventable mischief in this case I put off the operation for a month on account of the presence of a case of erysipelas in an adjoining building; and yet, within a period of a few weeks, the second case related was admitted and exposed to the very influences I had so much dreaded in the first case. The man had been stabbed the night before his admission; his omentum had been protruded many hours; it was ligated and excised, and the stump was returned with no other precaution than the use of carbolized silk ligatures and sutures. A few days after a case of erysipelas was found within twelve feet of this patient; he was removed to another ward, where a second case of erysipelas was found. And yet, notwithstanding these exposures, he had an uninterrupted recovery; in fact, he had not a single untoward symptom.

It is the more to be regretted that we were not able to

obtain an autopsy in the fatal case, inasmuch as I have a lingering suspicion that the condition of the kidneys would have helped to explain the result. T. Spencer Wells, in the last edition of his work "On Ovarian and Uterine Tumors," refers to the influence exercised by functional disturbances of those organs on the results of the abdominal section. He expresses his opinion that in cases where the secretion is scanty the operation is apt to be followed by fatal suppression. In another place he says: "One condition which certainly requires correction before the operation is undertaken, is that common one where only a small quantity of highly concentrated urine depositing mixed urates in abundance is passed. If ovariectomy is performed on a patient in this condition, a serious amount of kidney congestion, with symptoms almost amounting to uræmic fever, is almost certain to follow the operation."

Lawson Tait, in his essay on "Diseases of the Ovaries," says: "Especial care must be taken to examine the condition of the urine, for the state both of kidneys and bladder is a most important factor in the success of the operation."

Vogel has calculated that a healthy adult ought to excrete per hour one cubic centimetre of urine for each kilogramme of weight of his body. The patient's weight, without the tumor, was about one hundred kilogrammes, and her average excretion ought to have been one hundred cubic centimetres per hour, and on referring to the history it will be found that it was very much below. The consequence of such a condition would be the accumulation of excrementitious material in the blood, and among the results of such contamination we find a tendency to inflammatory affections. Such were the opinions of Osborne and Traube, and their views have been corroborated by a host of other observers. Erysipelatous inflammations of the skin, purulent infiltrations in the pleural cavities, in the pericardium, less frequently in the peritoneum, and the localization of the inflammation may be determined by the condition of the part involved. In the case reported I was in doubt at first whether the symptoms on the third day were due to uræmia or peritonitis, but twenty-four hours' observation cleared up the doubt.

The condition of the kidneys, revealed in the autopsy of the last case, was sufficient to account for death. The scanty secretion of urine during the time she was under observation aroused suspicion, and repeated careful analyses were made, with negative results—facts unfortunately of too frequent occurrence.

RELIEF OF INTERNAL STRANGULATION BY ALTERNATE HOT AND COLD APPLICATIONS.—A man, forty-two years of age, who had some years previously suffered from a severe attack of peritonitis, was suddenly seized with violent colic. There was meteorism, the abdomen was generally tender on palpation, but more especially at a point a little to the right of the umbilicus. There was no passage either of fecal matter or of gas from the bowel, and purgatives, whether administered by the mouth or the rectum, brought no relief. The obstruction of the bowels continued several days, despite an active and varied treatment, stercoraceous vomiting set in and the patient was rapidly sinking. At this time, all other measures having been tried in vain, Dr. Roux (*Lyon Médical*, September 9, 1883) determined to try the effect of the alternate application of heat and cold to the abdomen. An ice-bladder was first applied and retained for an hour, then it was removed and compresses as hot as could be borne were placed over the abdomen. These applications were continued every hour through the day and night. In the evening some gas escaped from the bowel, and the following morning there was a slight stool. A mild purgative was now given and was soon followed by a copious evacuation, and the patient speedily recovered.

THE PLACE OF PANCREATIN IN THERAPEUTICS.

By J. S. HAWLEY, M.D.,

BROOKLYN, N. Y.

THE great importance attached to the nutrition of the sick, in modern medicine, has naturally and very reasonably led to the administration of digestive ferments to aid in the preliminary act of digestion, and also to the adoption of many devices for conforming alimentary substances to the impaired digestive functions, which attend all acute and most chronic diseases. This impulse has been so potent as to force the pendulum of medical opinion and practice far beyond the point of equilibrium, and which at the present time seems to oscillate between the extremes of scepticism on the one hand and an easy credulity on the other. The rôle which pancreatin is now playing in this important field of therapeutics, the wide range of its digestive activities, and the extraordinary attention which has been directed to its use by the late Lumleian lectures by Dr. Roberts, are sufficient reasons for inquiring into its proper use. It is by no means uncommon for men even of genius and learning, who have been fortunate or wise enough to make a step forward in the treatment of disease or the amelioration of human maladies, to be carried by their enthusiasm and the exaltation which attends success to attribute to their discoveries or improvements an extent of application which subsequent observation shows to be unwarranted.

This remark is well illustrated in the title given by Corvisart to the first pamphlet issued by him on the use of pepsine, "Dyspepsie et Consomption." The very great control over the processes of digestion and nutrition which his discovery of the use of pepsin afforded, impressed him with the belief that its influence would be sufficient to arrest the ravages of consumption.

The question to be discussed in this paper is not as to the relative value of different digestive ferments, but, admitting the value of all, to determine what is the rational and effective mode of using pancreatin. The proposition submitted, and an attempt to prove which will be made, is, that pancreatin cannot be effectively or usefully administered by the stomach, but can only be employed for modifying foods before they are taken. The argument will be presented in relation to the anatomical, physiological, and experimental aspects of the subject.

When we examine the anatomical arrangement of the alimentary canal, and the order in which the digestive ferments are delivered to and brought into contact with the ingested food, we are struck with this peculiarity, that they are generated and delivered at points remote from each other. Comparatively recent demonstrations have shown that the pancreatic fluid possesses three distinct ferments, viz., amylolytic, proteolytic, and emulsifying. Now it would seem to be a fair deduction and sound reasoning to conclude that if the pancreatic fluid could effectively perform these several offices upon crude food, then the salivary and gastric secretions were useless and in excess of any want of the system. But their presence is proof of their necessity, and the existence of ferments lower down in the elementary canal, supplementary to them, is proof that their action is preliminary, and the fact that their offices are performed where the next lower ferment cannot reach them is proof of their incompatibility. So much may be concluded by *a priori* reasoning from the anatomical arrangement. The physiological aspect of the case will be found in harmony with and confirmatory of the above. The gastric juice is not only known to be acid, but its ferment, pepsin, is inert in any other than an acid medium, while the pancreatic fluid is alkaline and is inactive in any other vehicle. This one physiological fact is sufficient to show that the two ferments cannot act together. One other physiological fact goes to establish the same conclusion, that is, the destruction of the pepsin in the duodenum by the action of the bile. Herman ("Elements of Human Physiology," p. 174),

speaking of intestinal digestion, says: "Solution of albuminous bodies is effected, most probably, by the pancreatic juices, as the activity of the gastric juice which reaches the intestine is destroyed by the bile." Dr. Lucien Corvisart, speaking of the pancreatic digestion (*Braithwaite*, No. xxxix.), says: "When the gastric and pancreatic juices are separated they act in succession, and thus the peptone may be doubled; but when mixed, the action of each is checked—they neutralize each other. Nature prevents this conflict, first, by separating the two juices by the pylorus; second, by the bile, which destroys the pepsin, as shown by Poppenheim." Certainly the demonstrated fact that the activity of the pepsin is arrested in the duodenum, not only by the alkalinity of its fluids, but by the direct agency of the bile, is fairly conclusive evidence of the incompatibility of the two agents which meet these. But the question still remains, Can pancreatin pass through the stomach, come out unimpaired, and in the duodenum take up its office and play the same rôle as freshly secreted pancreatic juice? In other words, can pancreatin be usefully employed by administration by the mouth?

The extensive use of remedies in which pepsin and pancreatin are combined, implies a belief on the part of many physicians that pancreatin *can survive* the action of the gastric juice and pass on unharmed into the duodenum, where it is free to perform its office. So far from this being the case, however, there are many reasons for believing that pancreatin is digested in the stomach like any other proteid. Lehman says, "the principal constituent of the pancreatic juice is a substance resembling albumen or casein." Herman ("Elements of Human Physiology," p. 142) says: "Its specific constituents are several albuminous bodies, which are scarcely distinguishable from albumen itself, and to which many observers ascribe the ferment action" (pancreatin). Now it is difficult to understand why a substance of the nature of albumen or casein should not be digested by pepsin, whose sole object and use is to digest albuminoids, and whose ability to digest that whole range of substances is well known. But the determination of this point does not rest upon inference. It has been shown by Kühne that "pepsin in acid solution actually destroys trypsin (one of the constituents of pancreatin); trypsin in alkaline solution does not possess the converse power of destroying pepsin, which, however, is altogether inactive in an alkaline fluid."

Mr. E. Scheffer, of Louisville, Ky., has demonstrated, by careful experiments, the fact that pancreatin digested with pepsin loses its activity in respect to all its properties. From a number of experiments, ingeniously contrived for the purpose of demonstrating this, want of space will permit quoting only two: First, "To a solution of one-half grain of pepsin, in two ounces of acidulated water, was added two ounces of pancreas liquid, obtained by rubbing down and beating three ounces of chopped pancreas with small quantities of water until after three strainings four ounces of liquid were obtained, which readily saccharified starch at the temperature of the air. The pepsin solution containing the pancreas liquid, after four hours' digestion, was filtered, neutralized, digested with starch-paste, and tested, but no sugar action was obtained." Second, "To two ounces of pancreas extraction was added a solution of one fourth grain of pepsin in two drachms of water, acidulated with five drops of hydrochloric acid, and the mixture treated as described before. Neither from the acid nor from the neutralized solution, after digestion with starch-paste, did I obtain any sign of sugar by Trommer's test; while the pancreas extraction, by itself, treated with starch, had given the most copious precipitate of oxidulized copper."

To the same effect are the following experiments, made by Dr. William Roberts, of Manchester, England,¹ for the

express purpose of determining the question under discussion:

"I prepared a solution of lactic acid corresponding in saturating power to the normal gastric acid (2 per 1,000 HCl). To fifty cubic centimetres of this dilute lactic acid I added five cubic centimetres of a solution of pepsin, and five cubic centimetres of an active extract of pancreas. I prepared a second similar, but substituted filtered saliva for the pancreatic extract. The mixtures were then placed in the warm chamber for one hour. At the end of this period the solutions were exactly neutralized and tested, they were both found to be absolutely inert, not a vestige of amylolytic nor proteolytic power had escaped destruction.

"I had an opportunity of testing the same question in a still more satisfactory way. While I was examining the throat of a patient suffering from an ailment which did not affect his general health, a portion of the contents of the stomach was ejected, and fortunately caught in a clean vessel. This was immediately filtered, and about ten cubic centimetres of clear acid solution was obtained. The period of digestion was three hours after breakfast. One-half of this was devoted to testing its saturating power. It was found to possess an acidity very nearly corresponding with that of normal chyme. To the remaining portion five drops of extract of pancreas and five drops of filtered saliva were added, and the mixture placed in the warm chamber for one hour, at the end of that time it was exactly neutralized and divided into equal portions. One portion was tested with a drop of starch mucilage and found to be absolutely devoid of amylolytic power. The other portion was added to an equal volume of milk rendered slightly alkaline with carbonate of soda, and was then placed in the warm chamber. Not the slightest digestive action was produced on the milk in twelve hours.

"With this evidence before me, I am unable to accept the conclusions of Defresne and others in Paris, who allege that saliva and pancreatic preparations can resist the normal acidity of the stomach in full digestion, and who recommend the administration by the mouth of pancreatic preparations during the period of chymification."

It appears then that the evidence afforded by the anatomical distribution of the digestive fluids, by the physiological constitution of these juices, as well as the conditions under which they perform their functions, and the results of experimental inquiry, all point to the conclusion that pancreatin not only cannot act in the presence of the gastric juice, but is deprived, by gastric digestion, of all power to perform its functions.

There remains one more aspect of the question to be considered, viz., Can pancreatic preparations by any device be protected from the action of the gastric juice in their passage through the stomach, in such manner as to preserve their digestive potency intact until they arrive in the duodenum, where the conditions are favorable for their action?

Dr. Fothergill proposes to accomplish this by administering ten or fifteen grains of bicarbonate of soda with a dose of liquor pancreaticus at "the tail of the digestive act." "This passes it securely through the stomach; just as a guard of soldiers sees a merchant convoyed over an unsettled frontier infested by robbers." Theoretically considered this expedient is open to several objections.

First, the alkali and the liquor pancreaticus are commingled, hence the pancreaticus is as much exposed to the attack as the alkali; as if the soldiers who were sent to guard a company of merchants should mix indiscriminately with their unarmed charge, an attack upon this promiscuous assembly would be as likely to prove damaging to the guarded as to the guards. If the alkali could be made in some way to surround the pancreatin, so that the acid gastric juice could be neutralized before the pancreatin became exposed, more certainty would attend the device.

¹ Lumleian Lectures, page 36.

Second, it must not be forgotten that ingesta of no kind pass directly through the stomach. It is the nature and office of the stomach to retain its contents, and to pour out gastric juice upon them. Under these circumstances how long would ten or fifteen grains of alkali resist the acid of the stomach? It is proposed to give the alkali and pancreatin an hour and a half or two hours after the ingestion of a meal, at "the tail of the digestive act." Does not the digestive act continue from four to six hours? Can "the tail of the digestive act" be determined? Does not every fresh ingestion provoke a fresh discharge of gastric juice? Certainly such a procedure, to say the least, must be subject to very great uncertainties. The stomach is well called an "acid gulf," "which we have to guard against, else our artificial pancreatic secretion is useless, of no earthly avail." It seems more probable that this "acid gulf" would swallow up any adventurous pancreatin which should attempt to cross it, than that the rash adventurer should cross it in safety. But, theory aside, it is claimed that clinical experience justifies the conclusion. It, however, should not be forgotten that clinical experience is invoked in defence of the use of pancreatin, not only unguarded by an alkali, but actually in combination with acidulated pepsin, which both Dr. Roberts and Dr. Fothergill assert to be fatal to pancreatin. The whole course of therapeutics is strewn with the wrecks of remedies which have been foisted upon the profession by the *supposed results* of clinical observation. Perhaps nothing is more delusive than a fragmentary and ill-digested collection of clinical facts. The sources of error are too numerous, and the conditions too complicated, to allow clinical observations to determine any important conclusion until many facts, well observed and carefully collated, have been brought to bear on the question. More especially must this be the case when the clinical observations contravene what are supposed to be well-demonstrated scientific facts, as in the case under consideration. Science will be of little avail in promoting the advancement of the medical art, if facts established by research and observation are to be lightly set aside by clinical observations short of absolute certainty. It seems far more reasonable to conclude that clinical experience will in the end conform to scientific demonstrations.

But whichever way the progress of observation and experience may determine this question, pancreatin has before it a wide therapeutic field. Second only in importance to the promotion of the digestive act within the organism is the adaptation of foods to the conditions of disease. The whole subject of the nutrition of the sick may be influenced by the use of this agent. The patent fact that the stomach, in common with all other organs of the body, is impaired by all acute and many chronic diseases, affords a wide scope for the use of artificially digested foods; but more especially is pancreatin likely to revolutionize the vexed question of infant feeding.

The principal obstacle to the successful administration of cow's milk is alleged to be the density of the coagulum formed by the action of the acids of the stomach upon the casein of the milk, thereby preventing its proper digestion. The devices for overcoming this difficulty have been numerous, but none of them entirely satisfactory. The use of pancreatin preparations appear to meet this difficulty fully. Dr. Roberts' ascertained by many experiments that pancreatin acts with great rapidity upon the casein of milk, and if not fully peptonizing it, certainly rendering it non-coagulable by heat or acids. This would seem to leave little to be desired in the matter of the adaptation of cow's milk to the purposes of infant-feeding. In the case of feeding infants upon farinaceous substances containing a large preponderance of starch, as they all do, the objection to their use is deemed to lie in the inability of very young infants

to saccharify starch, either by the action of the salivary or pancreatic secretions. This inability to digest starch has been attributed to non-development of the salivary and pancreatic functions, which, it is alleged, has been physiologically demonstrated. But over and above any demonstrations, such inability might well be inferred from the fact that infants are constituted to receive, and the Creator has provided for their use, a food which requires the action of neither salivary nor pancreatic digestion. The salivary secretion, being only diastasic, finds nothing in the milk to act upon. The gastric juice is amply sufficient to digest the casein, and as to the fat in the milk, it does not require the action of the pancreatic juice, for *all nascent milk* is in a *perfect state of emulsification*. So it appears that the infant is fully able to digest milk through the action of the stomach alone, and we may fairly infer that functions would not be provided for before there was need for their employment. This amylaceous aepsia of infants has been met by numberless devices, as is attested by the legion of infants' foods, which, by methods more or less effective, have been devised to overcome it. The most complete as well as the most scientific of these methods, is that known as Liebig's, which consists in saccharifying the starch by the action of the diastase in malt. This is an expensive and somewhat difficult process, so much so as to be unsuccessful in the hands of the average mother or nurse, and has consequently fallen into the control of manufacturers. But by the use of artificial pancreatic preparations this conversion of starch is accomplished with the minimum of trouble and skill. It consists simply in adding to the cooked food, at blood-heat, the pancreatic liquid, and allowing it to stand in a warm place one hour. A process so simple and so effective certainly seems likely to banish many of the infant foods which are now urged upon the attention of mothers and physicians.

The question, "What is the place of pancreatin in therapeutics?" may, in view of the facts set forth above, be confidently answered: Not as a remedy to be administered internally, but as an agent for adapting foods to the impaired digestive functions of the sick, and especially to the preparation of cow's milk and farinaceous foods for infant feeding.

THE LATE DR. GEORGE M. BEARD.¹

A SKETCH.

By A. D. ROCKWELL, M.D.,

NEW YORK.

MR. PRESIDENT AND GENTLEMEN—The date and place of a man's birth, some of the details of his earlier life, educational and otherwise, an enumeration of the amount, and an estimation of the character of his work—these in the main fulfil the necessities of the ordinary obituary record.

All these points have, however, been more or less fully dwelt upon in the various notices of Dr. Beard that have been written, and in complying with the altogether unexpected solicitation of the president that I prepare a brief sketch of my late associate to be read before this Academy, I shall confine myself rather to what he *was* than to what he did. What he did, in the way of professional literary work, must be known to all who keep abreast of the current of scientific research, although few have any conception of the vast amount of labor that was accomplished in the short space of his forty-three years. The simple enumeration of his various books, monographs, pamphlets, and magazine articles, would consume the time that can well be spared for this presentation, and I shall therefore, as an evidence of his wonderful industry, ask you to accept my statement that few of his age in this or any other country, equalled him in the amount or variety of his literary work.

¹ Lumléian Lectures.

¹ Read before the American Academy of Medicine, October 9, 1883.

Opinions will differ as to the value of some of it, but that most of it was original, stamped with his own individuality, and presented in such a clear and lively way as to compel attention, all must agree. The impulse in him to work was so strong, that in his waking moments I do not suppose he was ever absolutely idle; his mind was constantly busy, appropriating the facts and casual suggestion of every-day life, for a possible future use or reference. However great the pressure of professional or literary work, he was always ready to drop everything for the purpose of conversing. It made but little difference whether the one with whom he was in communication was intellectual or the reverse, he would listen as long as anything was to be said, and no utterance of value, or striking manifestation of character, escaped him.

I have often been amused and even amazed at the patience and gravity with which he would listen to the most trivial talk and the most absurd expressions of opinion, but I soon learned that these not infrequently constituted the basis of much that was strong and original in his writings. The power in him to formulate the crude ideas of others, seemed to be instinctive.

Much of the wide and deep meaning represented by common and constantly reiterated expressions, he in some way drew to a point, and gave to it a "local habitation and a name." As has been well said of him, "he worked because he loved to work; not as a slave, but as a child filled with and prompted by filial devotion, and in the very hour of his dissolution he expressed the hope that some one would take up his work at the point he left it and carry it forward, and he whispered the wish that he might be permitted, as a contribution to his work, to place upon record the thoughts of a dying man."

Among many illustrations of his devotion to work, I recall the fact that soon after the late war, and in the beginning of our professional relationship, I observed among his effects an immense pile of manuscript, which upon inquiry I found to be a work of fiction, written for want of something better to do, while serving as assistant surgeon in the "Gulf Squadron." Parts of it were intensely interesting, and contained many graphic descriptions of life and character as he saw it, and if published would undoubtedly have proven a valuable contribution. He however regarded it as of little account. Its purpose as a vehicle of expression when there was no special work at hand, had been served, and he allowed it to become scattered and finally destroyed. Such was the facility and accuracy with which his thoughts struggled to the birth in written language, that his pen was equally ready at his desk or in car or boat, and his manuscript seldom received a correction; but the publisher will not soon forget, nor will I, the sad havoc he played with the proof-sheets in his additions and emendations.

Perhaps the most striking trait of Dr. Beard's character was his humor. With an expression of preternatural gravity, he yet seemed as was said of Jean Paul Richter "to exist in humor; to live, move, and have his being in it." That shallow endowment termed irony or caricature, which often passes by the name of humor, but consists chiefly in a certain superficial distortion or reversal of objects, and ends at best in laughter, found little place in him. "True humor springs not more from the head than from the heart," and in Dr. Beard it found its best expression in his intercourse with those far below him in the intellectual and social scale, and so the relations formed with this class became immediately pleasant and helpful.

In him was illustrated Carlyle's remarkable statement that "Humor is a sort of inverse sublimity, exalting as it were unto our affections what is below us, while sublimity draws down into our affections what is above us. The former is scarcely less precious or heart-affecting than the latter; perhaps it is still rarer, and as a test of

genius, still more decisive. It is in fact the bloom and perfume, the effluence of a deep, fine, and loving nature, a nature in harmony with itself, reconciled to the world, and its stuntedness and contradiction, nay, finding in this very contradiction, new elements of beauty as well as goodness."

The reputation for a certain eccentricity which was so universally accorded to Dr. Beard, was in great measure due to this element of subtle humor, born with him, for between the intense solemnity of his countenance and the thought about to be uttered, there was such an utter incongruity, that it is not to be wondered at that the stranger or casual acquaintance should look upon him as something of an enigma. Therefore it was that few men in our profession have been so little understood, or as it might be put, more grossly misunderstood.

One of the most kindly and genial spirits that went in and out among us, he has been subjected to an amount of abuse, both public and by private communication, most unmerited. Amidst it all, he was to outward appearances as unconcerned as if every shaft was directed elsewhere than toward himself. Against those who struck the hardest and with the least provocation, the only revenge he ever sought or wanted was the exercise, at their expense, of a little of his inimitable and quaint humor; at times, not unmixed perhaps with a shade of contempt. On the contrary, a notable characteristic of Dr. Beard in his estimate of the life and work of others, was *tolerance*; and more than this, he practically held that no character was ever rightly understood until it has first been regarded *not only* with tolerance, but with *sympathy* as well. One other element of character which contributed not a little to this antagonistic feeling, was a positiveness of statement which, in the minds of many, could proceed only from intense and offensive egotism. That Dr. Beard was egotistic, in the sense of placing a high value on his own interpretation of certain phenomena in physics and psychology, as against the opinions of non-experts in these realms of science, cannot be denied. It was, however, that egotism that comes from the consciousness of a clearer and a keener insight, and no better evidence of its inoffensive character is wanted than the fact that those who knew him most intimately, found nothing disagreeable in the manner of these expressions of opinion.

As he said of himself, "he never argued, he simply asserted." This was the result partly, of a natural disinclination to polemics, and partly to a settled conviction, that the surest path to establish the truth as he understood it, was to boldly and persistently reiterate it.

Many instances could undoubtedly be given, where those who were in any way placed in opposition to him, would bear unreserved testimony to the height of his conceit; and from their standpoint, this judgment would be correct. On one occasion, he was in court giving testimony in favor of the plaintiff in a suit for damages. The defendant's counsel, an astute lawyer, after a severe cross-questioning, in which in every way, he attempted to belittle the attainments of the witness, suddenly asked him if he had not been in Germany lately. The answer was that he had. "For the purpose of learning, I suppose?" suggested the lawyer. "Not at all," was the answer, "I went over for the purpose of instructing them."

Not many years ago, in a somewhat celebrated trial, he had been on the witness stand several hours, and had sorely tried the patience of the cross-examiners by his cool assumption of superior knowledge, until in anger one of them finally said:

"Then it is to be presumed that all authorities who differ from you in this matter, are in error?"

"It is to be presumed that they are," was the reply.

Some have said that he sought notoriety, and worked selfishly for his own ends. In regard to this, I write in remembrance of the time, after our separation, when impelled solely by his ever restless instinct for research, he

neglected every expedient of private prudence, for the purpose of investigating along lines which could in no possible way bring in any return, and in this he persisted, until his practice, which was his only reliance, was so nearly ruined, that for the time being he abandoned it altogether for another field. He soon returned to it, however, and with what success is well known. After his death, there was found among his papers, a rather extensive pile of manuscript, which for a better name, might be termed a series of autobiographical sketches. I refer to them here because they illustrate many points of his character, and especially this tendency to humorous exaggeration of which I have spoken. Any one who knew Dr. Beard with any degree of intimacy, was aware that he seemed utterly destitute of any financial sense, so far as having any appreciation of the value of money, excepting as a present necessity. Accordingly, there were times in his earlier professional life, and occasionally up to within more recent periods, when he was closely beset by clamorous creditors, until to most people life would have been a burden. It was during one of these periods undoubtedly, that the portion of the autobiographical sketches was written, referring to the mutual relationships of debtor and creditor. A more unique and quaintly humorous exposition of this relationship I can well imagine was never before presented. From so much that is good it is difficult to select, but I will venture to give one short extract :

"I congratulate myself, that few persons at my time of life, have succeeded amid severe discouragements, in honestly acquiring so admirable a band of creditors ; in that select circle, are found names, of whom, if the world is worthy, certainly I am not. It is truly worth all the deprivations and obstacles, and misunderstandings I have encountered in my pathway through this vale of sorrows, to have been brought into such an intimate relation, for next to marriage, debt is the closest of all connections, and tends to make the parties concerned, thoroughly acquainted.

"It has been said by those who regard themselves as wise, that you must winter and summer with one, before you can know him, but I will recommend a shorter and surer road to acquaintanceship—the getting in debt to a man or allow him to get in debt to you. Such delicate relationships, bring out as I have noticed, the finer and subtler and least suspected qualities of human nature, that would never reveal themselves to any other test whatever ; indeed, no man can be said to know himself, until he has been either a debtor or creditor.

"Not the least of the charms of the relationship of debtor and creditor, if one may judge from his own experience, is its permanency ; in this feature it is certainly superior to wedlock, or to any other earthly relation. Marriages are followed too often by separations, divorces, or at least by infidelities ; but my creditors, or their representatives, are never long away, they never sue for a divorce, and are faithful unto death."

Let it not be understood from this that the subject of this sketch was indifferent to the claims of others. His readiness further on when the ability came, to meet these obligations, is sufficient evidence to the contrary, and I have alluded to this somewhat delicate matter, that the testimony of one who knew him better than most others, might be borne to the essential integrity of his character in this respect ; and while with the rest of mankind his imperfections are sufficiently manifest, it is an education, in this age of greed and gain, and backbiting, to have held communion with a man, who, so far as all outward evidences are concerned, seemed altogether free from envy, hatred, and malice.

Judged by many an accepted standard, he would be readily enough disposed of, and consigned by self-satisfied plodders to the oblivion appointed for all strange and misunderstood things, but tried by the great law of culture, which leads every man to become what from the beginning he was created capable of being, "resisting

all impediments, casting off all foreign adhesions, and show himself at length in his own shape and stature, be these what they may ;" judged, I say, by this standard, he represents to his contemporaries, an interesting, unique and lovable personality.

A CASE OF TARTAR EMETIC POISONING.

RECOVERY AFTER TAKING ONE HUNDRED AND SEVENTY GRAINS.

By JAMES STRATTON CARPENTER, M.D.,

RESIDENT PHYSICIAN EPISCOPAL HOSPITAL, PHILADELPHIA, PA.

THOMAS C—, aged twenty-one, employed in the dispensary department of the Episcopal Hospital, was admitted to the medical ward on the afternoon of June 30th, with all the symptoms of acute antimony poisoning. It was learned on inquiry, that, mistaking a bottle of tartar emetic for one containing cream of tartar (the latter having on several previous occasions satisfactorily relieved the constipation to which he was subject), he had poured out several teaspoonfuls of the drug into a tumbler of water, and then drank the solution.

No unpleasant symptoms occurred for a quarter of an hour afterward, when he was taken violently ill, and vomited, as he expressed it, "a wash-basin half full." This was followed by several more attacks of vomiting, accompanied by a burning sensation, which later increased to violent pain along the œsophagus and in the epigastric region. When admitted to the ward, half an hour after taking the poison, he was in a condition of extreme prostration, amounting almost to collapse, with coldness of the extremities, a weak, thready pulse, and the accompanying symptoms of a gastro-enteritis that were distressing to witness. The contents of the stomach having been thrown off, the continued emetic action of the drug but served to add to its depressing effect on the system, and after the most violent and oft-repeated efforts at vomiting, which were followed by the ejection of a few drachms of bilious fluid, or of mucus mixed with blood, the patient would sink back thoroughly exhausted.

The full emetic effect of the drug having been obtained, the indications to be met were : First, the administration of the recognized antidote, tannic acid ; and second, the proper remedies for a gastro-enteritis, accompanied by a most alarming depression of vital energies. Copious draughts of the tannic acid solution were accordingly given, and these followed by albuminous drinks, the deodorized tincture of opium being given for the burning pain complained of in the abdomen. The thermometer at this time indicated a body temperature of but 95° Fahr., and the radial pulse, which was scarcely perceptible, was slow and intermittent in character, and it seemed as though the hope were not to be realized, that in the violent vomiting which had first occurred enough of the poison had been gotten rid of to prevent a fatal termination.

In addition to internal stimulation with small and frequently repeated doses of spts. frumenti and liq. calcis, external stimulation by means of hot-water cans and vigorous friction of the chest, legs, and arms with heated towels was kept up, and it was only after three hours' unremitting care that reaction was established. The temperature rose to 99.5°, and the pulse improved in rate and force. The patient had a typical "rice-water stool," streaked with blood and accompanied by rather severe cramps in his legs several hours after his admission, but this was the only evidence of the intestinal irritation that occurred of that character.

The abdominal pain was largely overcome by the deodorized tincture, of which gtt. cxx. were taken within two hours, in addition to a hypodermic of morphia. The distressing thirst was a difficult feature of the case to meet, but a most grateful drink was obtained by cooling

the egg and milk mixture with ice, of which he drank frequently in small amounts.

At first the urine was scanty and dark-colored, but contained neither blood nor albumen. The after-treatment was the continuation of the milk diet, with entire rest in bed for three or four days, when the patient was discharged cured, and up to the present time, over two months since the accident, has experienced no further trouble.

The amount taken was not less than one hundred and seventy grains—which I ascertained by afterward asking the patient to pour from a bottle of the tartrate of antimony and potass. the amount he thought he had taken, and then weighing it—a rather imperfect method of ascertaining the fact, but, when it is remembered the object the patient had in view in taking the supposed "dose of salts," the estimate will not appear at all too high.

In this case it may be interesting to note :

First.—The length of time that occurred between the ingestion of so large an amount of the poison and the production of its first symptoms, as being in accord with the accepted idea of the action of tartar emetic upon the centres, absorption being first necessary, rather than its having any direct local irritant action upon the membrane of the stomach, and so causing the violent emesis.

Second.—The urine, which, according to some authorities, in the beginning of mild, and even of fatal cases, is increased in quantity, was in the present case almost suppressed.

Third.—The respirations, which are said to become altered in rhythm by the action of the drug on the respiratory centres, were unaltered in character.

Fourth.—There were no disturbances of sensory function, the ability to appreciate thermic irritants being attested by the patient's ready recognition of the elevated temperature of the hot cans with which his bed was provided.

Reports of Hospitals.

HOSPITAL OF THE UNIVERSITY OF PENN. SYLVANIA.

CLINIC OF WILLIAM GOODELL, M.D.,

PROFESSOR OF GYNECOLOGY IN THE UNIVERSITY OF PENNSYLVANIA.

ABDOMINAL TUMOR IN A YOUNG GIRL—REMOVAL OF THE OVARIES IN THE TREATMENT OF CONFIRMED MASTURBATION AND OF OVARIAN INSANITY.

GENTLEMEN: The first patient that I show you is a young girl whom I have not yet examined. I shall elicit the history before you.

She is seventeen years of age and single. Puberty began at the age of sixteen and she has menstruated three times, the last time being in the latter part of last December. There have been intermittent abdominal pains and some nausea.

She has menstruated. This shows that there is no congenital atresia and that a passage exists. Before the first menstruation she had a "good deal of pain in the abdomen," but she did not suffer at the subsequent periods. I have asked her about the color of the discharge, but there appears to have been nothing abnormal about that. Were there retention of the menses the discharge would be exactly like tar. By retained menstruation we mean that the woman has menstruated, but that owing to some obstruction, either in the neck of the womb or in the vagina, the blood cannot escape. The fluid parts are absorbed and when it does come away, it is a thick, tarry fluid. There has been nothing of this kind in the present instance. To complicate matters, it appears that she has a tumor.

The first thing that you should think of in all cases of

suppression of the menses is pregnancy. It is astonishing how many blunders are made on that very point. Only a short time ago a lady was brought to me from a very distant city by a kinsman (who was a physician) to consult me in regard to a tumor, which turned out to be pregnancy. Had she not been a kinswoman the physician would probably have discovered the nature of the tumor. I have had many such cases. Pregnancy is the first thing that you should consider in all these cases, no matter how unexceptional may be the character of the girl, for all are liable to fall as did David, although he was "a man after God's own heart." This patient came here on account of the suppression, and knew nothing about the existence of a tumor.

Here you see the tumor for yourselves, and the question arises as to its nature. If this were pregnancy we should look for labor in the latter part of this month, the menses having stopped in December.

I now turn to the breasts. In pregnancy certain changes take place in the areolæ, with which you are all familiar. They are, however, not pathognomonic, and depend to a great extent upon the complexion of the skin. Remember, also, that the excitement of having the breasts examined will sometimes cause a condition of the skin resembling goose-flesh, and a supposed enlargement of the glands of Montgomery. In the present instance the breasts are not altered, and they do not contain milk. Her complexion is remarkably good, being, in fact, quite florid, but this may be due to excitement.

The tumor is on the right side, movable, somewhat irregular, and rather high up. I can place my hand below it.

I shall now examine *per vaginam*. In private practice my favorite method of examining is to bring the woman's nates over the edge of a hard mattress and place her feet on my knees. I find the cervix pushed away back and I also feel a second tumor, which appears to be a prolongation of the tumor above. To the touch this feels like a case of multiple fibroids, but such a condition in a white girl of this age would be very remarkable. It would not be so in a colored girl. I find a central hymen. Still there might be penetration without rupture of the hymen. There are then two tumors; one directly over the bladder, which is plainly too large to be the womb, and a second tumor above, united to the lower one. With the greatest care, I have introduced the sound. The womb is to the left, and appears to be wholly independent of the tumors. It measures three inches, but further information I cannot glean, because she is so restless and nervous that it is impossible to make a thorough examination. My diagnosis at the present time is that there is a solid tumor of the womb or of the ovary, and I think more probably of the latter, and I fear of a malignant nature. If this tumor were a foetus, it must be an extra-uterine pregnancy, but extra-uterine pregnancy should not stop the menses. The womb evidently has no connection with the tumor unless it be by a long pedicle. She will not submit to the administration of an anæsthetic to-day, but I shall try to persuade her to return next week and allow us to administer ether in order to make a thorough examination.

Removal of the ovaries in the treatment of confirmed masturbation and of ovarian insanity.—Our next patient has been a great sufferer. She has been bedridden since May, but for a long time before that was a great sufferer. She sleeps very little, has constant ovarian and vesical pain and great distress in the back and pelvis. The pain radiates from the ovary, down the inside of the thigh in the course of the genito-crural nerve. She finds it impossible to walk, and, although well nourished, is a confirmed invalid. In addition to these symptoms, she is unable to pass her water, and had to have it drawn by a physician, until she learned how to introduce the catheter herself. I grasp a fold of the abdominal wall and you see that there is at least an inch of fat, showing that

she is well nourished. The expression of the face is that of health. You may lay it down as a broad rule, that when there is severe pain in combination with a well-nourished condition of the body the pain is not due to organic or structural disease, but is the result of nerve trouble. There are, however, some exceptions to this rule.

Before sending the patient out, I wish to show you hypertrophied nymphæ and a condition of unnatural redness which exists about the vulva. These are the only symptoms that can be seen. (The patient was now removed.)

This is an interesting case. This girl spent over four years in as many institutions before I saw her, and yet she is no better. When I observed her bright expression of countenance, and her well-nourished condition, I at once concluded that she was suffering from some nerve trouble. On making a vaginal examination I found such marked symptoms that I turned to the physician with whom I saw the case and whispered to him, "This must be a case of masturbation brought on by mental trouble." He said that such was the case and that it had been found out in all the institutions in which she had been an inmate. There was excessive hyperæsthesia of the parts, but no uterine trouble proportionate to the severity of the symptoms. There was some congestion of the ovaries and of the womb. The ovaries were very tender and could be felt from below, a little enlarged. The nymphæ hung down like dewlaps, and this generally indicates masturbation by attrition.

The history is that she had an early disappointment in love. This produced the mental trouble which caused the excitement of these organs. We are all emotional creatures, and during the sexual life these organs exert a great influence over both men and women. Love is not an abstract idea, not sheer cerebration, but a complex emotion. It is an alloy made up partly of mind, partly of body. In this case the result of the disappointment was a shock and congestion to the whole nervous system, and a shock to those organs so exacting during woman's menstrual life—the ovaries. She got into the habit of masturbating and has practised it ever since.

This is a serious case, one of positive disease, and is not to be sneered at or put to one side with a shrug of the shoulder. This girl is a terror to her parents, who are glad to get her out of the house. They have had to employ nurses without number, and she has worn all of them out.

What is to be done? Such cases as this one open a new field for investigation. I purpose to remove the ovaries. Here is a woman lost to society and a burden to herself and friends. I do the operation experimentally. Strange as it may seem to you, the site of sexuality in woman, as well as in man, has not been positively determined. Even in the eunuchs, who had been so before the age of puberty, the sexual desires are not wholly obliterated. On this account the Turks (among whom I lived for many years) demand not only the removal of the testicles, but also the amputation of the penis flush with the pubes. In order not to wet his clothes, every eunuch has to carry with him a catheter through which to urinate. We see the same thing illustrated in our streets to an unpleasant degree by the cattle, for the steers or young oxen play the part of bulls. Women in whom the ovaries have never developed possess no sexual feeling; but when the ovaries are removed after puberty it is questionable whether the sexual feelings are at all influenced. I know of cases in which keen sexual desires were not in the slightest degree blunted by the operation. In explaining such cases, some say that all of the ovarian tissue has not been removed, or that there may be several supplementary ovaries. There is a certain degree of logic in this reasoning, for abnormal cases of this kind do occasionally occur, but it is not wholly sound.

Four years ago we had in this building an abominable case of masturbation, and in the most repulsive-looking girl I ever saw. She was a patient of one of my colleagues,

who in vain did all he could to quench her inordinate desires. A consultation was therefore held by several members of the staff as to the propriety of removing the ovaries. I objected to this operation in her case for the following reasons: In the first place, the girl was here without friends to advise her, and was innately bad; I thought also that in the future she might give me trouble by prosecuting me for having unsexed her, and such a tale would tell well on a sympathetic jury. In the second place, I was not sure that the operation would have the desired effect of making her a respectable member of society.

I was asked some time ago by the superintendent of an insane asylum to spay a half-idiotic girl. It was impossible to keep her under strict surveillance, and the sexual feelings were so urgent that she was at the beck of the first comer. She had already borne two illegitimate children. I told him that I should feel humiliated in removing the ovaries simply "to let copulation thrive," but I was willing to perform the operation in order to prevent an idiotic offspring, an end which seems to me legitimate. At the same time I told him that I must have a written authority from the managers of his institution that I had their consent. After an interesting discussion, the managers decided not to give the needful permission, and so the matter fell through.

Less than a week ago I was called to an insane hospital to see a case of erotic insanity exhibited by masturbation and foul language during menstruation. I was to decide whether or not it was best to remove the ovaries. After a careful investigation, I could not detect any local disease whatever. There was tenderness of the ovaries, but no enlargement could be discovered. The girl was perfectly sane outside of the menstrual period, and was anxious to have the operation performed. The father and mother have also signified their consent. I told the doctor that, while I did not feel sure that extirpation of the ovaries would remove the sexual desires, it was an operation well worth trying, for, if it did not cure her, it would prevent her from bringing into the world an insane offspring. Further, that the operation could do no harm, unless the patient died, and that death in such a case was so questionable a harm that it would not grieve me. I should feel that I had done my duty, and that she and society were better off. On the other hand, when I remove the ovaries for other causes and the patient dies it grieves me to the quick. I shall probably perform oöphorectomy in this case next month.

The first case of oöphorectomy mentioned in history was performed for the purpose of abolishing the sexual feelings. This case may be apocryphal, although it seems to be as well authenticated as many other accepted traditions of old-time heroes. It is said that a Hungarian sow-gelder became so infuriated at his daughter's lasciviousness that he forcibly extirpated her ovaries; but history, if my memory serves me no trick, does not tell us whether or not she was more chaste after the operation, and this is the point that I am after.

The father of the girl whom I brought before you came to me and told me that if his daughter would not consent to the operation, that he and his wife wished me to do it by force. This incident shows how wearied out they were with her pains, and aches, and screams, and fancies, and other hysterical manifestations, whose name is legion. I told the girl what her father had said to me, and added: "You are twenty-three years old and your own mistress, and I shall not touch you without your free consent." This she gave me in the presence of several witnesses. I once removed the ovaries by force, but I shall never do so again, for it is an act that a jury might take an ugly view of. The case is as follows:

Several years ago, when about to attend a meeting of the State Medical Society, a physician of the city in which the meeting was to be held, wrote to me that he had a case of ovarian insanity which he thought was a proper one for oöphorectomy and requested me to bring

my instruments along. He took me four or five miles into the country to a dilapidated hovel, where I saw a wretched girl just coming out of a violent insane attack. She was insane all the time, but had frightful exacerbations about the menstrual period, so that for three weeks in every month she would be beyond all control. I found on examination that both ovaries were low down, enlarged, and extremely tender. I considered it a proper case for operation. The parents, worn out with care and fatigue, were very anxious to have the operation performed, and at once gave the necessary consent. In the afternoon we returned, forcibly administered ether, and removed the ovaries. She has been much benefited by the operation. All the violent symptoms are gone, but her mind is weak. Had her parents put her in an insane asylum she would have got well.

I have wandered from my subject, but while speaking of ovarian insanity, let me mention some cases that I have cured. All of these were accompanied by erotic feelings.

One was a married lady who about a week before the menstrual period would begin to be insane and become uncontrollable. These attacks would last for three weeks. After the paroxysm was over she would be perfectly sane. She had been to two or three institutions. Although the physicians in charge of these institutions objected to the operation, I removed the ovaries. She was restored to perfect mental and physical health. One of the gentlemen who had opposed the operation was converted by this case, and a short time ago sent for me to come to his asylum to remove the ovaries in an analogous case. I could not go at the time, and shortly afterward the patient died from some acute disease.

The second case was one of those cases lying on the border-line between insanity and hysteria. She had become alienated from her family, and imagined that her friends were her worst enemies. She had excessive menorrhagia, and had been bedridden for years. I removed the ovaries, and she got mentally well, while her physical condition was very much improved.

A third case was that of a lady of most excellent family. From an accident she had received a severe mental and physical shock. This was the beginning of the disease. Her health began to fail, ovarian turgidity appeared, and finally ovarian insanity developed. About a week before the menstrual periods the most horrible hallucinations would take possession of her, and she had mental fights such as Christian had with Apollyon. Later in the period she had an irresistible desire to kill a friend to whom she was most tenderly attached. Then, to save herself from injuring him, she made attempts to take her own life. She also suffered from menorrhagia, and was reduced to a condition of the utmost weakness. I was asked to see the case, and concluded with her physician that the ovaries were the seat of the trouble. After a good deal of opposition on the part of the family, the operation was successfully performed. Before the operation she could not touch meat because there was blood on it. Blood was on her clothing, in the air, and on everything around her. Like Lady Macbeth she saw blood everywhere. As she recovered from the effects of the operation it was interesting to watch these hallucinations gradually leaving her. Soon she was able to eat meat, and took large quantities of it. Now she is no longer insane; she is doing well, and is a wonder to all her friends.

I had another successful case, but at this moment I cannot recall the particulars of it. Were Dr. Baer present he would probably remember it.

In view of the fact that the removal of the ovaries has cured these cases, I think that it may do good in this instance. While I am not positive that the sexual feelings will be eradicated, I feel justified in performing the experiment. As regards the operation, it is performed in the following manner: A short incision is made below the navel in the linea alba, sufficiently long to admit two

or three fingers. Each ovary, with its oviduct, is seized, the pedicle, consisting of broad ligament and blood-vessels, is transfixed, tied, and cut off. The wound is closed in the usual manner, but everything is done under strict antiseptic precautions. Although I do not believe with Tait that the oviducts preside over menstruation, I always remove them together with the ovaries, because by doing so I get a longer pedicle, and am less likely to leave ovarian tissue behind.¹

Progress of Medical Science.

SYPHILITIC FEVER.—Dr. Duflocq relates in *La France Médicale*, of August 30, 1883, the history of a young man, twenty-five years of age, who was admitted to hospital suffering from a fever. The attack had begun eight days previously with headache and vertigo followed by vomiting, after which fever and diarrhoea came on. There was also epistaxis a few days later. On admission the patient presented nearly all the symptoms of typhoid fever: the tongue was white; there was tenderness on pressure in the right iliac fossa, though the belly was not tympanitic; the spleen was slightly enlarged; heart and lungs were healthy. The temperature was 104.7°. The eruption of rose-colored lenticular spots was confluent over the abdomen, and very thick over the arms, legs, and thorax. They were large, slightly elevated, and disappeared momentarily on pressure. It was the great extent of this eruption that excited suspicion and led to further examination. A cicatrix resting upon an indurated base was found upon the glans penis, and there were enlarged glands in the groin. Mucous patches were discovered in the mouth and fauces. The patient was placed upon ordinary anti-syphilitic remedies, and the fever and eruption disappeared in about two weeks. Dr. Duflocq mentions as of diagnostic value in the differentiation of typhoid from syphilitic fever, the early appearance (third or fourth day), and the abundance of the eruption.

MANAGEMENT OF LABOR IN COPENHAGEN.—Prior to 1877 a purely expectant plan was pursued in the management of labor at the Maternity Hospital in Copenhagen. If delivery was not accomplished within three hours, then resort was had to extractive measures. Since September 1, 1877, the method of expression has been employed in every case. In comparing the results obtained in two periods of four years each, by the old and new methods (1,780 of the former, and 1,559 of the latter). Dr. Weiss states that: 1, the frequency of hemorrhage occurring during the period of delivery has been markedly reduced; 2, retained placenta has been met with much less frequently since the method of expression has come into use; 3, rupture of the membranes has occurred more often; 4, post-partum hemorrhage is now of very rare occurrence. In view of these facts, the author thinks that midwives should always be instructed to manage labor in this way.—*Le Courrier Médical*, August 25, 1883.

A CANDLESTICK IN THE UTERUS.—The following curious case is found related in *Le Courrier Médical* of August 25, 1883. A woman, aged forty-nine, subject since puberty to periodical attacks of mania, but with lucid intervals, was admitted to hospital on account of an abundant and fetid leucorrhœa. Examination of the uterus showed a cervix covered with granulations and irritated by a discharge coming from within the womb. A sound which was introduced struck against a metallic body. This was removed and found to be the brass socket of a candlestick, measuring three-fifths of an inch

¹ On September 15th the operation of oöphorectomy was performed on the subject of this lecture, in a private room of the University Hospital. The ovaries and tubes had taken on cystic degeneration. The girl recovered promptly, but too short a time has elapsed to determine the issue of the operation.

in length, and four-fifths of an inch in diameter with a rim one and one-half inch in diameter. This socket was evidently detached from a candlestick introduced at some time into the vagina. The last pregnancy dated back twelve years, so the foreign body could hardly have been introduced at that time before the involution of the uterus. And yet it is difficult to conceive of a contracted uterus, in a woman past the menopause, seizing and drawing up into its cavity so large a body as that described.

THE TUNING-FORK IN THE TREATMENT OF NEURALGIA.—Dr. Rasori uses the tuning-fork in the treatment of neuralgic pains, applying it while vibrating over the course of the painful nerve. The sitting lasts about half an hour, when the patient is usually relieved without further treatment. He relates the case of a woman who had suffered from vomiting during the neuralgic attacks, but after the relief obtained by the application of the tuning-fork she was troubled no more in this way (*Cincinnati Lancet and Clinic*). The principle of this treatment is the same as that employed by Dr. Mortimer Granville. He uses an instrument, recently described in these columns, called the percuteur, by means of which he is able to make a number of taps in regular and rapid succession, and of varying intensity to any part of the surface of the body.

CURE OF OBSTINATE SCROTAL ECZEMA BY HOANG-NAN.—Hoang-nan is a vegetable substance of repute in Tonquin as a remedy against rabies, the bite of venomous serpents, leprosy, and several other grave affections. It contains nearly three per cent. of brucine and a small quantity of strychnine. Dr. Barthélemy relates in the *Bulletin Général de Thérapeutique* of August 30, 1883, a case of chronic eczema of the scrotum in which this substance was employed with most happy effect. The patient, a gentleman about fifty years of age, had suffered for ten years from eczema of the scrotum, perineum, and upper and inner parts of the thighs. He had consulted numerous physicians, and had tried every conceivable remedy without experiencing any relief. Dr. Geneuil, the last physician to whom he applied, having read of the efficacy of hoang-nan in leprosy, determined to try it in this case. The patient commenced with seven grains per diem, gradually increasing to forty-five grains a day, in divided doses. While taking these large doses he felt the physiological effects of the drug (muscular tremors, trismus, and vertigo), but persevered with the remedy, and was rewarded at the end of ten days by a perfect cure of his affection. The amounts taken were larger than had been advised by Dr. Geneuil. In all five drachms were taken. The patient was seen eighteen months later, and had then had no return of the eczema.

RECOVERY FROM LOCOMOTOR ATAXIA.—Dr. Louis Henry reported the following case to the Victorian branch of the British Medical Association (*Australasian Medical Gazette*, July, 1883): A man, twenty-nine years of age, of temperate habits, and free from any suspicion of syphilis, had been suffering for some months from symptoms of progressive locomotor ataxia. The distinctive signs of the disease were well marked and steadily increasing in severity. He was first put upon large doses of iodide of mercury, but as neither the fulgurating pains nor any other symptoms were improved after a two weeks' trial, nitrate of silver, in divided doses of one grain per diem, was substituted. The patient was anesthetized and the whole length of the spinal region was cauterized with the button of the thermo-cautery. The ulcers were kept open by a covering of a strip of linen smeared with resin ointment. The patient was further ordered the use of foot-baths of hot water and common salt three times a day; and during his stay in bed was to wear stockings containing powdered mustard. After about three weeks of this treatment, the nitrate of silver being gradually

forced to one grain three times a day, the resin ointment was removed, and the back allowed to heal. The legs were now massaged twice daily, and a solution of iodide of potassium, eight grains, and liquid extract of ergot, one-half drachm, ordered to be taken at 8 P.M. and 3 A.M., with the view of allaying the slight pains in the legs and controlling the emissions, which rarely, but occasionally still made their appearance. A very marked improvement now began to show itself. The pains in the lower limbs completely disappeared, the abdominal constriction vanished, the emissions ceased, the walk and gait became more sure and natural, and the patient regained sensation in his feet, so that, with his boots on, he could, when the report was made, feel the divisions in the wooden floor. For the past two weeks he had been taking eight-minim doses of the liquor strychniæ, and faradization was applied to the spine and lower extremities by means of a wire brush. The improvement, which was very evident, would, the author hoped, be permanent.

ABSENCE OF THE UTERUS.—Dr. Tschernoguboff relates the case of a woman, twenty-four years of age, well nourished and of good physique. The labia were of normal appearance, but the clitoris was very small. The urethra was so dilated as to allow the finger to pass readily into the bladder. The vagina was very short and ended in a cul-de-sac. Combined vesical and rectal examination could detect no trace of a uterus. The woman had never menstruated nor had she ever had any vicarious hemorrhages. She had been married six years, but every attempt at coitus was accompanied with severe pain.—*St. Petersburg Med. Wochenschrift*, August 25, 1883.

A similar case was related by Dr. Stanley O. Warren at the recent annual meeting of the Maine Medical Association (*New England Medical Monthly*, September, 1883). The woman was twenty-five years old, of English descent. She had had an irregular flow of blood, slight in amount, from the rectum since her eighteenth year, and thought at times that it had come from the vagina. She had been married once and was making preparations for a second marriage. Intercourse was always painful, though sexual desire was present. The external genitals were normal, but the vagina was but an inch in depth and ended in a blind extremity. The ovaries could be detected by rectal examination; they were connected by a band of firm tissue which might have been a Fallopian tube or a rudimentary uterus.

THE LIABILITY OF ERROR IN EXAMINING FOR SUGAR IN THE URINE.—The following illustrates with what care and precaution every urinary examination in regard to the presence or absence of sugar ought to be made. Professor v. Heusinger in a late session of the Aerztl. Verein, in Marburg, declared that a certain individual desired to be examined in view of having his life insured. At the close of the physical examination he was requested to urinate. As he had micturated before entering the doctor's office he now could pass but a slight amount. The chemical examination gave a yellow-green precipitate (saccharine). At the examiner's request the man returned the next morning, and the urinary test presented a negative result. It turned out after a close questioning that the individual had suffered for months with gonorrhœa, and had used injections of sulphate of zinc. He had passed water and used this injection just previous to presenting himself for the first examination. Dr. Fettiën, who was then consulted, found that if a solution of sulphate of copper is added to one of sulphate of zinc and tartaric acid and caustic soda in excess, a blue fluid is formed which contains, besides the constituents of Fehling's solution, sulphate of zinc. Added to boiling urine, the zinc is precipitated as a hydrate with a grayish-green color and the solution turns from blue to yellow. If albumen is added the same phenomena are observed, only the fluid above the precipitated zinc is reddish.—*Berl. Klin. Wochenschrift*.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, October 13, 1883.

THE MEETING OF THE NEW YORK ACADEMY OF MEDICINE, AND THE PROPOSED AMENDMENTS TO THE CONSTITUTION AND BY-LAWS OF THAT BODY.

WE think this institution, so important in every respect for the profession of this city, and we may well say for the country, is to be congratulated on its favorable progress toward a settlement of those difficulties which have for a time stopped its scientific work, and even dangerously imperilled its very existence.

Our readers are aware of the fact that at the meeting, April 19th, certain resolutions were passed, the main object of which was to instruct the Committee on Admission to report no physician for election as resident fellow who is known by the Committee to be in opposition to the Code of Ethics of the American Medical Association. A full report of the proceedings was given in our issue of April 28th.

The effect of this was to make a new test for election, not based on character, acquirements, or professional standing, but on belief. The resolutions were adopted by a large majority, at a meeting packed for the purpose, by inducing every one to be present who could be persuaded to vote for it, when no suspicion was entertained by those who could not conscientiously vote for such a radical change, that such a movement was to be attempted.

Two weeks before the present meeting the President sent a letter to every resident fellow, which will be found on another page, and certain proposed amendments to the Constitution and By-Laws which he deemed necessary to put the Academy in a good working condition, and to restore harmony and prevent all future trouble in the Academy. Very soon after, a circular card was sent to the fellows, which is also reprinted on another page. We especially call attention to this card, for we think all will agree that this is the most astonishing document that ever appeared signed by such distinguished names, as regards its audacity of statement and its English—particularly that of the last sentence. We are not surprised to learn that many supporters of the old code at once avowed their intention to vote for the proposed amendments.

At eight o'clock Thursday evening, October 4th, the President, Dr. Fordyce Barker, promptly took the chair. The hall was packed, filling the main room, the room be-

hind and the galleries, and very many were obliged to stand and quietly kept their places the whole evening.

After the routine business was finished, Dr. Austin Flint, Sr., rose to a question of privilege and asked leave to make a personal explanation: He stated that he had been frequently charged with inconsistency, in private and in public, in newspapers and in medical journals, and in other ways, in his action and conduct at two former meetings of the Academy. When the delegates to the Medical Society of the State of New York made their report in 1882, he then, at the request of the chief executive officer, whom at that time it would have been painful for him to deny any request he might make, moved, with entire heartiness, as it was in consonance with his own feelings, that the report of the delegates be accepted, and that further discussion of the topics and objects to which it referred be indefinitely postponed. He made the motion in good faith, because he believed that the discussion of ethics had no place in the deliberations of the Academy, but properly belonged to another society. At the last meeting of the Academy, he had voted for the resolutions of Dr. Austin Flint, Jr., and he had done so for the very reason that he believed their passage would have the same effect. He maintained that his conduct on both occasions was consistent and in harmony, and he hoped there would never again be a discussion of ethics in the Academy, either to-night or at any future time.

Dr. Flint was listened to with the closest attention and was applauded when he closed.

The President said he, and doubtless the Academy, had listened with great pleasure to the remarks of the gentleman whose name was held in the highest esteem by the profession, not only of this city, State, and country, but also abroad wherever there is a medical literature. He fully and cordially coincided with the sentiments expressed at the close of his remarks, and he hoped that the action of the Academy at this and the next meeting would effectively secure the result which both desired.

It was a favorable augury to see two men of the standing of the Ex-President and President again apparently working together for the same end.

A communication from the Council was then read, disapproving the proposed amendments and recommending their withdrawal. We have been informed that, including the President, there were present thirteen. That six advocated the foregoing communication and voted for it. The other six, thinking it of no consequence, as the Council had no authority in the matter, refrained from voting.

This statement was ready to be made, and the casting vote of the President on a tie would have been against the motion. But at this meeting it was found that the statement was not necessary.

Dr. Edward L. Keyes then moved the adoption of the proposed amendments of the Constitution and By-Laws.

In presenting these proposed amendments, Dr. Keyes remarked that he had been asked to do so by the President, and that he did so willingly, not only as a recognition of the great services the President had rendered the Academy, but also because he saw in their adoption an easy solution of the difficulties with which the Academy

was now surrounded, which difficulties would otherwise inevitably continue. He had always striven to live up to the old code, he was not a new code man, he had positively declined to join either party to the controversy now going on. It was therefore not in the interest of any faction, but wholly for the sake of peace, that he now offered the proposed amendments and moved their adoption as a whole.

Dr. Austin Flint, Jr., moved that the amendments take the usual course, and expressed the opinion that discussion on them at the present time was uncalled for.

Dr. Alfred L. Loomis seconded the amendments introduced by Dr. Keyes, and said that he did so gladly, for he was fully convinced that by their adoption the greatest danger that had ever threatened the Academy would be averted, and we should ever after be freed from such occurrences as had taken place at the last meeting. For the Academy to maintain its prosperity and its prestige, all matters of ethics and medical politics must be removed from it.

The President, interrupting: Every fellow has the power of expressing his approval or disapproval of any sentiments uttered by his voice if he can get the floor, or his vote, and I venture to suggest that it will better comport with the dignity of the Academy if all other modes of expressing either feeling be avoided.

Dr. Loomis, resuming: There were societies before which such matters properly came, but this was not one of them. The Academy was for scientific work and good fellowship, without fear of sharp tactics or bitter words. If the proposed amendments were carried, it would be impossible for any further disturbance of harmony to take place.

Our limits prevent us from giving more than a very brief abstract of the wise, temperate, and excellent remarks of both of these gentlemen, who spoke to the point, neither of them making any reference to codes.

Dr. Flint, Jr., disclaimed any desire to delay or obstruct the business of the meeting, but again urged that the amendments could not be acted upon to-night and ought not to be discussed. He renewed his motion, and it was now seconded.

Dr. C. C. Lee moved, as an amendment to Dr. Flint, Jr.'s, motion, that the Academy resolve itself into a committee of the whole, for the purpose of discussing the amendments. Seconded.

Dr. Flint, Jr., protested that his motion could not be amended.

The President decided that Dr. Lee's amendment was in order. It was put, and declared carried. A division having been called for, the amendment was found to have been carried by a vote of 135 to 15.

The President then said he considered fairness and courtesy required him to appoint as chairman one who stood on the record as having voted with the majority at the last meeting of the Academy. He should nominate one known to all as familiar with parliamentary usages, Dr. Ellsworth Eliot.

The Chairman named Dr. W. M. Carpenter Secretary of the Committee of the Whole.

By request the proposed amendments of the Constitution and By-laws were then read by the Secretary.

Dr. Louis Elsberg moved that when the committee

rise it report to the Academy in favor of the proposed amendments as a whole. Seconded by Dr. C. F. Taylor.

Dr. D. B. St. John Roosa thought fairness required that the President should have a chance to be heard as to his reasons for proposing the amendment.

Dr. Barker rose and spoke for about a half hour, commanding the closest attention and a peculiar stillness for such a large meeting, except when interrupted by applause. We regret that we can give but a brief abstract of his remarks.

He said he had not intended to take part in the discussion on the amendments, but was anxious to hear any objections to them that might be raised in a full and fair discussion. Since the request had been made, however, he could not hesitate. He repeated his gratification at Dr. Flint, Sr.'s, remarks. When, after the recent action of the State Society, it was feared that its action on the ethical question would be brought into the Academy, Dr. Flint, this renowned man whom he could not think of except reverently—had introduced a resolution to postpone the matter indefinitely. The resolution was carried unanimously, and had worked most successfully, until the action taken last spring, which had entirely changed the aspect of matters, and was, he thought, most injurious, imperilling the prosperity and usefulness of the Academy, inasmuch as it made two parties, the contention of which would keep out new members. He had, therefore, set about devising measures to undo the injury thus inflicted, and to guard against the possibility of further mischief of the sort. Without consulting anybody, but as the result of a careful study of the constitution and by-laws of similar scientific medical societies in Europe, such as the Royal College of Physicians, the Royal College of Surgeons, the Royal Medico-Chirurgical Society of London, the British Medical Association, the Academy of Medicine of Paris, and others, he had prepared the amendments of the Constitution and By-laws now before us. The ethics of these amendments were in every respect as high as those of any of the societies that he had mentioned. He had hoped that for the sake of the Academy he would have the support of those who had raised a perpetual monument to their memories by their liberal gifts in building this beautiful hall, in filling the shelves above us, and by their long untiring work for the Academy. He felt that they never would be willing to see their labors come to nought, and this property of the Academy, which, the Chairman of our Board of Trustees said the other evening, amounted to one hundred thousand dollars, practically ruined. All know that property devoted to a special purpose most rapidly depreciates when it fails of its object. He had been greatly pained when he found that his judgment was wrong, as he was sorry to say it often was, and that some of the best of these men were opposed to these amendments, which he believed so necessary for the future of the Academy.

This course reminded him of the farmer who saw a hawk on the ridge-pole of his barn, which he thought had stolen his chickens, and ran into his house, seized his gun, and fired at him. The wadding from his gun set fire to his barn, which was burned with all its contents. But the story is not ended, and there is another moral.

A bystander, who had listened to the story with gaping mouth and breathless suspense in all its details as to the size of the barn, how much it had cost, how many tons of hay, bushels of wheat, rye, and corn had been burned, exclaimed at the end, "Did he kill the hawk?"

Dr. Barker then explained his amendments, and answered some objections which had been urged. The Committee on Education was omitted, simply because it had no practical duty or utility; the Committee on Ethics, because its functions were relegated to the Council, and because it abolished an inquisitorial committee which was always liable to do as much harm as good. Unfortunately, there has grown up, from the unhappy controversy now going on, a kind of distinction between ethics in its highest and best sense and what is technically called the "code." He would advocate for the Academy the highest ethics, both in theory and practice, and if any of its fellows were found wanting in this particular, he would adopt a slang phrase of the day and say, "turn the rascals out." The resolutions passed at our last meeting made it absolutely imperative, in the interest of the Academy, that in the amendments all allusion to the code should be left out. If this was a misfortune, the responsibility will rest with those who introduced the resolutions.

Dr. Barker then alluded to some other objections, which had been urged.

Dr. Flint, Jr., thought that every one present knew, before the President's explanation, precisely what the amendments implied—they struck out the Code of Ethics, and the other amendments had had to be made to correspond. The report of this Committee of the Whole would amount to nothing. It was simply impossible for the amendments to obtain a three-fourths vote at the next meeting. Therefore, their introduction could only act as a firebrand. Discussion was wholly unnecessary, and he, and those who thought with him, would not take part in it.

The President moved to amend Dr. Elsberg's motion as follows: *Resolved*, That in the opinion of the Committee of the Whole it is advisable that the amendments to the Constitution and By-laws proposed this evening be adopted as a whole, and that the Chairman be so instructed to report. He also gave notice that he would subsequently move that, when the Committee rose, it should report progress, and ask leave to sit again on October 18th.

[A motion to rise having been made and seconded, it was put and declared lost.]

The President again brought up his motion instructing the Committee, and it was now seconded and declared carried. A division having been called for, the motion was found to have been carried by a vote of 103 to 34.

On motion the Committee rose, reported progress, and asked leave to sit again October 18th.

On motion of Dr. H. G. Piffard, the Committee's request was granted.

The President then took the chair.

Dr. Flint, Jr., moved that the amendments lie over until the next meeting, under the rules. Carried.

The meeting then adjourned.

As the matter stands, the amendments are now in the hands of the Committee of the Whole, and no motion in

regard to them, or action on them, can be taken by the Academy until the final report of this Committee.

It now seems nearly certain that so large a number of supporters of the old code feel it necessary to save the Academy, that the amendments will secure the requisite three-fourths vote.

We should think it not at all improbable that all opposition to the amendments may be abandoned in order to prevent the new code party from claiming a victory by the action of the Academy of Medicine. Weak, timid generals are very fearful of changing front during the time of battle. But Dr. Flint, Jr., does not belong to this class. Like Bismarck, he would not hesitate for a moment to give up a fight where he has nothing to gain and much to lose by victory.

The real battle on the "code" is to be fought at the County Medical Society, October 22d, where Dr. Flint, Jr., has frankly and squarely made the issue, and put at the head of his ticket the strongest man possible who would be sure of nearly an unanimous election, were it not that the election does not rest alone on the interests of the society and personal merits.

THE CLINICS OF NEW YORK CITY.

We present in another column a schedule of the clinics to be held in this city during the coming season. The total number per week is over one hundred and sixty, giving an average of about twenty-eight clinics each week-day.

The clinics in general medicine and surgery naturally take the lead in number, there being between twenty-five and thirty of each of these weekly. Eye and ear diseases, children's diseases, gynecology, neurology, come next in popularity.

Over two-thirds of the clinics have been established within the past year by the schools for post-graduate instruction.

New York has about forty public and private hospitals, with a capacity of over seven thousand beds. There are twenty-five dispensaries, treating a quarter of a million of people annually. There is, therefore, abundant material even for the numerous clinics.

ARTIFICIAL IMPREGNATION IN ITS MEDICO-LEGAL ASPECTS.

A CASE of much interest to the medical profession has recently been brought before the civil tribunal at Bordeaux. It appears that a certain physician in Bordeaux advertised widely that he was able to cure sterility in either sex, and no matter how obstinate. Attracted by these pretensions, M. and Mme. A., a childless couple, went to the quack and secured his services. The operation known as artificial impregnation was performed, but, as the evidence shows, in a bungling and incomplete manner. Conception did not take place, but on the contrary, some local injury was done. Despite the failure the quack claimed his fee, which was the moderate sum of fifteen hundred francs, and accused the woman of having attempted abortion. The case was brought before the court, which not only refused to award the fee but condemned the operator and the operation.

The decision does not affect the legality of the opera-

tion itself, but the judge condemned it as being a procedure which was unnatural, and which might, if abused, be a source of danger to society.

Artificial impregnation is an operation which in certain cases may be justifiable, but which is generally resorted to with extreme caution by gynecologists. The practicability of artificial impregnation was first shown upon the lower animals by Spallanzani in 1782. Dehant and Sims, about twenty years ago began to attempt it upon human subjects. In fifty-five separate experiments upon six patients, Sims only succeeded once, and he has now abandoned the operation. Some French gynecologists still endorse it.

LATHYRISM.

TOWARD the end of the last century, Duverney called attention to the danger of eating wild vetches, and described a paralysis of the lower extremities caused thereby. Since that time several observers have described lathyrism, and in 1880 a paper was presented to the International Medical Congress by Dr. Brunelli, giving the histories of several cases of this affection. At the meeting of the Paris Academy of Medicine of July 7, 1883, Dr. Proust detailed a series of observations made by him in an epidemic of the disease occurring recently in Algeria. The first symptoms appeared suddenly after a cold and wet night, and resembled those of a transverse myelitis, viz., high fever, lumbar pains, formation and trembling, motor and sensory paralysis of the lower extremities and paralysis of the bladder. In time, these symptoms were succeeded by those of degeneration of the lateral columns. The patients presented a very characteristic appearance. Locomotion was difficult and only possible with the aid of a cane. There was rigidity of the lower extremities. The feet were in extension and adduction, it was impossible to bring the heel to the ground and walking was accomplished on tip-toe. The patellar tendon reflex was greatly exaggerated and the ankle clonus was also marked. The eyes were unaffected and there were no lightning pains nor any other signs of ataxia.

No autopsies were made, but from the symptoms observed it is probable that the lesion consisted in a transverse myelitis or a hemorrhage of the cord, succeeded by degeneration of the lateral columns. The disease was apparently caused by a species of wild vetch (*lathyrus cicera*), called by the Arabs djilbes, which enters largely into the diet of the natives. All who were attacked had eaten of this vegetable, while among the tribes who did not use it there was not a single case.

The immediate exciting cause seemed to be exposure to cold, and moisture. M. Proust suggested that the injurious effects of the vetch might be due to a mildew. The disease would then be analogous to pellagra, the supposed cause of which is the *sporisorium maidis*, a parasite of Indian corn. Repeated examination, however, failed to show any diseased condition of the djilbes, while experiments upon animals would seem to demonstrate that the poison exists in the healthy plant. A resinous substance contained in the grain of the lathyrus caused death with paralytic phenomena when given to rabbits. The same paralytic phenomena were observed by Bourlier in animals poisoned by the ethereal or alco-

holic extract of lathyrus. The prognosis was generally favorable. In some cases a spontaneous cure was observed, while in others it was obtained as a result of treatment. This consisted in the administration of iodide of potassium internally and counter-irritation with croton oil or tincture of iodine applied along the spine. This report suggests the advisability of a careful study of the physiological action and properties of lathyrus. We may then possibly find that a potent drug can be added to the neurologist's armamentarium.

News of the Week.

A SUCCESSFUL RESECTION OF THE PYLORUS for cancer was recently made by Professor Heinecke, of Erlangen.

THE NEW MEDICAL COLLEGE AT QUINCY.—A correspondent of the *Peoria Medical Monthly*, announcing the organization of a new medical college at Quincy, Ill., states that the Decatur physicians are not going to be behind-hand, and will presently organize a rival institution. The writer says that the following will go into the prospectus: "For some time we have been convinced that the obstacles thrown around the pathway to the medical profession by designing men are altogether too numerous, and it shall be our endeavor to do what we can to fill the decimated ranks of the profession, and in this way help to hold up the hands, enlarge the sphere of usefulness, etc., of those who have already chosen this noble profession. We believe it cannot be successfully controverted that where members of our profession are most numerous, there the health of the community is in the best state of preservation. This being an undisputed fact, we shall labor for the good of mankind by so decreasing mortality, in filling the ranks of our profession, until we may see in every city and hamlet throughout this glorious republic of ours, one physician to every one hundred inhabitants."

A NEW MEDICAL COLLEGE IN CINCINNATI has been organized under the title of The Medical University of Ohio.

CONCERNING REPORTED LEPROSY IN WISCONSIN.—We have received a communication from Dr. J. T. Reeve, Secretary of the Wisconsin State Board of Health, regarding a remark made in a recent editorial that leprosy was "said to prevail to a considerable extent in some of the Scandinavian colonies in Wisconsin." "This report," Dr. Reeve states, is unfounded. He thinks it doubtful if there is at present a single case of the disease in the State. A few cases of leprosy have been brought into Wisconsin by immigrants from Norway, but not one case, as far as can be ascertained by the most careful inquiry, has ever originated there, and the disease can never be said to have "prevailed to any considerable extent."

THE EPIDEMIC AT THE NEW YORK INFANT ASYLUM, MOUNT VERNON, N. Y., AND THE CAUSE OF THE EXCESSIVE DEATH-RATE.—Dr. B. J. Burnett, Health Officer of East Chester, N. Y., submits the following facts in reference to the rate of mortality at the Mount Vernon branch of the New York Infant Asylum: "An epidemic unquestionably has invaded the above institution, the nature of which is more a matter of conjecture than ac-

tual knowledge, I opine, on the part of those who *ought* to possess definite and accurate opinions, in control of this institution. On the first day of August last there were contained in the above asylum 236 *children*. During August there were 23 *deaths*, and during September 33 died, a very heavy percentage you perceive. From the death certificates in my possession it would be a difficult matter to ascribe this excessive rate of mortality to any particular disease, as each of the certificates referred to specify from *two* to *five* causes of death under head of chief or determining, and from *one* to *three* of consecutive or contributing causes." This is a serious charge from a responsible source, which, we hope, can be satisfactorily explained by the asylum authorities.

YELLOW FEVER AT HAVANA AND VERA CRUZ.—During the week ending September 28th there were nine deaths from yellow fever at Havana. There were eight deaths from yellow fever at Vera Cruz during the week ending September 20th.

THE FOOD VALUE OF AMERICAN FISH.—Spencer F. Baird, Commissioner of Fish and Fisheries of the United States, in noting the editorial in *THE MEDICAL RECORD* for September 29th, urging the taking of steps for investigating the food value of American fish says, that this subject has occupied the attention of the Fish Commission for several years; and that since 1878 Professor W. O. Atwater, of Middletown, Conn., has been carrying on, practically, at its expense, a series of researches far exceeding in magnitude, and scientific as well as economical value, any others on the same subject. Professor Atwater is now in Germany, engaged principally in this work, which is still very far from being completed. He has, however, made several partial reports, one of which was published in the "Proceedings of the American Fish Cultural Association for 1882." A more elaborate report, containing the fullest possible data in regard to about sixty-two species of American fishes, is now in type, and will appear in a forthcoming volume of United States Fish Commission reports.

DEATH OF A MEMBER OF THE FRENCH CHOLERA COMMISSION.—M. Thuillier, one of the scientists sent under the direction of Pasteur to study the cholera in Egypt, has himself fallen a victim to the disease. He was the youngest member of the party, being but twenty-six years of age. He contracted the disease in the cholera hospital of Ghedid, in Alexandria, where he was engaged in its study. His funeral was attended by all the Europeans resident in the city, the consuls, the medical corps, members of the other cholera missions, and the English army surgeons.

THE MEDICO-LEGAL SOCIETY held its stated meeting on October 3d. Prof. John J. Reese read a paper entitled "Report of a Toxicological Examination for Arsenic." Mr. Charles F. Wingate read a paper entitled "Sanitary Laws relating to Building in New York."

THE PHILADELPHIA MEDICAL TIMES.—The editorship of this journal has been changed, and Dr. Frank Woodbury has been promoted to the position. We congratulate the publishers on having secured the services of so accomplished and experienced a gentleman.

Obituary.

SURGEON GENERAL CHARLES H. CRANE, UNITED STATES ARMY.

BRIGADIER-GENERAL CHARLES H. CRANE, Surgeon-General, United States Army, after a brief service of one year and two months, died suddenly at 6 A.M., October 10th, at Washington, in his fifty-eighth year. His predecessor, Surgeon-General Barnes, was retired under the act of the Forty-seventh Congress in August, 1882, and lived but a short time after his retirement. Surgeon-General Crane was President Arthur's personal choice, and his death, so wholly unexpected, was a great shock to him. A few weeks ago he complained of a severe cold, which irritated his throat and made respiration irksome. He went about performing his official duties until two weeks since, when, under the advice of his physicians, he remained at home. Two days before his death the symptoms became alarming, though it was not supposed the patient was beyond the reach of medical skill. Several of the eminent surgeons of the army were in constant attendance, and though no attempt was made to conceal his condition from the family or the public, the fatal result of the throat hemorrhage was a shock to official circles in Washington. Both Surgeons-General Barnes and Crane were attendants at the bedside of President Lincoln, and in the pictures extant of his last moments it is Surgeon Barnes who is feeling the pulse of the dying President. He was born in Rhode Island, but was appointed to the army from Massachusetts on February 14, 1848. After several promotions he was, on March 13, 1865, made Brevet Brigadier-General for meritorious services during the war of the rebellion, and on July 28, 1866, was promoted to be Colonel and Assistant Surgeon-General, and afterward Brigadier-General and Surgeon-General, July 3, 1882.

His remains were interred at Shelter Island, N. Y., yesterday afternoon, the following distinguished gentlemen being pall-bearers: Secretary Lincoln, General Sherman, Admiral Rodgers, Robert C. Schenck, Generals McFeely, Rochester, Rucker, Drum, Beard, Benet, Hunter, Holabird, Wright, and Perry, Commodore Fillebrown, Dr. J. M. Brown, United States Navy; Mr. Ross Ray, and Mr. Charles Knapp.

Reports of Societies.

THE AMERICAN ACADEMY OF MEDICINE. *Eighth Annual Meeting, held in New York, October 9 and 10, 1883.*

H. O. MARCY, M.D., PRESIDENT, IN THE CHAIR.

(Special Report for *THE MEDICAL RECORD*.)

THE meeting was called to order by the President on Tuesday afternoon. A number of members from Philadelphia, Washington, Boston, and elsewhere were present, the whole number of registrations being forty-seven. The entire afternoon was devoted to reading papers, having as their general aim the encouragement of a higher and broader medical education. An exception was that of an interesting sketch of the late

DR. GEORGE M. BEARD,

by DR. A. D. ROCKWELL. The paper, which is published in full on page 399 of *THE RECORD*, described Dr. Beard's studious habits, his sense of humor, his vigorous self-assertion, his literary industry, and his tolerance of others, even the humblest and most illiterate.

DR. TRAILL GREEN, of Easton, Pennsylvania, read a paper on

THE IMPERFECTION OF TECHNICAL STUDIES AS A MEANS* OF MENTAL CULTURE.

His theory was that technical studies might give special skill, the skill of the craftsman, but that they did not and

never could really educate a man in the broad sense of the word. Technical studies, perhaps, fitted a man for money-winning in many directions, but did not equip the man best for the needs of a learned profession.

DR. CHARLES MCINTIRE, Jr., of Easton, Pa., read a paper entitled

IS IT FAIR? A STUDY OF THE COMPARATIVE POLITICAL POSITION OF THE MEDICAL PROFESSION IN THE UNITED STATES.

Dr. McIntire showed how full the profession was of ignorant and incompetent persons, also how politically powerless and apathetic its members were. He inveighed against the indifference which both the public and physicians showed in allowing the country to be so flooded with persons who were really dangerous to human life and morality.

DR. BENJAMIN LEE, of Philadelphia, read a paper entitled

THE VALUE OF AN ACQUAINTANCE WITH BOTANY AS A PRELIMINARY TO THE STUDY OF MEDICINE.

He deprecated the neglect into which the study of botany had fallen among physicians and medical students. The result had been caused by a narrow utilitarianism, which made exhibitors and prescribers of drugs rather than enlightened physicians. The paper gave a historical review of the progress of botanical study in this country during the closing years of the eighteenth century and down to the present day.

DR. A. L. GIBON, U.S.N., read a paper entitled

THE HIGHER PLANE IN MEDICINE.

A standard of preliminary education that will go far enough to embrace a knowledge of the natural sciences, and of the structure and use of language; a graded curriculum of four years; a rigorous examination for graduation by disinterested boards; a three-years baccalaureate probationary to the doctor's degree. All these are not enough, if preceptors, professors, and physicians in general fail to impress upon their pupils that medicine is something more than an *art*, merely seeking to relieve individual suffering at so much a head; that its wider aim is to banish disease from the earth, prolong life, develop and improve the race, and thus increase the total of human happiness; that there is no grander or sublimer employment of the intellect than this study of man and his surroundings, catenated as it is with every other branch of knowledge; that he who is really "learned in medicine" is learned in many things, and moves in that higher plane which should be the aspiration of every man who presumes to add M.D. to his name.

For those who are content to look no higher than the requirements of a daily routine, it were better to make no pretence of education, but to recognize a class of general practitioners who can pull a tooth, apply a poultice, or chance a dose of calomel or castor-oil. Consign them to the *limbus fatuorum*, but do not claim for them equality and fraternity with educated physicians. The line must be sharply drawn. There can be no border land. If the degree of M.D. is to be presumptive evidence of professional ability, see that it is the exponent of something definite. Repudiate sham colleges and sciolist teachers, and relieve the profession from the burthen of the gross ignorance, illiteracy, and incompetence which are now its opprobria.

EVENING SESSION.

The President, DR. H. O. MARCY, delivered his

ANNUAL ADDRESS.

The progress of modern thought was touched upon, and the query made whether medicine had progressed at an equal rate with other sciences.

The value of sanitation and the necessity of more earnestly studying and applying its laws was urged. The impurities of the air were enumerated, and the dangers

encountered in badly ventilated rooms described. The organic dust in the air was believed to be the cause of the mysterious "epidemic constitution," so-called, and to be connected with the spread of disease and of surgical complications.

The impurities of water were described, and the consideration of soil-pollution in water-supply dwelt upon.

Numerous diseases are caused and distributed by impure water. The soil air was also a source of danger little considered. The power of these soil and water impurities has been shown by the disastrous effects of typhoid fever in Massachusetts. From 1840 to 1880 there were 390,000 cases of typhoid fever, with 40,000 deaths. In the war there were 93,433 deaths from injuries, and 186,216 deaths from disease. Of these latter deaths, 108,666 were from zymotic diseases alone. Besides this there were 1,700,000 cases of diarrhoea and 1,100,000 cases of dysentery. The number of deaths in 1830 in the United States from diphtheria was 38,398; from typhoid fever, 22,905.

The speaker had made some special experiments with germicides, and had reached conclusions much like those of Koch and Sternberg. Corrosive sublimate in a strength of 1 to 2,000 was as powerful as carbolic acid in a 1 to 20 solution.

The discoveries of Koch regarding the tuberculous bacillus, and its specific relation to phthisis, were thought by the speaker to be established. Some conclusions regarding the bacillus were given.

The disposal of the dead was a problem that needed attention.

The prospective development of the medical profession and of medical science were eloquently dwelt upon.

At the close of the address numerous micro-photographs of the lower organisms were shown.

The Society then adjourned to a supper.

SECOND DAY—WEDNESDAY, OCTOBER 10TH.

A telegram was received announcing the fatal illness of Dr. F. D. Lente.

ELECTION OF OFFICERS.

The Council reported the following nominations for officers:

President—Dr. Benjamin Lee, of Philadelphia; *Vice-Presidents*—Dr. Nathan Allen, of Massachusetts; Dr. A. L. Gibon, U.S.N.; Dr. George F. Shrady, New York; Dr. Edward J. Birmingham, New York; *Secretary and Treasurer*—Dr. Richard J. Dunglison, of Philadelphia; *Assistant Secretary*—Dr. Charles McIntire, Jr., of Easton, Pa.

The report of the Committee was accepted and the officers elected.

Dr. J. Marion Sims was elected honorary member. Twenty-six new Fellows were elected.

DR. L. S. PILCHER, of Brooklyn, delivered an address on

THE RELATIONS OF MEDICAL JOURNALISM TO HIGHER MEDICAL EDUCATION IN AMERICA.

Dr. Pilcher began by deprecating the somewhat too radical conclusions announced in some of the papers on the day before, regarding the absolute necessity of an academic training in order to be a useful physician. It would not be to the advantage of the Academy to have such an opinion go out as representing its views. The speaker instanced Hunter, Cooper, Paré, and Velpeau, as persons who had brilliantly succeeded as physicians despite their having been without a classical training. The speaker also protested against the slurring manner in which the *art* of medicine had been spoken of in comparison with the *science*. Harvey had been instanced as an example of what education, learning, originality, and skill could accomplish. Harvey, however, was unskilful in the art of medicine, while his contemporary, Sydenham, not a scientific man, was a brilliant *physician*.

"There is now," the speaker continued, "a revolu-

tion going on in the methods of medical teaching. The use of technical appliances, laboratory teaching, quizzing, etc., are now a part of the teaching system, so that now the average medical graduate is crammed to an extent which was not the case twenty-five years ago. It is a question, however, whether he is any better physician than he was formerly. The function and object of medical education was to make real practical physicians, those who could relieve pain and cure disease. That system of education which makes the best physicians in this sense will be the one finally adopted. Other things being equal, the person who has first had a good general education will have the advantage over others in the end."

The speaker was inclined to think that the increase of medical colleges was not an unmixed evil, owing to the effect of competition. The licensing of students by these colleges was, however, a mistake.

The speaker then took up the subject of medical journalism. The rapid growth of medical journalism was a sign of the increased education and mental activity of the profession. The fact that the great publishing houses were willing to put their capital into the large weeklies was an evidence of appreciation of the intelligence and educational ambition of the profession.

In the discussion of the paper, DR. STEINER said that in organizing the Academy the chief object was distinctly formulated. It was to encourage young men to secure a preliminary collegiate education before studying medicine. He protested against an attempt to discuss the primary object of the Association as a waste of time.

DR. HUNT, of Boston, speaking for outsiders, asserted that academic training was inconsequential and useless. He thought the real reform needed by the profession was closer adaptation to the methods of science.

DR. A. L. GIBON, referring to Dr. Pilcher's remarks, said that Hunter, Velpeau, and Cooper were not graduated in two years, but really had a long and careful preliminary education.

DR. SIBBETT spoke briefly, defending the aims of the Academy. The conditions of life and opportunities for education are very different now from those of a hundred years ago. Of eighty medical men in his county only three had the degree of A.B. Not five had ever contributed to medical science or literature, because they were not sufficiently educated.

DR. J. CHESTON MORRIS, of Philadelphia, read a paper entitled

THE MILK SUPPLY IN LARGE CITIES.

The importance of milk as a food, the dangers to infant life of its impurities, and the methods of delivering and of adulteration were enumerated.

The use of sealed jars for the delivery of milk was recommended.

There was a great difference in the quality of the milk of different kinds of cows. Thus the common native cow gives 1 pound of butter to 17 pounds of milk; the Devon, 1 pound of butter to 14 pounds of milk; Jersey, 1 pound of butter to 12 pounds of milk; Durham and Ayrshire, 1 pound of butter to 17 pounds of milk. The Devon cow contains more sugar and caseine, and its milk is more nutritious. The composition of milk was given. The total amount of milk annually consumed in Philadelphia was estimated to be 55,548,417 quarts, or about two-fifths of a pint daily to each inhabitant. The cost averaged \$100,000 a day.

DR. A. D. ROCKWELL read a paper entitled

THE EXACT VALUE OF THE ELECTROLYTIC METHOD.

The writer said he had long ago given up the attempt to treat malignant tumors by electrolysis. In a case of epithelioma of the face, however, he had recently obtained an entire disappearance of the growth. In some cases of intramural fibroids he had had remarkably good success. An illustration case was cited. In erectile tumors he had had his best results. One operation is generally sufficient.

The best method of procedure was to connect the needles with the positive pole and place the negative pole outside. The resistance is greater, but this can be overcome by increasing the number of cells. Cystic tumors can be as successfully treated as the erectile, but practically the application is less often needed.

Dr. Rockwell's conclusions were:

First.—The success met with in the treatment of malignant tumors is generally but trivial. In epithelioma, however, when superficial and easily reached, success may be had.

Second.—The electrolysis of *intramural* fibroids often reduces the size somewhat and gives great relief.

Third.—For erectile and small cystic tumors electrolysis is a specific.

Fourth.—Goitres, if small and soft, may be reduced in size, even by external applications. Even when hard, electrolysis may be beneficial, but the results are variable.

Fifth.—Hairs can be permanently removed.

Sixth.—In many cases of stricture, relief or cure can be obtained by electrolysis, but experience is not sufficient to speak of its value positively.

THE REPORT OF THE COMMITTEE ON PROGRESS OF MEDICAL LEGISLATION

was read by DR. R. J. DUNGLISON. The report stated that the progress made in the past few years had been most satisfactory. The views of Dr. Miller, of Minnesota, were quoted, in which he stated that the laws of West Virginia, Illinois, Minnesota, and Missouri were the best. It was stated that considerable disappointment had been felt as to the success of the registration law in Pennsylvania and New York. The workings of the new law in Mississippi, modelled after the Illinois law, passed in 1882, had already been very successful. The attempts of the Illinois Health Board to promote higher medical education were detailed. A list of the States which possessed some medical laws was given as follows: Alabama, Arizona, Arkansas, California, Colorado, Connecticut, Delaware, District of Columbia, Florida, Georgia, Illinois, Kentucky, Louisiana, Maryland, Michigan, Minnesota, Mississippi, Missouri, Nebraska, Nevada, New Hampshire, New Jersey, New Mexico, New York, North Carolina, Ohio, Pennsylvania, South Carolina, Texas, Vermont, Virginia, and Wyoming Territory.

Since the last meeting of the Academy laws had been passed in Delaware, Michigan, Minnesota, and Missouri. The efficacy of the laws in the different States varied greatly. The following States have *good* laws, according to Dr. Rauch: North Carolina, Alabama, West Virginia, Illinois, Missouri, Minnesota, New Mexico, Wyoming Territory, Mississippi, and Louisiana; ten in all. Pennsylvania still lags behind, her law being little more than a registration regulation. New York's law has been much criticised. It was still thought a good law in the main by many, but needed a severe penalty for perjury. In Alabama the diploma confers no right to practise. In Arizona, Pennsylvania, and Washington Territory, the law is simply for registration. In Arkansas a bill for a medical law failed last year. In Texas and Nebraska the law is weak and ineffective. In Tennessee there is no law, and the practice of medicine is "free to all." In Utah there is no medical law except that provision of the penal code which punishes a physician who is drunk.

DR. R. S. SUTTON, of Pittsburgh, read a paper on the "Importance of Cleanliness in Surgical Operations."

[The paper will appear in full in a subsequent number of THE RECORD.]

DR. BUSH read a paper entitled "A Few Words Concerning Vaccination."

At the close of the reading of the papers, the new President, DR. BENJAMIN LEE, was introduced.

The Academy then adjourned to meet next year in Baltimore, Md.

NEW YORK PATHOLOGICAL SOCIETY.

*Stated Meeting, September 12, 1883.*GEORGE F. SHRADY, M.D., PRESIDENT, IN THE CHAIR.
THROMBOSIS WITHOUT EMBOLISM.

DR. VAN GIESON said that at the last meeting of the Society he presented a specimen of thrombosis occurring after parturition, and then expressed opinion that it was not due to embolism. [See MEDICAL RECORD, vol. xxiv., p. 246, September 1, 1883.] Since that time he had seen a case of very severe phlebitis, affecting both femorals, with apparent partial obstruction of the femoral arteries, at least the impulse of the arteries was very much diminished, occurring in a woman sixty-five years of age; at the present there is more or less coldness of the lower extremities without any distinct evidence of gangrene. Dr. Janeway had seen the patient, but his opinion concerning the case Dr. Van Gieson had not yet learned. He had, however, examined the heart very carefully, and, so far as physical signs go, found it entirely free from any evidence of valvular disease or hypertrophy. The occurrence of this case so soon after the one reported, and the absence of any evidence of cardiac lesions, still further inclined him to the belief already expressed, namely, that obstruction from thrombus is not necessarily due to embolism. In other words, there are cases of thrombus which occur independent of any mechanical obstruction by embolism; whether or not the change occurring in the intima of the affected vessel might be called inflammatory, he was unable to say.

DR. AMIDON asked if, in the last case, there was any evidence of the presence of the contracted kidney of Bright's disease?

DR. VAN GIESON replied that repeated examinations of the urine had failed to reveal any evidence of kidney disease.

DR. AMIDON said the reason he asked was because it is well known that, not only in syphilis, but in chronic interstitial nephritis, the condition of endarteritis obliterans occurs, and he was unable to see why it should not affect the femoral as well as the cerebral vessels. He had not, however, observed it in a peripheral artery of a limb.

DR. VAN GIESON said that he had not, except in the case referred to at the time he presented the specimen.

The Society then went into Executive Session.

Stated Meeting, September 26, 1883.

GEORGE F. SHRADY, M.D., PRESIDENT, IN THE CHAIR.

DR. GEORGE R. ELLIOTT presented a specimen of

SACCULATED ANEURISM OF THE ABDOMINAL AORTA,

accompanied by the following history: The points of interest were its occurrence in a person in whom the other organs were found in a healthy condition, the healthy appearance of the aorta above and below the aneurism, the small size of the tumor, and the absence of specific disease. Frederick M—, German, aged thirty-seven, married, and a cabinetmaker by occupation, was admitted into the New York Hospital, July 6, 1883. Family history bearing on the case was negative; alcoholic history was well marked; there was no evidence of syphilis. For eighteen months previous to admission he suffered from sudden attacks of pain in the left lumbar region, running down the course of the ureter to the testicle. These attacks varied from a few hours to several days in duration. Upon admission he was well nourished. Examination of the viscera, both thoracic and abdominal, revealed nothing abnormal; there was no marked abdominal pulsation, and no *bruit* could be heard; there was no abdominal tenderness upon palpation. For several days he continued to complain of pain above de-

scribed, together with pain at times shooting down the course of the left sciatic nerve, and often also of vague pains referred to the bladder. He continued in that condition until early on the morning of July 23d, when after some slight exertion he suddenly went into a condition of collapse attended with evident signs of internal hemorrhage, and the simultaneous development of a tumor in the left iliac region. A hard tumor could be made out by palpation, and a hypodermic syringe was introduced and blood withdrawn.

At the autopsy, made six hours after death, the left ventricle of the heart was slightly hypertrophied; in other respects the organ was normal. The other organs of the body were found in a normal condition. Behind the peritoneum on the left side of the spinal column there was seen a large clot of blood extending from the diaphragm to the sacro-iliac junction and floating up the kidney, ureter, and intestines. At a point of the abdominal aorta, one-half inch above where the coeliac axis was given off, a sacculated aneurism was found. The sac measured three inches in its longer diameter and one and one-half inch in its shorter. The tumor was found resting upon the bodies of the last three dorsal vertebrae. At the posterior inferior part of the sac on the left side there was an opening one-half inch in diameter and the parts in immediate contact were lacerated. Upon section the cavity of the aneurismal tumor contained laminated fibrin and recent blood coagula. The bodies of the tenth, eleventh, and twelfth dorsal vertebrae were found eroded but the intervertebral cartilages were quite intact.

DR. F. V. WHITE asked if the chronic alcoholism was regarded as a factor in the production of the aneurism.

DR. HEINEMAN said that alcoholism was one of the recognized causes of atheroma of the arteries.

DR. VAN GIESON said with regard to diagnosis that he had a somewhat similar case, in which there was found after death a small aneurismal tumor at the upper portion of the abdominal aorta with slight erosion of the vertebra, and the only symptom during life was a dull, heavy pain below the umbilicus that had continued for a number of months. No diagnosis had been made, although the man had been seen by several eminent physicians, and he died almost instantly. The practical point is this: when there is obscure abdominal pain, shooting through to the back, extending down the course of the ureter, and, after careful examination, all other causes can be excluded, and the patient has a history of syphilis, there is very strong presumptive evidence of aneurism. At least he had seen one such case, and made the diagnosis of probable aneurism, and, although the patient passed from his observation, Dr. Van Gieson learned subsequently that he died of aneurism.

DR. VAN SANTVOORD thought the apparently normal condition of all the other viscera would exclude alcoholism as a cause, and suggested that some local pressure from the patient's occupation would be a more probable cause.

INFARCTION AND ABSCESS OF THE SPLEEN.

DR. HEINEMAN presented a spleen which had been the seat of an old infarction, and had terminated in a large abscess—in a case of heart disease. The abscess was opened and the patient died two days later of progressive asthenia.

The patient was a male, aged twenty-one, native of Germany, single, and a waiter by occupation, who was admitted to the Mount Sinai Hospital, March 25, 1883. Family history was negative. Two years previous he had rheumatism, from which he recovered quite completely. Four months previous he was seized with pain in the left lumbar region, with pain and stiffness in both legs, most marked in the left, which continued acutely for three or four weeks. This subsided to a considerable extent, but the left lumbar pain returned with increased force three weeks ago, accompanied

by pain in the left chest. He has had no vomiting, but has suffered from thirst; his appetite has remained good. For the past fortnight he has urinated frequently and even had incontinence at times.

Upon admission, the patient was fairly nourished, had slight oedema of the left foot, pulse and respiration normal, appetite good. A loud systolic aortic and mitral murmur with a slight presystolic murmur and cardiac hypertrophy is recognized. Urine subsequently contained blood at times, but always continued to contain pus and mucus in varying amounts. The frequency of micturition continued at times. In May (two months after admission) hyaline and slightly granular casts were found, albumen was present at all times in varying amounts. The quantity of urine was at all times considerable.

After admission, the evening temperature was always slightly elevated, usually rising to 101° , and occasionally rising to 103° and even 104° . His pain in the left lumbar region continued after admission constantly, varying in amount, and gradually a fulness with tenderness upon pressure was developed over this region. Two months after admission he had distinct chills followed by febrile movement and sweating for several days. Five months after admission distinct enlargement of the spleen was apparent. Later fluctuation was recognized over the left lumbar region. Perinephritic abscess was suspected, but operation was for unavoidable reasons deferred until a month later, when an incision was made by Dr. Gerster over the lumbar region and an abscess cavity opened from which almost two quarts of bloody pus escaped. Microscopic examination showed the fluid to contain broken-down pus-globules and small broken-down round cells.

The patient, who was extremely emaciated and debilitated at the time of the operation, recovered from the immediate effects, and appeared in many ways more comfortable, but continued to fail rapidly and died September 14th, six months after admission to the hospital, and probably ten months after the beginning of his local trouble. Upon autopsy the following condition was found: Lungs, stomach, and intestines were normal. Heart dilated and hypertrophied, with large firm old vegetations upon the aortic valves, stenosis of the aortic orifice; thickening and stenosis of the mitral orifice. Liver was congested and nutmeg in appearance. Kidneys were of normal size, capsule not adherent, surface smooth and mottled, striations lost, and left kidney contained a few old decolorized infarctions. Bladder mucous membrane was inflamed and coated with pus and fibrin in places. There was slight burrowing of pus behind the left mesocolon which was evidently recent. Spleen was enormously enlarged. A large old infarction was found close to the capsule, part of which, together with the neighboring splenic tissue, had broken down into an abscess in the centre of the enlarged organ, forming a cavity six inches long, four inches wide, with old thickened walls and containing some degenerated pus. The walls were formed by the thickened capsule and adhesions with neighboring connective tissue structures and above and below by the remaining splenic tissue. The pus cavity had not ruptured and presented only the artificial opening.

Dr. Heineman remarked that abscess of the spleen after infarction from cardiac disease was of not frequent occurrence, though met with occasionally. Dr. F. Delafield had personally communicated the recital of three or four cases, in one of which the whole spleen had broken down. All these cases had terminated by rupture and the resulting peritonitis. Concerning the result in the case related, the abscess would probably also have ruptured, if it had not been opened, and had it been possible to recognize the nature of the trouble early in the disease it is not improbable that the result of surgical interference would have been more successful.

PHTHISICAL LUNG WITH PERFORATION.

Dr. Heineman also presented a lung which was removed from a patient, who had been in the service of Dr. Alfred Meyer at the Mount Sinai Hospital. The patient was taken ill two months before his death with the symptoms of acute pulmonary tuberculosis, he died September 25th, yesterday, from perforation and resulting pneumothorax. The perforation had taken place probably twenty-four hours before death. The lung presented the lesion of pneumonic phthisis, with the usual bronchitis and peribronchitis and was studded with cheesy nodules; the upper lobe was completely broken down into a single large cavity and the perforation was in the walls of this cavity. The point of interest here was perforation taking place within two months from the onset of the disease.

DR. VAN GIESON said, concerning the remarks with regard to blood and pus in the urine in cystitis tending to mask the symptoms, and to some extent to justify the diagnosis of perinephritic abscess, that in perinephritic abscess, a disease difficult to diagnose under any circumstances, the presence of pus in the urine is one of the least of the symptoms, unless there is communication between the abscess and the kidney, which is a rare complication. He would be inclined to attach but little importance to this as a symptom in perinephritic abscess.

DR. HEINEMAN: So would I.

DR. J. LEWIS SMITH said the case reminded him of an interesting one of perinephritic abscess which was finally relieved by operative measures. There was albuminuria for perhaps two or three weeks early in the sickness and afterward the urine became normal. The abscess made its way into the intestine, which fact obscured the diagnosis because the tenderness and fulness abated with the occurrence of the discharge.

UMBILICAL PHLEBITIS.

Dr. J. Lewis Smith presented a specimen removed from the body of an infant who died in the New York Infant Asylum, at the age of eight months. At birth it weighed eight pounds and six ounces, was plump and well developed, and the mother was healthy. When four or five days old it began to be feverish, one day the temperature rising to 104.3° F. There was no outward appearance of inflammation of the umbilicus, and the navel healed readily. At the age of two weeks there appeared an abscess on the scalp, one upon the back, and another upon the nates. These abscesses remained and new ones appeared as long as the child lived, showing that it suffered from septicæmia. At the age of four weeks orchitis upon one side developed and continued for three weeks, when it resolved. When the child was two months old a tumor appeared half an inch above the umbilicus, and when it had continued for a week Dr. Parker opened it, and it discharged bile instead of pus. There was no cough, but at times diarrhoea occurred. This biliary fistula closed soon after it was opened, and after that the discharge of bile occurred from the umbilicus, which continued as long as the child lived. The autopsy was made by Dr. Welch, who reported as follows: Length of infant, twenty inches; very much emaciated. There were the remains of a number of old abscesses upon the trunk and extremities. On opening an abscess on the right side of the occipital bone it was found to contain four drachms of pus, and corresponded to a carious defect in the occipital bone, one inch in length and half an inch in breadth. The dura mater immediately beneath was thickened, but the pia mater was normal. There was a small opening at the umbilicus, with a yellow margin, through which a probe passed into a cavity. The skin about the opening was normal except a small cicatrix about the umbilicus. The heart was normal. The lower parts of the lungs were congested, as also were the spleen and kidneys, the supra-renal capsules and bladder. The tunica albuginea of the left testicle was thickened. The stomach and intestines were normal. The umbilical vein was dilated to about twice

its normal size, its walls were thickened, and it contained yellow, thickened bile. One of the branches of the vein could be traced into the liver, where it opened into an abscess about the size of a walnut containing thick pus, and through this abscess a communication had been established between the umbilical vein and the bile-ducts. The gall-bladder and the hepatic and cystic ducts contained bile and appeared normal, and the liver, except for the abscess, presented a normal appearance. The abscess was in the right lobe, near the posterior border and extended to the superior surface. The umbilical vein opened at the umbilicus, from which point the probe passed into the dilated vessel, but it contained no blood. The peritoneum was normal, as also were the brain and spinal cord.

Dr. Smith regarded the case as a rare one. He had not seen a biliary fistula like this, and it had interested him that undoubted umbilical phlebitis may occur. Thrombosis occurs not infrequently with softening of the material and the formation of a fluid that presents the gross appearance of pus. Such a specimen he had presented to the Society within a year. But here there was a true umbilical phlebitis, because the walls were thickened and distended to the surface of the vein, and exhibited the appearance of an inflammatory process; while at the end of one of the branches was an abscess in the liver which established a communication between the liver and the umbilical vein, through which bile escaped.

DR. VAN GIESON asked if it was not unusual for a child to live for this length of time with secondary lesions arising from umbilical phlebitis.

DR. SMITH said he had not met with a sufficient number of cases to enable him to answer the question.

DR. FERGUSON said that some time ago he made an autopsy on the body of a child eight or nine years of age, who had been vaccinated two years previous to death. Three months after the vaccination a rash broke out over the entire surface of the body and three months subsequent to that the child complained of pains in the bones, and later on of intense pain in the head, and six weeks before admission to the hospital it was noticed that she was incapable of performing certain movements, and markedly that she was unable to move her head without moving her entire body. Shortly before admission she fell down stairs, remained in the position in which she fell, was taken up and put upon a bed, when it was found that she was only semi-conscious. After a time she gained consciousness and was removed to the hospital, and died at the end of eight or nine days. At the autopsy he found several open sores communicating with the bone beneath. On removing the brain it was found that the odontoid process projected into the foramen magnum, the ligament which was extensively diseased having broken, and had partially crushed the pons. The point of interest in the case was not so much the communication of the abscess with bones as the existence of tubercle bacilli in very large numbers, not only in the abscesses but in the bones beneath them, and in one or two isolated tubercles of the brain. One of the queries in the case was, How much did the vaccination have to do with the final condition?

The Society then went into executive session.

THE THERAPY OF SPASMUS NICTITANS.—Under this head Dr. Friedr. Betz relates the history of a boy, fourteen years of age, who had suffered for several years from a bilateral nictitating spasm of the lids. Several physicians had attempted to relieve him, but in vain. The boy was healthy, and his eyesight good. He had, however, quite long eyelashes and the edges of the lids were reddened. Betz performed epilation of numerous lashes above and below on both eyes. The result was immediately successful.—*Memorabilien*, August, 1883.

Reviews and Notices.

AN ENCYCLOPÆDIC INDEX OF MEDICINE AND SURGERY. Edited by EDWARD J. BERMINGHAM, A.M., M.D. 8vo, pp. 934. New York: Bermingham & Co. 1882.

THE plan of this book, as set forth in the preface, is excellent. The intention, as there stated, was to furnish a work that should give a comprehensive account of every disease, its etiology, symptoms, diagnosis, prognosis, and treatment, and which at the same time should consist of but one volume, thus greatly facilitating a ready reference. An account of nearly every disease known is there met with, though the cross references are not as numerous as they should be. Such common terms, for example, as Dupuytren's contraction, Menière's disease, Pott's disease, scoliosis, otitis, trichinosis, osteomalacia, trismus, and others, are not to be found. The several conditions are treated of under other headings, it is true, but in a work of this nature it is annoying to be obliged to think of all the synonyms of a disease before finding the subject wanted. Then, again, we were greatly disappointed in the articles. We had supposed that they were original articles, prepared especially for this work by the authors whose names appear in the list of contributors. But this is not the case. Some, indeed, appear to have been written expressly for this or some similar publication, but others, and among them some of the most important, are taken bodily from other sources. The articles on "Milk Fever," "Puerperal Convulsions," and "Puerperal Insanity," for example, are found word for word in the second American edition of Playfair's "Midwifery." The article on "Perityphlitis," by Dr. H. B. Sands, is an exact reprint of a lecture delivered by him before the Anatomical and Surgical Society of Brooklyn, on May 31, 1880, and published in the *Annals* for July of that year. The article on "Pneumonia" is in the form of a lecture and will have a charmingly familiar sound to those old students of the College of Physicians and Surgeons whose good fortune it was to listen to Professor Alonzo Clark. The articles are uneven, and do not bear the marks of careful editing. Nearly twenty pages are devoted to "Infantile Paralysis," while "Diseases of the Liver," are treated of in nine pages, and "Typhoid Fever" is disposed of in less than two. Of course, when there are so many different writers there must be a difference in style, but it need not be so marked as we find it here. The articles on surgical subjects written by Mr. C. B. Keetley are painfully jerky, and read very like notes jotted down by a lecturer whose memory needs to be refreshed from time to time. A succession of sentences of two and three words each is apt to weary the reader even of a condensed encyclopedia, and when the entire sentence consists of one word the shock is severe. Notwithstanding these faults of editing and compilation, there are many excellent articles to be found here, and the work is really valuable as a handy book of reference in hurried moments.

THE ROLLER BANDAGE. By WILLIAM BARTA HOPKINS, M.D., etc. With 73 illustrations. 12mo, pp. 95. Philadelphia: J. B. Lippincott & Co. 1883.

DR. HOPKINS'S little work on the roller bandage is a clear account of the various applications of that bandage to the different parts of the body, but illustrated by the most hideous drawings that can be imagined. This, however, is the fault of the book-maker. Dr. Barton has done his work well and deserves to have had better fortune with his cuts.

SEXUAL IMPOTENCE IN THE MALE. By WILLIAM A. HAMMOND, M.D. New York: Bermingham & Co. 1883.

THIS work of 274 pages is divided into four chapters, entitled, "Absence of Sexual Desire," "Absence of the

Power of Erection and of Consequent Intrmission," "Absence of the Power of Ejaculating the Seminal Fluid into the Vagina," and "Absence of the Ability to Experience Pleasure during the Act of Copulation and during the Emission of the Semen." Each of these topics is fully described and illustrated by cases drawn from the author's experience or cited from authorities, and each chapter is accompanied with therapeutic suggestions for the relief of the conditions described. Much space is given to the recital of instances of perverted sexual feelings and acts which in their results so frequently if not commonly lead to the induction of ultimate impotence. The literary style of the book is admirable, its information is instructive, and its external appearance is attractive.

Army and Navy News.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from September 29 to October 6, 1883.

TILTON, H. R., Major and Surgeon. Assigned to duty as Post Surgeon at Fort Wayne, Michigan. S. O. 183, par. 4, Department of the East, September 28, 1883.

BRECHEMIN, LOUIS, Captain and Assistant Surgeon. Relieved from duty at Fort Columbus, N. Y. H., and assigned to duty at Fort Wadsworth, N. Y. S. O. 183, par. 5, Department of the East, September 28, 1883.

Official List of Changes in the Medical Corps of the Navy, for the week ending October 6, 1883.

BEARDSLEY, G. S., Surgeon. Granted leave of absence for six months, with permission to leave the United States.

AUSTIN, A. A., Passed Assistant Surgeon. Orders to Naval Hospital, New York, revoked, and placed on waiting orders.

LIPPINCOTT, GEORGE C., Passed Assistant Surgeon. Ordered to the Naval Hospital, New York.

PECK, GEORGE, Medical Director. Detached from the Naval Hospital, Mare Island, Cal., and placed on waiting orders.

MCMURTRIE, D., Surgeon. Ordered to report at Washington, D. C., October 3d, for Medical Survey.

CRAWFORD, M. H., Passed Assistant Surgeon. Ordered to report at Washington, D. C., October 3d, for Medical Survey.

DUBOIS, F. L., Surgeon. Detached from Naval Rendezvous, Philadelphia, and ordered as member of the Medical Examining Board, Philadelphia.

RUSH, CHARLES W., Passed Assistant Surgeon. Detached from the Naval Hospital, New York, and ordered to the Receiving Ship Colorado, New York.

JONES, M. D., Passed Assistant Surgeon. Detached from the Naval Hospital, Washington, D. C., and ordered to the Naval Hospital, New York.

ASHERIDGE, RICHARD, Passed Assistant Surgeon. Detached from the Naval Academy, and ordered to the U. S. S. Swatara.

APHASIA AT THE COMMENCEMENT OF TUBERCULAR MENINGITIS.—Dr. Schutz relates the case of a man with fungoid arthritis of the elbow, who was suddenly seized with aphasia without any other paralytic symptoms. He could read and write, but was unable to pronounce a word, even if it was spoken before him. Soon other symptoms appeared, cephalalgia, facial paralysis, and periods of excitement followed by depression; then deafness, pain in the neck, strabismus, and dilatation of the pupils, followed by coma and death. The autopsy revealed tubercular meningitis. Aphasia has usually been regarded as a late, rather than an early symptom of this disease. —*L'Abeille Medicale*, September 10, 1883.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending October 9, 1883:

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Cases.								
October 2, 1883.....	0	86	26	2	11	41	0	0

SCHEDULE OF THE VARIOUS CLINICS TO BE HELD IN NEW YORK CITY THE COMING SEASON.

CLINICS IN GENERAL MEDICINE.

Monday: 11 A.M., Post-Graduate School and Bellevue Hospital; 2 P.M., New York Polyclinic; 2.30 P.M., New York Hospital; 5 P.M., Post-Graduate School.

Tuesday: 11 A.M., Post-Graduate School; 11 A.M., University Medical College; 10 A.M., Bellevue Hospital; 1.30 P.M., Bellevue Medical College; 1.30 P.M., Bellevue Hospital; 2 P.M., New York Polyclinic; 3 P.M., Bellevue Hospital.

Wednesday: 11 A.M., Woman's Medical College; 11 A.M., University Medical College; 2 P.M., New York Polyclinic; 5 P.M., Post-Graduate School.

Thursday: 10 A.M., Bellevue Medical College; 11 A.M., Post-Graduate Medical School; 12 M., College of Physicians and Surgeons; 2 P.M., Polyclinic; 2.30 P.M., New York Hospital; 5 P.M., Post-Graduate School.

Friday: 1.30 P.M., Bellevue Hospital; 2 P.M., University Medical College; 2 P.M., Polyclinic; 5 P.M., Post-Graduate School.

Saturday: 11 A.M., Post-Graduate School; 11 A.M., Bellevue Hospital; 2 P.M., Polyclinic.

GYNECOLOGICAL CLINICS.

Monday: 9 A.M., New York Polyclinic; 1 P.M., Post-Graduate School; 2 P.M., Woman's Hospital; 3 P.M., Polyclinic.

Tuesday: 9 A.M. and 3 P.M., Polyclinic.

Wednesday: 9 A.M., Polyclinic; 9 A.M., Woman's Medical College; 11 A.M., Post-Graduate School; 1 P.M., Post-Graduate School; 3 P.M., Polyclinic.

Thursday: 9 A.M., Polyclinic; 1.30 P.M., Bellevue Hospital; 3 P.M., Polyclinic.

Friday: 9 A.M., Polyclinic; 11 A.M., Woman's Medical College; 1 P.M., Post-Graduate School; 3 P.M., College of Physicians and Surgeons; 3 P.M., Polyclinic.

Saturday: 9 A.M., Polyclinic; 3 P.M., Woman's Hospital; 3 P.M., Polyclinic.

SURGICAL CLINICS.

Monday: 11 A.M., Polyclinic; 12 M., Post-Graduate School; 12 M., College of Physicians and Surgeons; 2 P.M., Bellevue Hospital.

Tuesday: 11 A.M., Polyclinic; 12 M., Post-Graduate School; 2.30 P.M., Roosevelt Hospital.

Wednesday: 10 A.M., Bellevue College; 11 A.M., Polyclinic; 12 M., Post-Graduate School; 1.30 P.M., Bellevue Hospital; 2 P.M., University Medical College; 2.30 P.M., College of Physicians and Surgeons; 3 P.M., Presbyterian Hospital.

Thursday: 11 A.M., Polyclinic; 12 M., Post-Graduate School; 2 P.M., New York Hospital; 2.30 P.M., Bellevue Hospital.

Friday: 11 A.M., Polyclinic; 12 M., Post-Graduate School; 3 P.M., Bellevue Hospital.

Saturday: 11 A.M., Polyclinic; 12 M., Post-Graduate School; 12 M., Woman's Medical Hospital; 12 M., University Medical College; 1.30 P.M., Bellevue Hospital; 2.30 P.M., New York Hospital; 2.30 P.M., Presbyterian Hospital.

EYE AND EAR CLINICS.

Monday: 1.30 P.M., Bellevue Medical Hospital; 2 P.M., Polyclinic; 2.30 P.M., Manhattan Eye and Ear Hospital; 4 P.M., Post-Graduate Medical School.

Tuesday: 1 P.M., Post-Graduate School; 2.30 P.M., Post-Graduate School; 2 P.M., University Medical College; 2 P.M., Polyclinic; 3 P.M., College of Physicians and Surgeons.

Wednesday: 2 P.M., Polyclinic; 2.30 P.M., Manhattan Eye and Ear Hospital; 3 P.M., New York Eye and Ear Infirmary; 4 P.M., Post-Graduate School.

Thursday: 1 P.M., Post-Graduate School; 2 P.M., Polyclinic; 2.30 P.M., Post-Graduate School.

Friday: 2 P.M., Polyclinic; 2.30 P.M., Manhattan Eye and Ear Hospital; 4 P.M., Post-Graduate School.

Saturday: 1 P.M., Post-Graduate School; 2 P.M., Polyclinic; 2.30 P.M., Post-Graduate School; 2 P.M., Woman's Medical College.

CLINICS FOR NERVOUS AND MENTAL DISEASES.

Monday: 1 P.M., Polyclinic; 4 P.M., Post-Graduate School.

Tuesday: 1 P.M., Polyclinic; 1.30 P.M., Manhattan Eye and Ear Hospital; 4 P.M., Post-Graduate School.

Wednesday: 1 P.M., Polyclinic; 4 P.M., Post-Graduate School; 4 P.M., Manhattan Eye and Ear Hospital.

Thursday: 1 P.M., Polyclinic; 2 P.M., University Medical College; 1.30 P.M., Manhattan Eye and Ear Hospital; 4 P.M., Post-Graduate School.

Friday: 1 P.M., Polyclinic; 4 P.M., Post-Graduate School; 4 P.M., Woman's Medical College.

Saturday: 1 P.M., Polyclinic; 3 P.M., College of Physicians and Surgeons; 4 P.M., Post-Graduate School.

CLINICS FOR DISEASES OF CHILDREN.

Monday: 10 A.M., Post-Graduate School; 10 A.M., Polyclinic; 1.30 P.M., Bellevue Medical College; 2.30 P.M., Bellevue Hospital.

Tuesday: 10 A.M., Post-Graduate School and Polyclinic; 3 P.M., New York Hospital (out-door department); 5 P.M., Post-Graduate School.

Wednesday: 10 A.M., Post-Graduate School and Polyclinic; 1.30 P.M., College of Physicians and Surgeons.

Thursday: 10 A.M., Post-Graduate School, Polyclinic, and University Medical College; 11 A.M., Woman's Medical College.

Friday: 10 A.M., Post-Graduate School and Polyclinic; 2 P.M., New York Hospital (out-door department).

Saturday: 10 A.M., Post-Graduate School and Polyclinic; 5 P.M., Post-Graduate School.

CLINICS FOR SKIN AND VENEREAL DISEASES.

Monday: 1 P.M., Polyclinic; 3 P.M., College of Physicians and Surgeons (skin).

Tuesday: 1 P.M., Polyclinic; 5 P.M., Post-Graduate School (skin); 7 P.M., Post-Graduate School (venereal).

Wednesday: 1 P.M., Polyclinic; 1.30 P.M., Charity Hospital (venereal).

Thursday: 1 P.M., Polyclinic; 3 P.M., College of Physicians and Surgeons (genito-urinary); 5 P.M., Post-Graduate School (skin); 7 P.M., Post-Graduate School (venereal).

Friday: 1 P.M., Polyclinic.

Saturday: 1 P.M., Polyclinic; 5 P.M., Post-Graduate School (skin).

CLINICS FOR DISEASES OF THROAT AND NOSE.

Daily: 2.30 P.M., Post-Graduate School; 4 P.M., Polyclinic.

Tuesday: 2 P.M., College of Physicians and Surgeons.

THE CIRCULAR LETTER TO THE FELLOWS OF THE NEW YORK ACADEMY OF MEDICINE CONCERNING PROPOSED AMENDMENTS IN THE CONSTITUTION AND BY-LAWS OF THAT BODY.—Dear Doctor: I assume that every Fellow of the New York Academy of Medicine must regard it as a most unfortunate event that anything should occur to interrupt its fraternal harmony, its useful work, and its progressive growth. While we cannot shut our eyes to the fact that this is the present condition of the Academy, it would be both useless and unwise to discuss the causes which have brought about this state of things, because, from their nature, they involve questions on which the most able, the most loyal, and the most conscientious men in the profession honestly differ. Let us accept this fact as inevitable, and that the Academy can do nothing which will effectively advance the interests of the profession by way of discussions, which irritate, but do not change convictions, or by arbitrary regulations, secured by shrewd tactics, but which carry no moral force. The Academy of Medicine is not fulfilling its mission when it is engaged in warm discussions of questions of casuistry, in polemical controversies, or in medical politics. The *Ephemeris* of Dr. Squibb quotes with approval an editorial from the *Boston Medical and Surgical Journal*, which contains the following sentence: "The lesson also is so obvious that he who runs may read, that the more our Societies confine themselves to their proper field—the joint cultivation of medical science and good-fellowship—and the less they meddle with medical politics, the better will it be for their own future and the common good of the profession." It seems to me that the truth of the above sentiment has been unfortunately, but clearly, demonstrated by our Academy of Medicine. The question which we have now to meet is: What measures can be taken to secure for the Academy a return of its prosperity? by which I mean a restoration of its fraternal harmony and good-fellowship; a renewal of its active scientific work; an increase of its funds for the growth of its library and the adequate support of its journal department. Since our last meeting this question must have occupied the minds of all our Fellows, who appreciate the importance of the Academy, which should represent the highest scientific work of the profession of this city. All must feel that the character of the profession and the grade of individual reputation is deeply involved in a wise settlement of this question. I trust that no one will suspect me of a wish to force my individual views upon the Academy, but that, in consideration of the experience which I have had in its affairs, each will understand the spirit in which I venture to offer a few suggestions to be discussed, amended, or improved at our first meeting in October. I do not feel it necessary to apologize for expressing the hope and the belief that every Fellow of the Academy who feels a proper sense of his personal responsibility, and what he owes to the profession and the public, will be present, and contribute by his voice or his vote to a satisfactory adjustment of our present difficulties. It must be obvious to all, that to attain this end we must make a new departure on certain questions, to which it is unnecessary to refer more definitely. There is an "irrepressible conflict" of views and opinions which cannot be settled by parliamentary tactics or a majority of votes, but must continue until in the progress of time the moral sentiment of the profession is crystallized in a public opinion which will have the force of law. No possible good can come from profitless and irritating discussions of these questions in the Academy of Medicine. It therefore seems to me of vital importance that now, in making a new departure, everything in relation to them should be buried in the past and forgotten. No unhappy dif-

ferences can be settled, no principle or cause can be advanced, no society or individual can be benefited by keeping up a galling wakefulness and feeding the living ulcer of a corroding memory of the past. The anodyne draught of oblivion is the first specific remedy for healing such ills as those under which the Academy is now suffering. The next point to be secured is such a change in our organic laws as to make it impossible that trouble and danger can ever again occur in the Academy. At our first meeting in October, certain amendments to the constitution and by-laws will be proposed for discussion, and at the following meeting they will be submitted to the vote of the Academy. Every change proposed has been the result of a most careful study of the subject, and has a distinct purpose which will be obvious to all. I think that it will be apparent that the whole intent of the proposed amendments is to make the Academy of Medicine a purely scientific society, independent of all other organizations; to place its standard of ethics on a higher plane than before; and to prevent the possibility of any future troubles by the introduction of matters foreign to its avowed objects. Respectfully submitting the above suggestions to your candid consideration, I remain, very sincerely yours, FORDYCE BARKER.

THE OTHER SIDE OF THE QUESTION, AS PRESENTED BY THE COUNCIL FOR UPHOLDING THE NATIONAL CODE.—Dear Doctor: The Council of the Organization for Upholding the National Code of Medical Ethics in the State of New York, begs to call your attention to a circular recently issued in which are proposed certain amendments to the constitution and by-laws of the New York Academy of Medicine. The Council cannot but regret the issuing of this circular as a covert movement, under a plea for harmony, in behalf of the organized effort in opposition to the National Code of Ethics. The proposed amendments, were they adopted, would eliminate from the constitution and by-laws everything relating to ethics, and surrender the Academy to those who advocate the abolition of all ethical codes. The Academy would thereby be deprived of the right of representation in the American Medical Association, and of affiliation with other medical organizations out of the State of New York. It may be assumed that there is no disposition on the part of those who are for upholding the National Code of Ethics to raise any discussion respecting the Code in the Academy. The Code has never been made a subject of discussion in the Academy by any one in favor of upholding it, and there is no ground for the supposition that it ever will be, unless it becomes necessary in the way of defence. The resolutions presented and adopted at the last meeting of the Academy had for their object the prevention of any future discussion relating to the Code. Every true friend of the Academy is earnestly requested to attend its meetings in order to resist the introduction of discussions and controversies in relation to ethics, by simply maintaining, in their integrity, the time-honored constitution and by-laws of this institution, to which it owes its origin and prosperity. Abram DuBois, Austin Flint, Austin Flint, Jr., J. W. S. Gouley, John H. Hinton, Samuel T. Hubbard, Wm. T. Lusk, Samuel S. Purple, T. Gaillard Thomas, *Council*.

DIABETES AND THE BROMIDE OF POTASSIUM.—French therapeutists are still debating the question of the value of bromide of potassium in diabetes. According to a recent communication to the Académie de Médecine, bromide of potassium forms a good adjuvant in certain cases, but as it has a very depressive effect on the system it should only be used concurrently with other remedies which would raise the tone of the constitution. M. Bouchardat agreed with this view. He believed that the salt in question was useful in certain cases, but should be used with prudence. He thought that preference should be given to *régime* and gymnastic exercises. M. Lanier said that in the cases of children and the aged bromide of potassium should not be used. M.

Hardy could not adopt the views of his colleague; he obtained very good results from the bromide in diabetes. He gave it in the dose of a drachm daily, and instead of the strength of the patient diminishing under its influence, it increased. The opinion of your correspondent, who has had the opportunity of using it in this malady, is that it certainly is of great use, as it effectually calms the great agitation of the patient, especially at night, when the great thirst prevents sleep.

TYPHOID FEVER AND ETHER.—A French physician has published five cases of typhoid fever treated by subcutaneous injections of ether, which he considers as the best mode of administering stimulants in the adynamic forms of the disease. Two injections, of twenty drops each time, were made daily, and under its influence the patient was aroused and delirium ceased. In pneumonia, these injections are of the greatest utility, as they are in every malady assuming a typhoid form.

A THERAPEUTIC SUMMARY.—The following notes by Dr. Ad. Vomáčka, of Leitmeritz, give, in a very condensed form, some of the suggestions and additions which have been made of late to therapeutical literature:

Typhoid fever.—Tinct. iodin., 0.5; glycerin., acid. carbolic., āā gtt. 5; tinct. iatanh., 10.0. Give 5 to 10 drops every one or two hours, in tea or coffee.

Alcoholism.—At the beginning give hypodermic injections of sulphate of strychnine, 0.005 per dose. Internally give several times daily 4.0 to 8.0 of tincture strychni. As a prophylactic put a small amount of strychnine in the whiskey.

Anorexia.—Give pepsin, with potassium phosphate.

Asthma.—Potassium iodid., 20.0; vini, 180.0; syr. aurant., 20.0. Sig.—one-half teaspoonful three times a day. After some days increase to one teaspoonful; continue for two or three weeks, then gradually decrease.

Ascariides in children.—Sem. cucurbitæ decoct., 30.0; aquæ aur. fl., 3.0; mel. dp., 30.0. Give twice in the morning, then a dose, 15.0, of castor-oil.

Condyloma of the penis.—Wash with salt water, then powder with calomel; corrosive sublimate forms in small amounts, causing the condyloma to decrease.

Diabetes mellitus.—Solution of bromide of arsenic is to be given in doses of one drop in a glassful of water. This dose is gradually increased to three drops three times a day, always in the same amount of water. The urine is to be constantly examined. When the amount of sugar is decreased, as usually happens in about fourteen days, then decrease the arsenic to one-drop dose again. This can be kept up for years. Extreme attention need not be paid to the diet, but ordinary care as regards acids, starchy and sweet food should be taken. The greatest enemy of the diabetic is bad air, the air of chambers. Fresh air is most essential.

Chronic diarrhœa.—Zinci oxid., 3.5; sodæ bicarb., 0.5. Divide in four powders, and give one every three hours.

Diphtheria.—Potassium iodid., potassium chlorat., āā 4.0; aquæ, 100.0. Give one teaspoonful every half hour to children under five years of age, two teaspoonfuls to children under ten years of age.

Dysentery.—Decoct. quiniæ, 200.0; potass. chlorat., 4.0. Use in twenty-four hours.

Epilepsy.—Sodii bromid., ammon. bromid., āā 10.0; aquæ, 300.0. Give four to eight tablespoonfuls per dose in infusion of valerian. As supplementary give extract belladonnæ, zinci oxid., āā 1.0. Div. in pil. No. 40. Give about four pills daily. Keep the bowels open.

Gonorrhœa.—Injections of chloral hydrat., 3 to 250 of water, twice daily. Internally, potassium chlorate, 3.0 per dose.

Whooping-cough.—Olei terebinth., 10.0; syr. althææ, 80.0. One teaspoonful every three hours. Children between one and a half and four years of age may be given five to eight drops of tincture of eucalyptus in sugar-water, every three hours, or tinct. eucalyptus, 3.0; glycerin, syr. simpl., āā 15.0; aquæ, 100.0. One teaspoon-

ful every three hours. Cure may be expected in three or four weeks.

Phthisis.—Give twice daily, by an inhalation apparatus, twenty drops of a mixture equal parts creasote and chloroform dropped upon a sponge. Internally iron (?), quinine, hypophosphites, and cod-liver oil.

Insomnia.—Cannabium tannicum.

Syphilis.—As a substitute for mercury : 0.3 bichromate of potassium in 600 parts of carbonic acid water.

Chronic rheumatism.—Pulv. capsici annui, 8.0 ; adipis, 30.0. Rub upon the affected part for ten minutes with the gloved hand.

Warts.—Burning with sodium æthyl. Hemorrhoids, bleeding, iodoform suppositories, 1 to 20. Fifteen suppositories ought to be sufficient.

Vomiting of pregnancy.—I. Potas. bicarb., 5.0 ; potass. bromid., 20.0 ; aquæ, 60.0.—II. Acid. citric., 4.0 ; syrup., 4.0 ; aquæ, 120.0.—A teaspoonful of I., and a tablespoonful of II. mixed, and drink effervescing every half hour.

REMARKABLE FECUNDITY.—Dr. F. P. Atkinson writes to the *British Medical Journal* as follows : "I have just come across a somewhat remarkable, well-authenticated instance of fecundity. The lady, who was of good position, married at sixteen years of age and died at sixty-four. She had thirty-nine children (all by the same husband, whom she survived) thirty-two daughters and seven sons, and they were all single births except two, which were twins. An interesting point is that all the children lived to attain their majority."

FUMIGANT MIXTURE AGAINST MOSQUITOES.—Munch, in *L'Union Médicale*, vouches for the efficacy of the following :

R. Pulv. potas. nitrat. 30 grammes.
Acid. carbolic 20 "
Pulv. insecticide (Persian) . . . 125 "
Pulv. carbon. lig. 250 "
Gum tragacanth q. s.

FRENCH HOSPITALS.—A recent inquiry made by the Bureau of Public Assistance shows that there are at the present time in France 1,563 hospitals and asylums of all kinds, giving a proportion of one establishment for every 24,000 inhabitants. The officials and *personnel* of all these amount to 28,676 persons, viz., 2,787 physicians and surgeons, 3,050 dressers and hospital attendants, 11,286 on the religious staff, and 11,553 servants. The number of beds in the 1,563 establishments is 164,955, of which 71,192 are at the service of the sick, 54,245 for incurables and infirm patients, 16,050 for children, while 23,459 are reserved for those engaged on the nursing staff. With regard to ordinary cases, the number of patients admitted amounts to about 360,000 every year, with an average of 40,000 for special treatment. In general the proportion of admissions into the hospitals are 90 to every 10,000 inhabitants.

HOSPITAL ACCOMMODATION ON THE CONTINENT.—An article in the *Journal de Statistique Suisse* gives the following figures respecting the number of beds in proportion to the inhabitants in some of the countries of Europe, from which it appears that Switzerland is the best furnished with accommodation in this respect. The statistics are as follows :

Country.	Population.	Number of beds.	Number of inhabitants per bed.
Switzerland	2,846,102	17,757	160
Wurtemberg	1,881,505	8,814	213
France	37,672,048	140,000	269
Hesse	884,218	1,975	448
Austria	21,747,069	38,251	569

Lunatic asylums or hospitals for the insane are not comprised in these figures. Switzerland contains fourteen of these establishments, which between 1877 and 1881 re-

ceived 7,700 patients, of whom 4,044 were men and 3,656 were women, an average of about 1,540 new patients per year. Of this number the mental condition of 21.31 per cent. of the men and 2.81 of the women could be directly traced to the abuse of alcohol.

A RARE FORM OF IMPERFORATE ANUS.—Dr. Hattie A. Galentin, of Cleveland, O., communicates the following : "In THE MEDICAL RECORD of July 28, 1883, is epitomized a case of imperforate anus very similar to one which occurred in my own practice a few months since. When first brought to my office on March 28, 1883, the child, a female, was five months old, large, and apparently healthy. The mother stated that its bowels had not moved for nearly two weeks. I prescribed hydrargyrum cum creta, to be followed by a large dose of castor-oil. Two days later, no evacuation having occurred, a soapsuds injection was ordered. The mother declaring it impossible to pass the smallest nozzle of a Davidson's syringe, I examined, and found the perineum a perfectly plain surface, the point where the anus should be marked only by the usual pigmentation. Halfway between this point and the posterior commissure, in the median line, was a fistulous opening one-eighth inch in diameter. The mother said the child's bowels had always been regular till two weeks before. I introduced a small French soft catheter and injected through it sufficient water to liquefy a large quantity of fecal matter, which was discharged through the fistula, to the evident relief of the child, who had been making vigorous, though unsuccessful efforts to empty the bowel. Four days later I operated, having in the meantime used several injections through the catheter, and thus emptied the bowel of a large accumulation. The fistula was an inch in length and nearly straight. A probe, bent at a right angle, when passed through it, presented at the point where the anus should have been, and could be distinctly felt through the thick skin closing the bowel. I cut down upon the probe point, passed a director through the fistula and out of the opening just made, and cut through the tissues as in an ordinary case of complete fistula, completely dividing the sphincter. The bleeding, which was profuse, was controlled by ferri persulph., the bowel washed out with carbolized water, and two laminaria tents left in the wound. Six hours later, the laminaria tents refusing to stay in place, tupelo tents were substituted and gave perfect satisfaction. After two days dilatation the wound was permitted to heal. The operation was followed by no fever, no inflammation, no disturbance of any kind, and *no incontinence*. The fistula healed nicely, the artificial anus proved ample, and no trouble has since been experienced. The remarkable point in this case is that until the child was four and one-half months old, the malformation gave rise to no inconvenience ; indeed, it was not known to exist, the parents regarding the mouth of the fistula as a very small anus 'in the wrong place.' And that so small a fistula should have proved adequate for so long a time is truly surprising. Only when the child began to take solid food did symptoms appear. The fistula must have been completely formed during foetal life, as meconium was passed soon after birth."

NEW USES FOR THE THERMOMETER.—Dr. J. T. Welch, of Keyport, N. J., writes : "Being called to prescribe for a patient living in the hills above Keyport, who had long been afflicted with epilepsy, and whose mind was now somewhat impaired, I noticed a remarkable pallor of countenance and that the surface of the body was very cold to the touch, so produced a clinical thermometer to ascertain the temperature. The young man evidently looked upon it as a part of the treatment, and further impressed by the admiring awe of his relatives, closed his lips upon it with as pious a care as though it had been Tyndall's prayer-gauge, and speedily seemed oblivious of all earthly things. So rapt was he that when I went to withdraw the thermometer he gave a

start like one rudely assailed. 'How did it affect you?' queried I. 'Very well indeed,' he replied; 'I think it has made me feel much better.' And then, raising his hand with an air of benediction, he added, 'It had such a quieting influence.' An hour afterward I visited a young domestic in another family, who was convalescing from a mild attack of typhoid fever, where the temperature had ranged from 100° to 102° for several days. While here I related the above incident to her employers, who laughed heartily, but the girl, with a look of scornful superiority, cried out, 'Pooh! he mustn't ever have seen one before! why, I have had two at a time in my mouth, and thought nothing of it.' 'Why was that?' asked I. 'When I was on Randall's Island.' 'Yes, but why? what were two used for?' 'Because—because,' blurted she in confusion, 'my fever was so high they couldn't tell it all on one!'

THE DISEASE OF THE MONEY COUNTERS.—A Washington correspondent visiting the Treasury Department, noticed that many of the women employed in counting bank-notes looked ill and had sores upon their hands or heads. The superintendent gave the following account of the trouble: "Very few," he said, "who spend any considerable time in counting money escape the sores. They generally appear first on their hands, but frequently they break out on the head, and sometimes the eyes are affected. We can do nothing to prevent this. All of the ladies take the greatest care of themselves in their work, but sooner or later they are afflicted with sores. The direct cause of the sores is the arsenic employed in the manufacture of the money. If the skin is the least abraded, and the arsenic gets under the flesh, a sore will appear the next morning. The habit that every one has of putting the hand to the head and face is the way the arsenic-poisoning is carried to those portions of the body. See here," said Mr. Rodgers, stopping by the side of a young lady, and picking up a glass vessel containing a sponge, "this sponge is wet, and is used to moisten the fingers while counting the money. You see how black it is. That's arsenic. Every morning a new piece of sponge is placed on the desk of each employe, but before the day is over it is as black as this. I have known half a dozen cases where ladies have been compelled to resign their positions. There are three ladies who were here six years before they were afflicted with sores. About three months ago they were so visited by them that they had to quit work. They have been away ever since, and the physician's certificate in each case says that their blood is poisoned with arsenic."

"FOR THE ARREST OF NASAL HEMORRHAGE," writes Dr. Lewis, in the *Polyclinic*, "I know of no device so good as one that may be readily extemporized with a strong piece of cord and some small pieces of sponge. The cord is tied securely to a piece of sponge, cut rounded, and just large enough to be forced backward through the nostril. Then a number of similar pieces of sponge, with a hole through the centre of each, are threaded successively on the cord. The sponge on the end of the cord is then pushed, with a probe or dressing forceps, through the nostril, quite back to the faucial orifice; and the rest of the threaded pieces of sponge are slid back, one at a time, until the nares is tightly filled. When the patient becomes secure against a repetition of hemorrhage the plugging is readily removed, one piece of sponge being withdrawn at a time, with the dressing forceps. The posterior nares may also be easily plugged by introducing either a slender gum bougie or a piece of thick catgut string, with a cord attached, through the nares, catching one end of it in the fauces with forceps, and drawing it forward through the mouth. To the cord which follows a piece of sponge or pledget of lint is tied, to be drawn up into the posterior nares. A method of making unobnoxious and painless pressure within the nares, in cases of obstinate epistaxis, is by a piece of the intestine of a chicken or other small animal, about twelve inches long,

partially filled with either air or water. One end of the intestine is, while empty and collapsed, pushed backward through the nares; when thus lodged the air or water in the other end is forced, by compression with the hand from the pendulous portion, into the part lodged in the nares. Strong, equable compression can thus be made, rendering hemorrhage impossible."

MARRIAGE AND MORTALITY.—Dr. William Pratt writes concerning this subject: "Take the male sex, and it is seen that from twenty-five to thirty years of age, 1,000 married men furnish 6 deaths; 1,000 bachelors furnish 10 deaths; 1,000 widowers furnish 22 deaths. The figures, however, become very unfavorable if the marriage be contracted before twenty. Out of 8,000 young men married before twenty, their mortality has been found to be, before marriage, only 7 per 1,000; after marriage, 50 per 1,000. With respect to the female sex we find a similar advantage of marriage over celibacy, but on the same condition. If young girls be turned into wives before twenty a like mortality befalls them which befalls the other sex. Everywhere young married people from eighteen to twenty years of age die as fast as old people from sixty to seventy years of age. The common sense and common law of Western Europe have with perfect justice marked twenty-one as the age of maturity. After that epoch, however, marriage should be contracted as soon as practicable. It is the healthiest and the happiest life; the best for the individual and for the community."

MULTIPLE SARCOMATA.—Our Cincinnati correspondent writes: "In the City Hospital, under the care of Dr. Rathaker, is a case remarkable for the number of sarcomatous tumors or nodules present. Five hundred and sixty-eight nodules have been counted that project above the surrounding surface. The nodules vary in size from a pea to a walnut. The patient is a white man, native of this city, fifty years of age. He is not emaciated, and has no great amount of pain. Some of the tumors are somewhat painful when handled. Some of them are pigmented, but the great majority are uncolored, a very few are ulcerated. The man also has a large sarcocele. The patient last winter had a nœvus (at least that was the diagnosis then) removed from his back, since which time these nodules have made their appearance. The patient has no general pigmentation of surface. Dr. Rathaker intends to publish a full report of the case." Another remarkable case was reported last year by Dr. Wm. H. Talls, of this city. It was a case of general melanosis, originating from, or preceded by a melanotic sarcoma. The patient before his death became very dark, or black, not only the skin, but the brain, internal organs, etc., being deeply pigmented.

DR. GEO. HAMILTON TO DR. CARROLL.—Dr. Geo. Hamilton, of Philadelphia Pa., writes: "I was not a little surprised and mortified on reading in your last issue the note of Dr. Alfred L. Carroll, objecting to the manner in which I had replied to his critique upon my views in regard to the subject of sewer-gas, contaminated water, etc., in the production of typhoid fever and, incidentally, diphtheria and scarlet fever, as expressed in a lecture before the College of Physicians of this city. On referring at once to the paragraph to which Dr. Carroll has called my attention, I was mortified to find that his imputation was well founded. In the second column of his paper, in *THE RECORD* of June 9th, one-third from the top, occur these words: "Very few physicians in this country have cared to learn," whilst in my paper *the*, instead of this, appears, and thus changes the meaning of the sentence entirely. A too hasty habit in reading and writing can alone account for this error, and I regret that the absence of Dr. C. from the country did not admit of an earlier correction. It is possible that a few words, more or less, may have been used in a quotation, if so, they have escaped my observation."

FURTHER INVESTIGATIONS INTO THE NATURE OF EQUINE SCARLATINA,

AND THE USE OF EQUINE VIRUS AS A PROTECTIVE AGENT.

By J. W. STICKLER, M.D.,
ORANGE, N. J.

SINCE May 1, 1883, I have inoculated with human scarlatinal virus two colts and one calf, with the following results: First colt, about one year old, in good condition; not having a discharge from either nostril; visible mucous membranes normal in appearance; rectal temperature before inoculation $101\frac{1}{4}^{\circ}$ F.; after throwing the animal I injected into its right jugular vein about thirty drops of the fluid portion of some blood abstracted from a patient having scarlatina simplex. I also introduced under the skin of the thorax a blood-clot from the same patient, and caused the colt to swallow about two drachms of pharyngeal mucus. The temperature gradually rose till it reached $102\frac{1}{2}^{\circ}$ F. (May 12th). Other than the elevation of temperature there was nothing abnormal noticeable; but during the night of May 12th the colt lacerated the skin, just inside the elbow, and at 11.30 A.M., May 13th, the temperature was $102\frac{3}{4}^{\circ}$ F.; May 14th, 8 A.M., temperature $103\frac{1}{2}^{\circ}$ F. The temperature then began to fall and reached $101\frac{1}{4}^{\circ}$ F., May 16th, 3 P.M. The inter-maxillary glands were somewhat enlarged and sensitive; the mucous membrane of nose and eyes injected, and from the nostrils there was a discharge ofropy mucus. Thinking that the inflammation resulting from the injury might possibly have masked some of the symptoms due to the action of the virus, I again injected (May 19th) into the jugular vein some pharyngeal mucus from two well-marked cases of scarlatina (both children). The only effect seemed to be an increased redness of the mucous membranes of the nose and mouth, *i.e.*, an intensifying of the redness which was developed after the first inoculation. There was a slight sore throat, which disappeared with the fading of the redness of the mucous membranes. The symptoms enumerated had almost entirely disappeared by May 24th. There was no subsequent oedema of the extremities or sheath, neither was there any desquamation of the cuticle or mucous membranes that I could discover. The rectal temperature of the calf before inoculation was $101\frac{1}{2}^{\circ}$ F.; the condition of the animal was in every particular good. Human scarlatinal blood was injected into the general circulation, and under the skin of the abdomen. After a few hours had elapsed the skin at and near the point of inoculation became uniformly reddened and somewhat sensitive to pressure. There was no systemic disturbance, save a very slight elevation of temperature. The redness and sensitiveness of the skin increased till May 24th, when I discovered pus at about the centre of the area of redness. The temperature at that time was $102\frac{1}{2}^{\circ}$ F. The mucous membranes were not affected; no enlargement of the lymphatics; recovery was complete by June 1st. Second colt, one year old. Her temperature for four successive days before inoculation was as follows: June 18th, $101\frac{3}{4}^{\circ}$ F.; June 19th, $101\frac{3}{4}^{\circ}$ F.; June 20th, $101\frac{3}{4}^{\circ}$ F.; June 21st, $101\frac{3}{4}^{\circ}$ F. The colt was perfectly well, so far as could be determined by a careful

examination. June 28th, enveloped her head in a bag, containing a chemise worn by a scarlet-fever patient. This I allowed to remain adjusted about seventy-two hours; July 2d, injected into left jugular vein, and into vein of leg some human scarlatinal blood; July 9th, introduced under skin of abdomen some epidermal scales from a scarlet-fever patient. Within forty-eight hours after the first inoculation (July 2d) the temperature began to rise, the colt became less active, showing a disposition to keep quiet. On the sixth day she began to cough slightly at intervals, and although the appetite was good, there was difficulty in swallowing. The visible mucous membranes were quite red, and at certain points they had somewhat the appearance of the mucous membrane of the pharynx in man when affected by scarlet fever. The inter-maxillary glands were enlarged and sensitive, and when the throat was pressed upon, the colt evinced uneasiness. There was a discharge of tenacious mucus from the nostrils. An examination of the interior of the pharynx revealed an unusual redness.

During the time the throat was sore and the mucous membranes affected, the temperature ranged between $101\frac{3}{4}^{\circ}$ F. and 103° F. In this case there was a desquamation of the skin at a few points where I had not previously seen any eruption. There was no swelling of the extremities or any symptoms of renal complications. Dr. Fenner, a veterinary surgeon of long experience, saw the first colt when she presented the symptoms already given, and he pronounced it a case of scarlatina similar to mild cases he had seen in his own practice. Dr. Hawk also saw her at about the same time, but was less positive in relation to the significance of the symptoms. He stated that he had seen many cases of what he regarded as true equine scarlatina. Drs. Lyon and Corliss saw the second colt. Dr. Lyon said it was a case of equine scarlatina, the symptoms being due to the action of the human virus which had been introduced into the blood. He believes in the existence of the disease (scarlatina) in the horse, and gives me the following history of a case he treated not long since: He was called on Monday to see a gelding, eight years of age, having enlarged submaxillary glands, sore throat, and elevation of temperature. On Tuesday the hair and skin of face, neck, and shoulders were found to be elevated at intervals, forming papules which could be felt with the fingers. The soreness of the throat was more intense on Tuesday, and a bright scarlet eruption was seen upon the mucous membrane of the septum nasi. During Wednesday the rash disappeared and the soreness of the throat became less troublesome. There was a discharge of mucopurulent matter from the nose. The temperature ranged between 103° F. and 106° F., and the pulse between 60 and 70. After the eruption had entirely receded, the skin began to desquamate, and it was with difficulty that the groom could cleanse the animal so as to make him presentable. There was developed afterward dropsical swellings of the sheath and extremities. Dr. Corliss, who saw the last colt, was somewhat doubtful about the condition, thinking that it might not be a specific lesion: he had never in his own practice treated what he felt confident was equine scarlatina.

I have also inoculated several children during the last summer, all of whom had been, and were at the time of inoculation exposed to the influence of air contaminated by the breath and exhalations of a scarlatinal patient. In the following instance the child had been in constant

companionship with her sister, who had scarlet fever, for five days, sleeping with her at night. I inoculated the healthy child in the arm, and notwithstanding she was not isolated, but allowed to remain in the same room with her sick sister, she did not develop the disease. In the next four cases the source of contagion was a child aged about five years, who was allowed to remain in a room in which her three brothers and sister were continually playing. I inoculated the four children at the same time, after which they were allowed to remain exposed to the contagion. Within the first twenty-four hours the two oldest developed scarlet fever, and within the next twenty-four hours the remaining two contracted the disease. On April 18th I inoculated two brothers, aged respectively seven and three and one-half years; they had been exposed several days, but neither one contracted the disease.

In both these cases there was considerable inflammation about the point of puncture, and in one quite free suppuration supervened. The next four cases were inoculated after an exposure of two or three days. The youngest child, about ten days after vaccination, began to show signs of a general systemic disturbance, *i.e.*, vomiting, impaired appetite, restlessness, and slight fever. In a few hours an eruption, characteristic of scarlatina, developed, beginning at point of inoculation and spreading uniformly over the body and extremities. There was neither sore throat nor headache in this case, and no albuminuria afterward. The next two had an eruption upon the neck, trunk, and extremities, but no vomiting or sore throat, and but very slight rise of temperature. The skin in each case desquamated in small scales after the disappearance of the eruption. Not one of the cases was confined to bed from the time of inoculation till complete restoration to health. The fourth child escaped without any disturbance, except that due to the action of the virus (locally). The last two children I inoculated had been playing in the same room with a sister who had scarlatina anginosa. The duration of exposure had probably been about three days. Five hours after being vaccinated one of the girls developed scarlatina simplex, and at the expiration of about five days the second child contracted the disease. Both these cases were followed by albuminuria, although they made a good recovery. Having carefully considered these results I am inclined to form one of two opinions, namely, that the virus used did not have any protective power, or that in the unsuccessful cases the failures were due to a pre-existing state of impregnation of the system with the human scarlatinal poison. Some of the first cases I inoculated (already reported) have been exposed to scarlet fever through the influence of air more or less charged with the specific infecting principle, and yet they have escaped the disease. It is no doubt true that some persons have but a slight predisposition, and the absence of the disease in some of the instances might be explained on that basis. I have also learned that human scarlatinal blood, even when taken from a patient having quite a severe type of the disease, does not necessarily induce the disease, or cause death when injected under the skin of the rabbit or other lower animals, and I reason from this fact that the most satisfactory way to determine whether a person has been protected by inoculation against scarlet fever, is to expose the person to the influence of the poison as it operates through the media which are supposed generally to convey it from the affected to the healthy, *i.e.*, by means of the air, fine epidermal scales, etc. John C. Peters, M.D., has written a series of articles in the *Sanitarian*, concerning the literature of equine scarlatina, and a perusal of them will disclose the fact that the disease has been recognized and described by various veterinarians who are believed to be reliable in their statements.

George Armitage, D.V.S., describes two forms of the disease, scarlatina simplex and scarlatina anginosa. He states that the simple variety usually makes its appear-

ance after an attack of influenza, "so called," has existed some days, or it may appear in an animal hitherto apparently free from the disease named. It consists of a number of blotches affecting the skin of the body, face, neck, and legs, which give rise to scarcely any swelling but cause the hair to stand erect and staring. Those parts covered with loose, thin skin, and having little hair, have rounded pimples which may be distinctly felt as well as seen. The legs swell and cause stiffness in some instances, but they are not always affected. The nasal membrane is also studded with scarlet spots having no uniformity in size, but which shortly give rise to a thin, serous discharge, subsequently changing to a yellowish or brownish color; occasionally these spots are confined to one nostril, and may constitute the whole of the outward signs, neither eruption nor swelling of the limbs being present. Soreness of the throat is evident, which sometimes creates inconvenience by causing the animal to leave off feeding. The scarlet spots gradually fade, and disappear after a few days, and the skin eruption also declines, the cuticle peeling off in large quantities, because of which the coat becomes very scurfy. The second form (scarlatina anginosa) appears as an aggravated condition of the simple form. In it the limbs swell rapidly and pit under pressure. Circumscribed tumefactions occur, which are hot and tender; these may unite, forming larger swellings; others decline; while still others remain distinct, and at a later period become moist on the surface by reason of the discharge of a thin, yellowish fluid. Small swellings or pimples occupy the rest of the surface of the skin, similar to those of simple scarlet fever. The spots on the mucous membrane of the nose enlarge, and frequently run together, forming larger blotches, or the Schneiderian membrane may have a deep scarlet hue, sometimes merging into purple. The throat is involved greatly, noisy cough, with abundant discharge of mucus having various shades of red and yellow. Respiration is interfered with, the inspiration partaking of a roaring kind of sound, with snuffling through the nostril. Swelling takes place beneath the jaws, sometimes also under the shoulder and in other places. Symptomatic fever usually runs high in proportion to the amount of eruption and soreness of throat. Pulse weak, small, and compressible (60 to 100) in intense cases. Respiration rapid. Bowels constipated, although diarrhœa is rapidly induced. Urine deficient, thick, and offensive. In the most favorable cases the throat affection disappears side by side with the eruption on or about the fifth day.

FUNCTIONAL DISEASES OF THE HEART.

By E. P. HURD, M.D.,

NEWBURYPORT, MASS.

PART I.—PHYSIOLOGICAL.

CLAUDE BERNARD in some of his physiological works felicitously shows the fundamental similarity and unity of all living elements, whether pertaining to the highest or the lowest organisms. The primary conditions of living are the same in all: warmth, moisture, pabulum, oxygen. These must be supplied by their environment; aquatic animalcules obtain them in the liquid medium in which they live, and the essentially living elements of the higher animals dwell in and are constantly bathed by an "interior medium," the circulating blood, which is their real environment. The life of these anatomical units is in strict and absolute dependence on a constant renewal of this fluid, and the heart, of all the organs of the body, is the one whose function begins the earliest and lasts the longest. It begins its untiring work long before it is developed; its perseverance in toil is in the ratio of the importance of the mission which it fulfils; it is the *primum movens*, and the *ultimum moriens*.

"Whatever the complexities of the human organism," says Frederick Harrison, "there is throughout the whole the solidarity of a single unit."

The presence of a nervous system is no more an indispensable factor of this organic unity than is the presence of a circulatory system, and integrity of the central organ of circulation is necessary for the healthful performance of all function.

The demonstration of this proposition is the well-known effects of disease of this organ. Take as an example a well-marked case of aortic insufficiency (Corrigan's disease). Here, with every diastole of the heart, a portion of blood, thrown into the aorta during systole returns, and you have constantly the pulse of unfilled arteries; there is oligæmia in the capillary system. As a consequence the vital elements are everywhere ill nourished. The brain is anæmic and irritable, thought is sluggish, psychical action generally is perverted and deranged, innervation languishes. The powers of the digestive system are impaired; the alimentary canal is the seat of venous stasis in which the other abdominal viscera participate; frequent attacks of dyspnœa (dyspnœa which becomes more and more permanent) testify to the profound disturbance of the pulmonary function.

The reciprocal influence of the organic processes on the heart has been for ages a matter of observation, though it is only of late years that its mechanism has been known; if integrity of the heart be essential to the healthful performance of the systemic functions generally, integrity of the latter is equally essential to the normal working of the heart.

The slightest emotion causes some brief disturbance of that organ; a powerful emotion may temporarily or permanently suspend its action; the stimulus of volition may goad on the heart to efforts which end in exhaustion or in disease. Peripheral irritations—manifested to consciousness as pain—may raise the blood-pressure in the viscera, and visceral irritations may augment the heart's action, or inhibit it altogether.

Nothing can, in fact, be more interesting than this whole study of the reciprocal action of the organism on the heart. Hard thinking calls, as it were, more blood to the brain, and the heart does not fail to respond to the demand; severe muscular exertion drafts more blood to the muscles; the process of digestion requires more blood than is required during a quiescent state of the stomach; during gestation the heart of the pregnant woman is taxed to an extraordinary degree, etc.

If every powerful sensation may, as stated above, exalt or depress the heart's action, and if obscure visceral sensations may have the same effect, then it is obvious that the heart may be deranged, temporarily or permanently, by its environment, if the disturbing causes be too violent or too persistent. That the heart is something besides a mere force-pump or hydraulic machine; that it has a wonderful power of adapting itself to changes in its internal and external circumstances; that it is in the closest relations with the tissues which it nourishes—sharing in their well-being, suffering with their derangements—is explicable, as a physiological fact, by a consideration of the nervous mechanism of the circulatory organs.

The cardiac innervation comprehends certain intra-cardiac ganglia, extra cardiac ganglia, and nerves, derived from the sympathetic and cerebro-spinal system.

I. *Intra-cardiac ganglia.*—There are in the walls of the heart certain ganglia whose office is to promote and regulate the rhythmical working of the cardiac muscle. Not that the ability rhythmically to contract is not an inherent property of the myocardium to a certain extent, independent of the nervous system. It is nevertheless true, that in the performance of its ordinary function the heart is governed by nervous influence. Certain of these ganglia (ganglia of Remak) are placed at the point of entry of the nerves of the heart, the cardiac branches of the sympathetic and pneumogastric, whose terminal filaments are lost in these ganglia; they occupy the sinus of the vena cava. Other ganglia, those of Bidder and Ludwig, are situated in the auriculo-ventricular furrow. In these ganglia originate fibres, some of which, centrifugal, are distributed

to the muscular fasciculi; others, centripetal, terminate in the endocardium. These ganglia, with their centripetal and centrifugal nerves, constitute an excito-motor arc, and are to a certain extent independent nerve-centres.

II. *Extra-cardiac ganglia.*—If we are to understand by this term every nerve-centre which influences the heart, we should have to include the entire cerebro-spinal and sympathetic system; the cardiac centre, *par excellence*, however, is the medulla oblongata. When by means of powerful electric currents you excite the rachidian bulb between the tubercula quadrigemina and the calamus, you obtain an arrest of the heart, or a simple slowing of the movements of this organ, according to the intensity of the current employed.¹ If previously you cut the pneumogastric nerves, the excitation of the bulb at the point indicated produces an acceleration of the movements of the heart. It would seem, then, that the medulla oblongata may, according to circumstances, cause retardation or acceleration of the cardiac contractions; it is especially the centre of impressions, which reflexly affect the frequency and rhythm of the cardiac movements.²

It is inferred that the effect of increased blood-pressure in slowing the pulse when the vagi are intact is brought about through this augmented pressure stimulating the cardio-inhibitory centre in the medulla, and thus partially inhibiting the heart (M. Foster, "Physiology," p. 151). The inhibitory action of the pneumogastric on the intra-cardiac ganglia is not well understood. That this inhibition coexists with augmented innervation and augmented energy is indisputable. Through the influence of the pneumogastric a more complete and extensive *libero-motor* action is obtained in the intra-cardiac ganglia, which, thus energized, slowly but thoroughly evoke the consentaneous activity of all the constituent fasciculi of the myocardium. It is "a long pull, a strong pull, and a pull altogether."

Other extra-cardiac ganglia exist in the cervical portion of the spinal cord. These ganglia may be regarded as the centres of the accelerator nerves—the thoracic-spinal filaments, as well as those which emanate from the great sympathetic (the latter having its origin in the spinal cord). Von Bezold has proved that excitation of the spinal cord, especially in its upper portion, augments the energy of the heart and the arterial pressure. It is worthy of note that these centres (auxiliary cardiac ganglia) are in the closest relation with the vaso-motor centre, and that any excitation which raises arterial tension may be attended with accelerated cardiac action. Ludwig and Thiry have clearly proved this intimate relation.

III. *Accelerator and moderator nerves of the heart.*—There are certain nerves whose office is to quicken, others whose office is to moderate the action of the heart.

1. *The accelerator nerves* are intimately blended with the sympathetic system passing through and being associated with the lower cervical and the upper thoracic ganglia, but they are ultimately derivable from the cervical spinal cord. Irritation of the sympathetic or cervical spinal cord produces acceleration of the heart's pulsations through these nerves.³ Very strong faradic currents are needed for effecting this result; these nerves seem to be unaffected by the various poisons which act upon the vagus and other parts of the nervous system; they are effective in the midst of profound asphyxia.⁴ They are not considered as antagonistic to the pneumogastric, for if during maximum stimulation of the accelerator nerves the vagus be stimulated, even with minimum currents, inhibition is produced with the same readiness as if these were not acting. But little is known of the actual share which these nerves take in the natural actions of the economy.⁵

² Germain Sée: *Loc. cit.*, p. 421.

³ Foster's *Physiology*, p. 148. Germain Sée: *Maladies du Cœur*, p. 417.

⁴ M. Foster: *Loc. cit.*

⁵ Baxter: cited by Foster.

Indirectly, by reflex action, acceleration of the heart's movements is produced by excitation of the great splanchnic nerves, which causes contraction of the intra-abdominal vessels, increase of blood-pressure, and acceleration with augmentation of energy of the heart's action.

2. *The moderator nerves.*—It was a surprise to the world when Weber announced, forty years ago, the discovery that galvanization of the pneumogastric would arrest the heart's action. It was a greater surprise when the experiments of Weber, repeated by Budge, Waller, Brown-Séquard, and others, demonstrated that the heart, instead of being arrested in a state of spasm or contraction, was in a state of complete relaxation under the inhibition of a stimulus conveyed along the par vagum. A moderate excitation of the pneumogastric slows the heart's action, a violent excitation arrests it in diastole; but this excitation, if continued, is followed by acceleration of the cardiac movements from exhaustion of the pneumogastric. According to the experiments of Waller, the direct inhibitory fibres of the pneumogastric are derived from the spinal accessory.

If the pneumogastric is, *par excellence*, the moderator nerve of the heart, among its filaments is a sensory nerve, which is distributed to the heart, and which when irritated produces by reflex action dilatation of the splanchnic intra-abdominal vessels and lowering of the arterial pressure with slowing of the heart. This nerve is an inhibitory nerve, acting indirectly; it has a common origin with the pneumogastric in the medulla oblongata. Discovered by Ludwig and Cyon, it is called the depressor nerve of Cyon. Any excitation of the terminal endocardial filaments of this nerve is reflected from the medulla oblongata on the splanchnic nerves through the intermediation of the spinal cord, extreme dilatation of the abdominal vessels takes place under the influence of this excitation, and a large sluice-way is opened for a great mass of blood; there is thus a considerable depletion of the blood-vessels of other portions of the body, the peripheral resistance is reduced to a minimum, the heart's work is lessened, and the blood-pressure is lowered.¹

As auxiliary to the cardiac nervous mechanism above mentioned, we have the vaso-motor nerves of the entire economy. Acceleration or retardation of the movements of the heart may be obtained by influences affecting the vaso-motor nerves. If we may consider these nerves as consisting of vaso-constrictors and vaso-dilators, any irritation of a sensory nerve will cause vaso-constriction of a part, and this augments peripheral resistance, and the work of the heart, whose pulsations are characterized by greater frequency and energy. The influence of an impression on the vaso-motors sufficient to markedly raise the blood-pressure and quicken the heart is seen when the great splanchnic nerve is moderately excited by electricity, as this nerve contains the vaso-constrictors of the intra-abdominal vessels—an experiment which has been described by Vulpian, Foster, and all recent physiologists. On the contrary, section of the great splanchnic is attended with abdominal vaso-dilatation and a marked fall in general blood-pressure, with lessening in the force and frequency of the pulse.

Influence of the blood-vessels on the heart.—Any considerable modification in the peripheral circulation, due to vaso-constrictive action, is attended with acceleration and augmentation of the heart's action. Claude Bernard attempts an explanation of this fact in a remarkable lecture on the physiology of the heart and its relations with the brain, delivered in 1865, but, singularly, invokes only the well-known influence of the pneumogastric. Vulpian has studied the subject more profoundly.² "Suppose," he says, "that under the influence of severe pain, caused by a wound, or even by pinching the skin in some place, there is produced a

contraction of the greater part of the arterioles of the body, there will be augmentation of arterial tension, and the heart will have to struggle against this excess of tension. This organ will then be forced to put forth more energy to propel each ventricular wave into the aorta and arterial system. Not only will the cardiac contractions be more vigorous, they will become more rapid. Now it is clear that this reaction of the heart is not purely a mechanical effect. The modifications which characterize its movements are due to the putting in play of the apparatus of innervation of the heart. Under the influence of augmentation of the intra-arterial pressure, the blood contained in the ventricle undergoes, at the moment of systole and the opening of the sigmoid valves, an excess of tension. Hence results, without any doubt, a particular impression in the endocardial extremities of the centripetal nerves of the heart. This impression is carried to the rachidian bulb by the pneumogastric. There a phenomenon of central innervation takes place, as a result of which a centrifugal excitation, emanating from the medulla oblongata and the cervical region of the spinal cord, is conducted to the intra-cardiac ganglia by the cervical sympathetic cord and its ganglia. The fibres emanating from the cervical sympathetic cord and the superior cervical ganglia are probably those whose operation provokes a redoubling of energy of the movements of the heart. As for the acceleration of movements, this depends on excitation of the accelerator nerves which spring on each side from the third branch of the inferior cervical ganglia.

We see from this that the simple fact of contraction of the vessels has for necessary consequence, when the heart and its nervous apparatus are in the normal state, a very remarkable reflex modification of its movements.

If the peripheral vessels, arterioles and veinules dilate instead of contracting, phenomena just the reverse take place, the heart will contract more feebly and more slowly. The impression produced on the endocardium by the diminution of intra-arterial tension, will be necessarily very different from that which took place under the conditions which we have just examined.

Different phenomena of central innervation also are awakened in the rachidian bulb. This time the centrifugal excitation will put in activity the cardiac fibres of the pneumogastric. Under the influence of excitation of these fibres the movements of the heart will become weaker and slower.

The important point now to be noted is this: If the heart may be modified in its action by the condition of the arterioles and capillaries of a more or less circumscribed portion of the body, it may be deranged thereby temporarily, and even permanently. Functional derangements coexist with integrity of the heart-substance and the valves; but a persistence or intensification of the causes which give rise to functional troubles may produce organic disease. There is a morbid condition of the arterioles and capillaries known as arterio-capillary fibrosis, described by Gull and Sutton, Broadbent, Burdon-Sanderson, Mahomed, Lecorché, and others. According to Gull and Sutton's hypothesis, this pathological condition, when it affects the renal circulation, is the chief secondary etiological factor of chronic Bright's disease—the morbid alteration of the blood—which causes these vascular degenerative changes, being primary. The high arterial pressure which results from this sclerosed condition of the arteries eventually entails on the heart dilatation and hypertrophy; but long before this structural modification takes place, the heart, laboring to surmount the peripheral resistance, manifests by exaggerated action its increased burden. The irritation of the centripetal nerves of the endocardium by morbid blood is undoubtedly, in these cases of chronic interstitial nephritis an important factor in the production of the ensuing cardiac changes. It is none the less true, however, that the mechanical obstructions are enough of themselves seriously to tax and embarrass the heart, which if it fail

¹ Vulpian: *Appareil Vaso-Moteur*, t. i., p. 354.

² *Ibid.*, t. i., p. 366.

to meet the extra demands made upon it, will make known its incompetence by derangements of rhythm, passive dilatation, and asystolism.

Relation of work to the heart's action.—Severe exercise—physical and mental—increases the frequency and energy of the heart's pulsations. Augmentation of function necessitates a more abundant sanguineous irrigation. The working muscles or working brain demand more blood, and the heart is stimulated to increased activity. The mechanism is not easy of explanation. There are probably simultaneously going on vascular contraction and vascular dilatation, augmentation and diminution of pressure. Vaso-dilator action undoubtedly predominates in the parts under exercise, and though peripheral resistance is lowered, vascular tension is raised. This is practically the case, although theoretically it would seem as though it must be otherwise.¹ The pulse beats rapidly and with energy. A relatively quick pulse is quite compatible with a hard, strong pulse, and in experiments on animals it is generally noted that the movements of the heart are accelerated with augmentation of the intra-arterial pressure. It is also true that in the human subject a slow pulse and a strong, high-pressure pulse very often go together. The heart may meet its increased tasks by slow powerful beats, or by greater celerity of action, putting forth as much force in the one case as in the other.

The practical point to be now presented is this: If exercise compels the heart to do more work, severe exercise may enfeeble, and even exhaust the heart. This is the important physiological lesson for us now. There is no hard and fast line between that exaggerated action which accompanies overwork, and that exaggerated action known as palpitations.

The heart undoubtedly possesses extraordinary endurance and is popularly said never to rest. It may, however, be overtaxed and enfeebled, like any other muscle. This enfeeblement may manifest itself as want of muscular tone, which may result in dilatation, or in hyper-irritability of the intrinsic nervous ganglia of the heart, or its sensory nerves, the latter pathological condition finds expression in ataxia, arrhythmia, or intermittence, all resulting from exhausted cardiac innervation.

Modification of the heart's action by toxic agents.—We can experimentally produce accelerated action of the heart in animals by injecting certain poisons, as nicotine. After a moderate subcutaneous injection of nicotine there results a considerable acceleration of the pulse from paralysis of the inhibitory system.² We have actually produced palpitations, such as we see so often in smokers, from the depressing effect on the functions of the par vagum of tobacco. The toxic effect of nicotine is exerted on the bulb, whose reflex excitability it lessens and abolishes.

Similar effects on the heart and pulse may be produced by belladonna, or its alkaloid atropia, which is a veritable paralyzer of the pneumogastric.

Influence of emotion on the heart.—Enfeeblement and even paralysis of the inhibitory cardiac centres is witnessed under the influence of strong emotions. Everybody is familiar with the effect of fear in accelerating the heart's action. Intense sorrow or disappointment suspends the functional activity of the higher nerve-centres, and the heart in consequence lacks certain important stimuli to action. This organ, then, is hindered and inhibited in its action by the painful emotions; while the cheerful emotions raise the blood-pressure and energize the heart and circulation. These are facts of common experience.

It is scarcely possible at the present day to give a satisfactory explanation of the effects of the emotions on the heart and circulation. Fear and rage, for instance, cause powerful perturbation of the vaso-motor system, and make the heart beat quickly, wildly, and violently; and yet, as Darwin says,³ it does not pump the blood

more efficiently over the body, for the surface seems bloodless, and the muscular strength soon fails. At other times, the first depression is followed by vigorous reaction, in which the heart rebounds, as it were, like the horse which has felt the spur. The heart is, as Claude Bernard says, the most sensitive of the organs of the vegetative life, and undergoes some modification in response to every emotion.

The lesson which I wish now to convey is this: If the heart may be modified in its operations by strong emotion, it may be deranged thereby. Persistence of the cause will produce persistence of the effect, and functional perturbations engendered by grief, suspense, disappointment, etc., may, if the depressing emotion be long continued, become chronic. Here we have a possible explanation of many of those cases of chronic, so-called "essential" palpitations, when, for a series of years, there is inordinate frequency of the heart's pulsations without organic disease. Every disturbance of rhythm necessitates a new adjustment in correspondence with changed conditions, and equilibrium of any kind once established, tends toward permanence. The persistence of organic habits is, as Mr. Herbert Spencer would say, a corollary from the persistence of force.

Physiology thus furnishes important hints as to the possibility, the causes, and the modes of functional heart-troubles. The next paper will be occupied with Pathology.

LICHEN RUBER OF HEBRA AND LICHEN PLANUS OF WILSON.

By A. R. ROBINSON, M.B., L.R.C.P. & S.,

PROFESSOR OF DERMATOLOGY IN THE NEW YORK POLYCLINIC; PROFESSOR OF HISTOLOGY IN THE WOMAN'S MEDICAL COLLEGE OF THE NEW YORK INFIRMARY; ATTENDING PHYSICIAN TO DEMILT DISPENSARY, SKIN DEPARTMENT, ETC.

In this paper I will describe the symptoms, anatomy, prognosis, and treatment of lichen ruber of Hebra, and of lichen planus of Wilson, with the object of comparing, in these several respects, the two forms of eruption described under these terms, and of estimating the tenableness of the grounds for regarding them as inflammatory or exudative affections, and but different forms of the same disease.

All writers except Auspitz consider the papules in both cases to be inflammatory in origin, and all except Neumann regard them as but constituting different forms of the same disease.

I will describe lichen ruber first and lichen planus afterward.

Lichen ruber of Hebra.—The symptoms here given are principally those described by the Vienna dermatologists, as their opportunities for studying the disease have been so much greater than those of physicians of other countries. In America I have had the opportunity of observing only one case, that of a man under the care of Dr. McMaster, of New York City. From this person I removed several papules, and the drawings Nos. 1 and 2 were made from sections of some of these papules.

Symptoms.—At the commencement of the disease the eruption consists of isolated, slightly scaly, millet-sized papules which appear in two forms; in the one form they are disseminated, of a bright or brown-red color, very dense in consistence, conical in shape, and the apex covered with a firmly adherent, dry, white, scaly mass which gives a rough feel to the touch. In the other form they are also disseminated and of similar size as those of the preceding form, but are pale-red in color, of a waxy shining appearance, the surface is smooth, rounded, and has a small central depression. This central depression corresponds to the orifice of a hair-follicle. The eruption may appear upon any part of the body, but generally commences on the thorax or abdomen and afterward extends to the extremities, genital regions, and other parts of the body. The papules preserve their original dimensions during their entire

¹ See Vulpian's Explanation, loc. cit., t. i., p. 476.

² Germain Séé: Op. cit., p. 232.

³ Expression of the Emotions, etc., p. 76.

existence, never increasing in size by growth at the periphery, the extension of the eruption always depending upon the formation of new papules of similar size and appearance to the already existing ones. These new papules which are being continuously formed arise either in an irregular manner upon the skin or in a row-like arrangement around or between existing papules. From this constant formation of new papules the skin over a greater or less area becomes more and more occupied by the eruption, until finally the whole area is covered by them, and consequently neighboring papules come in contact. When this last condition is present the eruption appears as a connected, red, infiltrated patch, covered with scales, and having a dry, rough, uneven surface. At the periphery of such an area or patch, characteristic individual papules are always to be observed.

Instead of this irregular and diffuse manner of formation of subsequent papules, they sometimes arise in the form of several circles of closely seated papules around an already existing papule. Afterward the more centrally seated papules sink in, become absorbed, and finally disappear, generally leaving the skin pigmented and atrophied in spots. In this manner variously sized patches arise, the central part of which is pigmented and contains atrophic depressions, while the periphery is formed of one or more rows of wax-like shining, umbilicated papules. I take it for granted that the umbilication of these papules as here met with depends upon the retrograde process taking place in them, and is not a primary condition. The papules never undergo any changes except resolution from cessation of the formative process, or atrophy from degeneration of the elements forming the papule.

The irregular and diffuse form of extension of the eruption is much more frequent than the aggregated and circular, and is generally the only form present, but the other may also occur exclusively, or, as occasionally happens, both forms are observed on the same person; in which case the former is met with principally on the trunk, and the latter on the extremities.

No matter in which form the eruption spreads, or whether it is accompanied by atrophy and pigmentation or not, it finally, as a rule, extends so as to occupy the whole cutaneous surface, when all signs of papule formation disappear, and the skin appears everywhere reddened, thickened, furrowed, and covered with numerous thin, whitish scales. The skin of the face becomes dry, cracked, and scaly, the lower lids ectropic, the upper lids droop. The thickness of the skin is especially to be observed on the palms of the hands and on the soles of the feet, where the eruption does not appear as papules, but as great thickening of the corneous layer. The fingers and toes in consequence of this thickening stand out apart from each other, half bent, and show, besides redness and infiltration, deep fissures and rhagades. Muscular movement is interfered with, especially at the joints so that the patient can only with difficulty keep the extremities fully extended or flexed, and consequently seeks a position between these two conditions.

When the eruption is general over the whole surface the nails always become affected; they are greatly thickened from a deposit of nail-substance from the bed of the nail, are of a yellowish-brown color, very brittle, and have an uneven surface. If the deposit takes place from the matrix alone, then the nail consists only of a short, thin, brittle plate, which projects from the flesh.

The nutrition of the hairs at the seat of the eruption is always interfered with, the hair becomes thinner, falls out, and is replaced by lanugo hairs. The hair of the head, axillæ, and pubis, situations where it grows stronger, and is most deeply seated in the skin, resists the process longer than that of the rest of the body.

The eruption appears without prodromal symptoms, and the papules, if situated on the covered parts of the body, may have developed without the knowledge of the

individual affected. During the first stage, and also subsequently, there may be considerable itching present, but it bears no relation to the intensity of the eruption, and is much less than that accompanying many other skin affections. The general nutrition of the body is not interfered with until the eruption occupies a considerable area, when it suffers, and if the entire cutaneous surface is occupied by the disease the system becomes more and more affected, and after a few years the person passes into a marasmic condition from which he dies, unless he previously succumbs to complications depending upon this marasmic condition, as pneumonia, pleurisy, intestinal diseases, etc. This is the natural history of the disease, but under proper treatment the eruption may disappear without affecting the general constitution, or leaving traces of its previous existence upon the skin. When removed by treatment the disease is not liable to return. If it is not very extensive it may also disappear spontaneously.

Histology.—According to Hebra¹ no matter how red the skin appears before death it is found on post-mortem not to be thickened, but only pale, flabby, devoid of fat-tissue, and covered with a greater or less amount of scales. Under the microscope the hair-follicles are funnel-shaped with the apex of the funnel downward, and the papillæ and papillary vessels enlarged.

Neumann ("Lehrb. d. Hautkrankheiten," p. 308, Wien, 1880) found the corneous and rete layers increased in size, the interpapillary portions of the rete enlarged and showing growth downward into the corium. The papillæ were partly sunken and atrophied, and partly, especially at the periphery of the papule, enlarged, and contained broad-meshed elastic fibres. The blood-vessels were enlarged, and cell-infiltration, especially around the vessels, was observed. The sweat-glands, ducts, and orifices were dilated by epidermic cells. The cells of the external root-sheath of the hair were increased, and formed conical projections into the surrounding tissue like in acinous glands. The root of the hair had a brush-like form. The muscles of the skin were hypertrophied.

Biesiadecki ("Untersuchungen aus dem Path. Anat. Institute in Krakau," Wien, 1872) does not consider that the changes described by Neumann, as occurring in the sheath of the hair-follicles, are characteristic of the disease or a necessary part of the process, as he found normal follicles within the area of the papules. He found the papillæ at the periphery of the papule swollen, the corium oedematous, the rete enlarged, and the central part of the papule corresponding to an area of about eight papillæ, sunken in and atrophied, thus producing the central depression or umbilicated appearance already described. He thought the atrophied centre corresponded to the place of insertion of a muscle-bundle, a view not compatible with the follicular origin of the papules. He also found colloid degeneration of the walls of the papillary blood-vessels.

Kaposi ("Path. u. Therapie der Hautkrankheiten," Wien, 1880, p. 403) agrees with the previous observers, but does not regard any of the changes described as characteristic or sufficient to explain the gravity of the affection.

From the foregoing we find that Neumann, Biesiadecki, and Kaposi do not agree as to the significance of the abnormal changes observed by them. All agree that the papillary blood-vessels are dilated and that there is an increase in the thickness of the corneous layer. That the hypertrophy of the external sheath of the hair-follicle is not characteristic as shown by its absence in some cases within the area of a papule. They attribute the umbilication of the papules to an atrophic process affecting the rete and papillæ of the central part of the papule, that is, the depression is a secondary condition depending upon retrograde changes occurring in an acuminated papule. The dilated papillary blood-vessels, the enlarged papillæ, the perivascular cell infiltration are probably

¹ Lehrb. der Hautkrankheiten, I. rster Band, Zweite Lieferung, p. 391. 1874.

the grounds for each of them classifying the eruption as an inflammatory exudative affection.

Before entering into a discussion as to the inflammatory nature of the disease, or as to what processes or conditions should exist in order to justify us in classifying a cutaneous disease as inflammatory in nature, I will describe the changes observed in the skin in the papules removed from Dr. McMaster's patient. I will first describe the changes which occurred in a recent papule, and afterward in one of much longer duration.

Fig. 1 represents a section of a recent papule as seen with a low magnifying power.

The section includes normal skin at both ends and a transverse section of an entire papule. With a low magnifying power, as the section is here represented, the corneous layer is seen to be greatly increased in thickness in the situation corresponding to the seat of the papule, the thickness being greatest in the central portion and becoming gradually less as the periphery is approached. It is very undulating in appearance, the most depressed parts corresponding to the orifices of sweat-ducts or hair-follicles. The rete mucosum is slightly increased in thickness by growth upward toward the free surface, as shown by the uneven upper part of the papule portion, as compared with the normal rete at the ends. There is also a growth downward into the corium of the interpapillary parts of the rete. This growth in thickness of the rete mucosum is neither of marked extent nor general throughout the whole area of a papule, as in some places the rete is of normal thickness. The corium appears to be normal. The papillary blood-vessels are slightly dilated, and a few lymphoid corpuscles may be seen in their neighborhood. Some hair-follicles are hypertrophied and others normal, except at their orifice, which is wide and filled with corneous cells. The unstripped muscle-bundles are seen to be hypertrophied.

FIG. 1.—Vertical Section of a Recent Papule of Lichen Ruber. *a*, corneous layer; *b*, rete mucosum; *c*, corium; *d*, unstripped muscle-bundles cut transversely; *e*, sweat-ducts; *f*, hair-follicle. The section includes normal skin at the periphery.

Examined with a high power, the corneous layer is found to be greatly hypertrophied, from an increase in the number and size of the corneous elements. The individual elements also show an aberration from the normal process of corneous transformation, as many of the cells of the lower layers are incompletely transformed, as shown by the presence of nuclei, and their coloring with carmine. The nuclei present are either granular in appearance or like vesicles (*aufgeblacht*)—that is, large, round, transparent bodies. These incompletely changed cells are met with especially about the orifices of the sweat-ducts and hair-follicles. All the corneous cells are much larger than normal and more polygonal in shape, especially in the lower strata. The rete mucosum appears slightly hypertrophied throughout the greater part of its extent, but in some places is of normal thickness.

There is a slight growth downward of the interpapillary portion of the rete, and a more marked growth upward from the super-papillary part, giving to the upper part of this layer an uneven surface. The rete cells are of normal size and appearance, and seem to be merely increased in number. The granular and stratum lucidum layers are not as distinct as usual, but this may depend upon the locality from which the section was taken, as they were not prominent in the healthy tissue. The papillæ are increased in size from the growth of the rete

downward; their blood-vessels are somewhat dilated, and a few emigrated corpuscles are present immediately outside the vessels. There is no appreciable œdema of the connective-tissue from inflammatory exudation. The corium is normal, except some of the blood-vessels are slightly dilated and a few emigrated corpuscles are present. The sweat-glands are normal, except the duct in the corneous layer, the walls of which are formed by large cells, some of which have vesicular nuclei. The hair-follicles are unaffected, except at the orifice, where there is a large collection of corneous cells. The muscle-bundles are hypertrophied to a marked extent.

Summing up the changes observed in the recent papule, we find the principal one to be in the corneous layer. Here there is a great increase in thickness from increase in the number and size of the component elements—not a true hyperplasia, but an increase from a para-typical process, producing a thickening of this layer. This thickness is also especially present at the orifices of the sweat-ducts and hair-follicles. The changes in the rete and in the corium are slight in amount, and there is an entire absence of any actual exudation, emigration, or change to an embryonic condition of the fixed elements of the corium, conditions indicating an inflammatory process.

In papules which have existed for a considerable length of time there is a continuation of the processes observed in the recent papule and afterward retrograde changes leading to atrophy of the part, or there is a return to the normal condition by cessation of the pathological process.

FIG. 2.—Vertical Section of a Papule of Lichen Ruber which had existed Several Weeks. (More highly magnified than Fig. 1.) *a*, corneous layer; *b*, rete mucosum; *c*, region of sweat-duct orifice; *d*, corium; *e*, unstripped muscle-bundle (from the lumbar region).

The corneous layer is much thicker than* in recent papules, but the character of its elements as regards shape, size, structure, and chemical constitution remain the same. Coloring with carmine shows a number of them, especially in the region of the orifices of the sweat-ducts and hair-follicles, still contain a granular nucleus while others have a vesicular one. The free surface is not provided with the dry, flat, squamous cells observed in normal epidermis from this region. The rete mucosum is somewhat increased in size and from its upper portion it sends projections toward the free surface. This unevenness of its upper surface as seen in Fig. 2 depends but very slightly upon the rete, for we observe that where these projections exist the rete is not specially increased in thickness, as the cutis papillæ beneath these extend farther upward than elsewhere. As the papillæ are not increased in size, at least to any marked extent, and the rete above them is not thicker there than in other situations, it follows that the uneven upper portion of the rete is produced by the hypertrophied corneous layer. This hypertrophy of the corneous layer is greatest in the region of the orifices of the sweat-ducts and hair-follicles, and there the projections extend farthest downward. The rete

cells are not increased in size, but in many places are very small, a result probably of pressure upon them by the corneous layer. The granular layer and stratum lucidum are not well defined. The interpapillary portions of the rete are increased in size in some situations by slight growth downward into the corium. The cutis papillæ are but slightly enlarged, the enlargement depending upon the changes in the interpapillary rete: the papillary blood-vessels are somewhat dilated, and a few emigrated corpuscles are present outside the vessels. Some of the papillæ are diminished in length from the downward pressure of the rete and corneous layers.

The structure of the corium is normal except in the neighborhood of the blood-vessels. The majority of the blood-vessels are dilated and surrounded by a variable number of lymphoid corpuscles—emigrated corpuscles. The dilatation of the blood-vessels and the number of emigrated corpuscles is greater than in recent papules, but not sufficient to denote any active process. The unstriped muscle-bundles are always much hypertrophied, much more than in any other cutaneous disease. Some hair-follicles show hypertrophy of the external hair-sheath while others are normal.

In the central portion of old papules a retrograde process often occurs, consisting in a degeneration of the rete and destruction of a portion of the underlying corium. In some of my sections I found a separation of all the rete except the lowest layer of cells from the cutis. I am unable to describe the changes which led to atrophy of the part, as I did not remove any papules with atrophic centres.

Deductions.—In the examination of sections of papules of lichen ruber of recent or long existence, it will be observed that we find no liquid exudation; no emigration of white blood-corpuscles, except a few from the blood-vessels of the papillæ and upper part of the corium, the number of which increases with the duration of the disease; no change in the fixed elements of the part to embryonic conditions, that is, none of the characteristic microscopic appearances observed in a vascular tissue, which is the seat of an inflammatory process. The few changes observed in the papillæ are due to distention of the blood-vessels and consequent stasis, while the slight increase in size of some of them results from a growth downward of the interpapillary rete, a growth which is perhaps never the result of an inflammatory process. Some (Auspitz) maintain that there never is a hypertrophy of the rete, the result of an inflammation of the skin, but, I believe, that though it is an unusual occurrence, yet it nevertheless occasionally occurs in cases of chronic eczema. Dilated blood-vessels and the presence of emigrated corpuscles may also denote an inflammatory process in the skin, but unless this process is primary, and not secondary to other pathological conditions, the disease in which it occurs is not to be classed among the inflammatory or exudative affections. In many skin diseases that we know are not inflammatory in nature dilatation of the blood-vessels and emigration of white blood-corpuscles occur, but only as a secondary condition, as for instance, in ichthyosis and verruca. The changes in these two diseases, as regards dilatation of the blood-vessels and emigration of corpuscles, are secondary to other changes in the epidermis, and hence are not inflammatory diseases. If lichen ruber was an inflammatory disease, the changes in the corneous layer would require to be a secondary condition, and the result of nutrition changes consequent on the inflammatory process. We find, however, from microscopical examination, that the primary and principal changes occur in the corneous layer, that the other changes observed are slight in comparison with them, and, furthermore, that such changes as occur in the corneous layer, are, I believe, never the result of an inflammation.

From a clinical study of the papule there is also nothing in its mode of origin or appearance which makes it probable that the disease is an inflammatory one. The

redness present is principally a hyperæmic redness, as shown by the absence of an inflammatory areola; there is no pus formation, no abscess, no vesicles, no erosion, no exudation upon the free surface, no inflammatory infiltration into the cutis, no pain; no increase of temperature, judging by the feel—in other words, the essential clinical characters of an inflammation are absent. It is true that a disease may be inflammatory in origin and consist of nothing but papules, as occurs in ordinary lichen or papular eczema, but in this case several of the above-mentioned clinical characters of an inflammation are present, and microscopical examination shows not only dilatation of the blood-vessels, but also exudation, emigration, and change in the tissue of the part. In the majority of cases of this papular eczema, also, papules are intermingled with vesicles or papulo-vesicles, whereas in lichen ruber the papules never become vesicles and never change in character, except to undergo revolution or atrophy.

From a consideration of these clinical and anatomical characteristics of lichen ruber it seems unjustifiable to classify it among the inflammatory or exudative affections of the skin, provided my observations on the anatomy of the papule in its different periods of existence, and views as to the conditions to be necessarily present to constitute an inflammatory process, be correct. The arguments advanced in reference to the clinical characters necessary to constitute an inflammation are similar to those held by Dr. Auspitz, and may be considered tenable.

The anatomy of the papule, as far as the condition of the corium and blood-vessels is concerned, does not differ much from that given by Neumann, although he regards the slight emigration as proof of an inflammatory process. A reference to his drawings will show how insignificant this emigration is compared even with that of the skin in scarlatina. I find that the principal pathological changes are present in the corneous layer, and that the changes in the other tissues are secondary and slight in amount. There is great increase in thickness in the corneous layer—a hypertrophy and an aberration in the process of horny transformation, as already described. Now the horny transformation is a complicated physiological and chemical process, and an excess or aberration of the process may occur without simultaneous changes in the rete. An excessive production of corneous cells may, by pressure upon the rete corpuscles, produce a super-nutrition of these corpuscles and consequent thickening of the layer as occurs in callosities. This continuous pressure upon the rete and underlying cutis, a pressure which increases in amount until the papule has reached its acme of development, is a sufficient explanation for the atrophy which occurs in the centre of old papules without the addition of an amyloid degeneration of the papillary blood-vessels as advanced by Biesiadecki, a condition which was, moreover, not present in my sections. The hypertrophy of the external root-sheath of the hair was absent in some of my sections as well as in those of Biesiadecki, and consequently cannot have the importance attached to it by Neumann. The hypertrophy of the unstriped muscle bundles, on the contrary, is evidently a constant condition and an essential part of the process of the disease.

In lichen ruber, then, we find that the principal pathological changes occur in the corneous layer, and that these changes consist in an increase in thickness from an excessive production of corneous cells and an aberration in the process of horny transformation. These changes occur especially in the region of the orifices of the sweat-ducts and hair-follicles. There is a digression from the normal physiological process of horny transformation—a keratosis, and a para-typical keratosis, a para-typical anomaly of horny transformation. It is shown to be a keratosis by the changes in the corneous layer being the primary and characteristic pathological condition, and to be a para-typical keratosis by the di-

gression from the normal process of transformation, as of the cells, as regards size, shape, structure, chemical constitution, and manner of being cast off. Lichen ruber, then, is not an inflammatory disease, but arises from a continuous collection of epidermic cells from an anomaly in the process of their production and casting off, and these cells, by pressure upon the underlying tissues, produce the other changes occurring in the rete and corium.

Prognosis.—The disease, if allowed its natural course, or is not treated by means of arsenic, invariably proves fatal, as shown by the result in the first fourteen cases under Hebra's care. When treated by arsenic in the manner recommended by Hebra, the disease can always be removed, unless the person is already in a very advanced stage of marasmus.

Treatment.—With the exception of arsenic there is no known preparation, either applied externally or given internally, that has any effect upon the course of the disease. Arsenic alone is to be relied upon, and if given in sufficiently large doses and its use persisted in the eruption will disappear. It is to be given at first in small doses, and the quantity increased every four or five days until the maximum dose which can be well borne by each individual is reached, and this dose continued until the eruption has disappeared, when smaller quantities should be given for three or four months longer. To abate the itching, baths or the application of fat substances alone or combined with carbolic acid, salicylic acid, or zinc may be employed, but, as a rule, are of little benefit.

(To be continued.)

ON SOME NATURAL MODES OF CURE IN EMPYEMA.

BEING THE ABSTRACT OF A CLINICAL LECTURE.

BY WILLIAM OSLER, M.D., F.R.C.P., LOND.,

PROFESSOR OF THE INSTITUTES OF MEDICINE, M'GILL UNIVERSITY, MONTREAL.

GENTLEMEN: Most of you have seen what *Art* can do in the treatment of empyema, and I am thankful to say that, by the plan we now follow, of thorough drainage with a large canula and antiseptic dressings, we have had very fortunate results; but to-day I wish to call your attention to two cases which illustrate what *Nature* can do in the way of cure in this formidable affection. Left to itself an empyema may terminate as follows: 1, By perforation of chest-wall, of lung, and of diaphragm; 2, kill by septic or other influences; and 3, it may be absorbed or dry up. Of these three modes perforation is not very common either into the lung or externally, while into the abdomen it is very rare. Septicæmia claims no small proportion of fatal cases. Amyloid degeneration and tuberculosis kill not a few. Inspissation of the purulent contents and gradual absorption is perhaps the rarest of all terminations. A natural cure may take place by perforation of the lung or by the absorption of the pus, and of the three cases of empyema which you have had an opportunity of studying this session, two furnish illustrations of these modes.

Let us first study the case of the Swede who was discharged from Ward 11 a few days ago. The clinical report is as follows:

CASE I.—*Typhoid fever; empyema; expectoration of the pus; recovery.*—Christopher I—, aged twenty-three, a Swede, was admitted to hospital on March 26th with typhoid fever. The attack was moderately severe, but presented no special features. The chest was examined on admission, with negative results. Toward the end of April (28th) as the temperature kept up, and he had a cough with shortness of breath, the lungs were examined, and absolute dulness found at the right base, extending as high as the spine of the scapula behind, and the fourth rib in front. The breath-sounds were not audible, and both tactile and vocal fremitus were absent. A hypodermic needle was inserted, and about twenty

minims of creamy pus withdrawn. Patient had no chills, no sweating; there was usually an evening exacerbation of temperature, two or three degrees, only once reaching 103°. It was decided to wait for a week before operating, and meanwhile to improve his general condition as far as possible. On May 1st, without any aggravation of symptoms, he began spitting up pus, and in the course of twenty four hours filled the spittoon (capacity 26 ozs.). The cough was very troublesome, not paroxysmal, and the pus was brought up in rounded masses surrounded by clear mucus. *En masse* it looked like pure pus, but the isolated sputa resembled closely those of chronic phthisis. No elastic tissue was found; pus cells were the only elements. On May 3d the area of dulness was found to have diminished considerably, and at the angle of the scapula breath-sounds could be heard, distant on tranquil respiration, harsh and distinct on deep inspiration, and these accompanied by *very fine crepitant râles*.

For nearly three weeks the expectoration of pus continued, the amount at first large (15–22 ozs.), and by the 20th was reduced to a couple of ounces daily. The dulness gradually diminished, and by the 13th a comparatively clear note was obtained on the portion of the infra-scapular area next the spine. Breath-sounds weak but quite audible; moist sounds on deep inspiration. His general condition improved rapidly, temperature became normal, and he was discharged June 4th. A slight area of dulness remained in the outer part of the infra-scapular region. While under observation a loud, rough, systolic murmur developed, heard in the third and fourth interspaces to the right of the sternum; not at the apex or at the base. It was transmitted to the right base, and was first noticed during auscultation of this part.

I may safely say, gentlemen, that in no case which has been in the wards this session did we watch with greater interest the progress of the disease, and we can regard the result with equal satisfaction.

That an empyema may perforate the lung and be coughed up has been known for centuries; but a knowledge of the fact that this occurs without the development of pneumothorax, and constitute one of the most favorable modes of termination of the disease, does not appear to be very widely diffused. Hippocrates, indeed, knew of it, and in several places speaks of recovery from empyema (after pneumonia) by perforation of the lung and expectoration of the pus.

Traube¹ in an article, published in 1872, entitled "On a Natural Mode of Cure in Purulent Pleuritic Exudation," has called special attention to the fact, and mentions, as a curious circumstance, that he alone, of all the physicians who had written on empyema since Hippocrates, had observed it. In this, however, he was mistaken, for it had not escaped the notice of the Irish physicians in the palmy days of the Dublin school. Dr. Greene² narrated several cases of the kind, and the late Dr. R. L. Macdonnell, the first professor of clinical medicine in this school, and who was at the time clinical assistant to Dr. Graves, in his important paper "Contributions to the Diagnosis of Empyema,"³ clearly recognized this group of cases.

There appear to be two ways in which an empyema may discharge through the lung; first, by opening into a bronchus and the formation of a fistula; and, second, by a local necrosis of the pulmonary pleura, exposure of the parenchyma, and a soaking of the pus through the spongy lung-tissue into the bronchi. In the first way pneumothorax usually develops and aggravates the danger. When the pus perforates by a large and free opening the patient may be suffocated by the sudden gush of fluid which is passed into the tubes more rapidly than it can be expectorated. Several cases of this kind are on

¹ Gesammelte Beiträge, Bd. iii., s. 44, 1878.

² Dublin Medical Journal, vol. xvii., 1840.

³ Ibid., 1844.

record. The establishment of a bronchial fistula may be followed by temporary relief, but permanent recovery is rare. In the second way the pus is usually discharged without the formation of pneumothorax, and we must regard this as one of the most favorable modes of termination in empyema.¹ Traube was certainly the first to give a satisfactory explanation of the process, as he had an opportunity of studying the condition of the pleura and lung in one of these cases, and found on the lower lobe an oval area two and one-half by one inch with the pleura destroyed, and the lung tissue fully exposed, but no direct communication with the bronchi. That pneumothorax does not occur he explains in the view that while the powerful coughing efforts compress the chest, and are sufficient to drive the pus through the exposed lung tissue into the bronchi, the affected side is immobile, or nearly so, and the slight expansion during inspiration has not force enough to aspirate air into the pleura.

Greene, in the paper already referred to, clearly distinguishes between the two classes, stating that "in cases of effusion a copious and purulent expectoration is a frequent accompaniment, depending in some instances on a fistulous communication established between the seat of the collection and a bronchial tube, and that when such a communication has taken place it may be recognized by well-known and characteristic signs. But in other instances the expectoration may be equally copious and purulent, while all the physical signs of such communication are absent, and where, consequently, the symptoms in question cannot be referred to such a lesion." In the latter case he thought, as did also Dr. Macdonnell, that the pus was the result of a vicarious secretion from the bronchial membrane, the action of a sort of reciprocity between the serous and mucous surfaces. Dr. Macdonnell draws a very proper distinction between the symptoms in the two groups, which I think holds good in the majority of cases. When a bronchial fistula is established a large quantity of pus is expectorated with violent and sudden paroxysms of coughing, the quantity at times being so great as to cause suffocation; whereas when no distinct fistula is established, but the pus soaks through the spongy lung substance, the expectoration, though amounting to many ounces in the twenty-four hours, is spat up gradually and in small quantities at a time. This latter mode appears to be not uncommon, it is decidedly more frequent than the development of a bronchial fistula, and a large proportion of the patients recover, sometimes with great rapidity. We have had several instances in the hospital during the past few years, and when I mentioned the subject at the Medico-Chirurgical Society three or four instances were narrated by members. Perforation of a bronchus and the establishment of pneumothorax is not always fatal. Attimont, in his essay,² collected ten cases of recovery after expectoration of the empyema, and some of these were undoubtedly cases of bronchial fistula.

One other point in connection with this case is worth noting. You remember that when the effusion was disappearing, a very fine crepitant râle was heard with inspiration, at the angle of the scapula. It was as fine as, and resembled closely, the pneumonic crepitus. In two other cases of pleurisy I have observed the same phenomenon as the effusion was absorbed, and was not a little puzzled. Dr. Macdonnell, already referred to, also noted this, and described it in another paper, "On the Occurrence of Crepitus in Lung after the Absorption of Pleuritic Effusion."³ Is it, however, in the lung? I mentioned to you at the bedside that it might be *pleuritic*, due to the contact and friction of the two surfaces after the absorption of the fluid, and if so it is in corroboration of the views of Dr. J. R. Leaning, of New York, who holds that the pneumonic crepitus is not a pulmo-

nary but an interpleural sound, due to the friction of the sticky surfaces.

The patient before you, who has been in hospital a few days, illustrates a very different process, but one which is leading to a satisfactory termination.

CASE II.—*Empyema of seven months' standing; absorption of the fluid with retraction of the chest; local perforations of the pleura and subcutaneous abscesses.*—

A. B.—, aged twenty-three, from the Eastern Townships, of good stock, and always strong and healthy. Gives the following history: Quite well until November last, when, while lifting a heavy stone, he felt a stabbing pain in the right side, which continued at intervals for two weeks, during which time, however, he was able to get about and do work. He then took to bed, got weak and feverish, particularly at night. Had chills, and often sweated a great deal. Slept on the left side as a rule; when on the right the pain was increased. Had a cough through the winter; not much expectoration. Lost flesh rapidly. Has not been confined to bed all the time, but got up and went about when he felt able. Latterly he has been improving, cough has disappeared, has no fever or sweats, and thinks he is gaining flesh.

The history points to some chronic chest trouble. When stripped for examination he presents an exceedingly interesting object for clinical study. General inspection shows a tall, bony man, pale and emaciated, and the attention is at once attracted to the lopsided appearance of the body, due to a marked depression of the right shoulder and a decided flattening and shrinkage of the right half of the chest. As he breathes quietly you observe that while the left side expands the right is absolutely immovable, and this is still more marked when he takes a full breath: the left chest expands to an unusual degree, the infra-clavicular and mammary regions swelling out in a striking manner, while the right side remains fixed. From behind the same, flattening and want of movement are noticeable. Closer inspection shows very narrow intercostal spaces on the right side, and in the infra-axillary region there are two flat swellings in the seventh and eighth spaces, and in the latter, also, a fresh cicatrix. The apex-beat can be seen in the fifth space close to the edge of the sternum. There is a croton-oil rash on the front of the chest. Palpation reveals more distinctly the narrowing of the intercostal spaces; the ribs do not appear hypertrophied. The small flat tumors in the seventh and eighth spaces fluctuate, and do not appear to communicate with each other. He states that one has already disappeared, and a fourth was opened and discharged about a spoonful of pus. He has noticed them for a couple of months. Tactile fremitus is marked in the upper part of the right side; below there is no special intensification. The edge of the liver can be felt at the costal border. Mensuration shows the right half of the chest to be nearly an inch smaller than the left, not as much as you might suppose on inspection, but the eye is in this matter very apt to be deceived. Percussion gives in front, on the right side, a flat, somewhat tympanitic note as low as the nipple, flat below this, and absolute dullness behind. The left lung is everywhere resonant. On auscultation, the breath-sounds are absent in the dull regions below, feeble in the supra-scapular and infra-clavicular regions, and on deep inspiration a few râles can be heard. Vocal resonance is much intensified on right side, particularly in places. The examination of the abdomen reveals nothing special; the liver is not enlarged. General condition during the three days he has been in hospital has been good. Eats and sleeps well; has no fever; pulse about 80. A needle was thrust into the eighth interspace behind, but no fluid was obtained. There is laudable pus in the small flat tumors. He does not wish them opened, and returns home to-day. With good food, fresh air, and tonics, he will continue to improve. If the small abscesses remain, his attending physician will open them, but they may disappear, as one has already done. He

¹ Loc. cit.

² Considerations sur les Résultats de la Paracentèse, etc., 1869.

³ Dublin Medical Journal, 1845.

will recover, with a damaged lung and shrunken side; but with compensatory enlargement of the left, and a gradual improvement and distention of the upper part of the right lung the respiratory area will be amply sufficient for the purposes of an ordinary life.

As to the diagnosis in this case—could you mistake it for anything else? The only other affection which produces a somewhat similar condition is fibroid phthisis or cirrhosis of the lung, in which there may be the depressed shoulder, flattened and contracted chest, with immobility, dulness, and weak breathing, but the history would be one of long-standing lung trouble, and there would be cough, expectoration, and special auscultatory signs. With the local abscesses perforating the intercostal spaces, the diagnosis in this case is, at present, easy enough; but some years hence, when these have disappeared and nothing is left but the retraction, dulness, and feeble breathing, it might not be so easy without a full history. The condition of this man's chest illustrates in another way what nature can do in effecting a cure when an empyema is not interfered with. The effusion has evidently been pretty copious, and as the weeks and months elapsed became more concentrated and has gradually been absorbed, until now there is probably not more than a few ounces left. With the disappearance of the fluid another change has gone on; the flaky membranous exudation covering both layers of the pleura has become organized and converted into a dense fibrous tissue which may have a thickness of from half to one inch. In the process of absorption pockets of pus may have been left between the thickened pleural membranes, and sometimes this pus becomes caseous or even cretaceous. The angle between the costal and diaphragmatic layers of the pleura may be filled with a wedge of solid fibro-cartilaginous tissue which defies all attempts to separate it from lung or diaphragm. The firmness of these old pleuritic membranes is extraordinary, and in the removal of the lung, in such a case, the only way is to strip off the costal layer and take the attached portion of diaphragm. The dulness in front and behind in this patient's right side is due chiefly to these thickened membranes, and corresponding to the seventh and eighth interspaces there are small pockets of pus, perhaps isolated, as they often are, and communicating by sinuses with the small external tumors. The lower lobe of the lung is condensed and airless, the upper and middle lobes, though thickly coated with false membranes, probably contain a good deal of normal and functionally active tissue. What produces the great deformity? When a sero-fibrinous fluid is absorbed, or after its withdrawal by aspiration, the lung expands, and although, as you have had several opportunities of observing, for months after there may be basic dulness and defective expansion, there is no retraction. In chronic pleurisy, however, the serous layers are unusually thickened, the false membranes organize, and there is produced a large amount of new connective tissue, which gradually shrinks, prevents the expansion of the lung, and little by little drags in the side, narrows the intercostal spaces, pulls down the shoulder, may curve the spine, and displaces contiguous organs, drawing the heart over and the liver up, until there is presented such a typical condition of *rétrécissement thoracique* as exists in this case. Although the shrinkage and condensation of the organized membranes play the most important part in the process, some share must be attributed to other agencies, such as posture—the patient favoring the affected side—atmospheric pressure, and muscular contraction. Will this side ever expand again? Not to its full extent or near it. In time the upper regions of the lung will dilate more fully and there will probably be some movement in the anterior part, now absolutely quiet, but the deformity will remain and the lower part of the right side will never expand. It is true that occasionally a remarkable amount of expansion may take place after a *pleuritis deformans*. Sir Thomas Watson refers to two examples of complete re-expansion of the

side, contracted after chronic pleurisy, but such cases are extremely rare.

Perforation of the costal pleura and the formation of a subcutaneous abscess constitute the condition known as *empyema necessitatis*, which is not often seen. In this instance the external collections are small, and probably connected with encapsuled *deposits* within the pleura. One has already disappeared, and a second, which was opened, healed rapidly, and the two which remain are not connected with each other, and probably not with any large amount inside. There are two or three points of interest about *empyema of necessity* to which I will refer as you are not likely to see another instance of it for some time. When it breaks, or is opened, the fistula which forms may remain for years and be difficult to heal. There is a case on record of one Dr. Wendelstadt, a Bavarian, who had such a fistula for over thirteen years and enjoyed fairly good health. Necrosis and caries of the ribs are apt to occur and retard recovery, as the sinuses which result run in various directions and are very difficult to heal. A case of the kind occurred a year or so ago in the practice of Dr. Rodger, of this city, and at the autopsy we found the skin and pleura of the antero-lateral region on the left side riddled with sinuses communicating with carious ribs and small pockets of pus within the thick layers of false membrane. Occasionally in *empyema necessitatis* the external tumor pulsates synchronously with the heart, and might be mistaken for aneurism. This was the result of a communicated cardiac pulsation, and was first described by Dr. Macdonnell, in the paper already referred to, and not by Dr. Walshe, to whom the credit is usually given.¹

Progress of Medical Science.

KAIRIN, THE NEW ANTIPYRETIC.—We have already called attention to a newly described drug, which has been italicized by Hallepeau as that which “of all antipyretic agents is in non-toxic doses the most certain, the most powerful, and the most rapid in its action.” This drug is a methyl hydrate of oxyquinoline, having the formula $C_{10}H_{13}NO$. It is derived from quinoline and exists under two forms known as *kairin* and *kairin M.*, the latter being that which has been most extensively used. It was first introduced to the notice of the profession by Dr. W. Filehne, Professor of Physiology at Erlangen, who asserted it to be a most powerful antipyretic, not only in typhoid and other continued fevers, but in all febrile conditions, including pneumonia, phthisis, and acute rheumatism. The drug exists in the form of a grayish-yellow, crystalline powder, easily soluble in water, and of a bitter, aromatic, somewhat disagreeable taste. The method of giving it, as described by Filehne, is as follows: Doses of thirty to fifty centigrammes must be administered every hour or hour and a half. After the first dose, the temperature falls about one degree, and after the third or fourth dose, it has reached the normal. The defervescence is accompanied with sweating, but the pulse remains full and the patient feels well. If now the drug is at once discontinued, the temperature rapidly rises, and the patient very likely experiences a chill. In order to prevent this, the *kairin* is continued in smaller doses of twenty-five centigrammes, frequently repeated, *i.e.*, as often as every three-quarters of an hour. The temperature then slowly rises, but with no disagreeable symptoms. In feeble subjects smaller doses (six to twenty-five centigrammes) will produce apyrexia, while in others even larger amounts than those first named are required. The drug appears generally to be well tolerated, but it sometimes causes vomiting and headache. It is eliminated by the kidneys and gives the urine a green color. Since Filehne's first article it has been used

¹ The mistake has arisen from the fact that Dr. Walshe has described two remarkable cases of intra-pleural pulsating empyema.

by several other observers, who all confirm the first statements regarding its powerful antipyretic effect. Freymuth has made some particularly interesting studies of its action in relapsing fever. He found that although it rapidly reduced the temperature it had no effect upon the movements and form of the spirilli, showing that the production of apyrexia and the destruction of the infecting germs were two different things. Given in proper doses, the relapses could be prevented. Freymuth found, however, that in several cases, gastric disturbance and prostration were so great that the remedy had to be discontinued. Hallopeau has recently announced his experience with kairin. He employed it in two cases of lobar pneumonia and in one of phthisis. Temperature charts are given, showing that the drug acted rapidly and powerfully in all these cases, and Hallopeau thinks its remarkable antipyretic power to be demonstrated. The question whether the apyrexia thus produced is always desirable is another matter which still remains to be settled. Filehne has recently made two further communications in which he gives directions as to the dosage of kairin, and states that there are two very similar bodies, kairin and kairin M. The latter, has, as we mentioned, been chiefly used, but Filehne believes the former to be somewhat more enduring and agreeable in its actions. Still more recently, Guttman has reported his experience with kairin M. to the Berlin Medical Society. He had employed it in seventy cases. His experience confirms in a measure that of previous observers, but he does not speak with enthusiasm as to its effect upon the course of the disease. Riess, who has used kairin in eight cases, thinks it of less value, on the whole, than quinine or salicylic acid, but he admitted that his experience was too limited for him to speak positively.

ANTAGONISM BETWEEN PARALDEHYDE AND STRYCHNINE.—Professor Vincenzo Cervello concludes from a series of experiments made upon animals that paraldehyde will prevent the appearance of toxic symptoms of strychnine if it is given before they have manifested themselves, and will cause them to subside if they have already appeared. This antagonism is manifested in any case, whether the paraldehyde be given before or after the strychnine or at the same time with it. But the converse of this does not appear to be true. Strychnine seems to exert little or no influence over the narcosis of paraldehyde. The phenomena caused by the latter drug seem to predominate, the only effect of strychnine being a retardation in the appearance of the paraldehyde symptoms. From another series of experiments, the author was led to think very highly of paraldehyde as a narcotic. The drug, in his hands, always caused a tranquil sleep, preceded by no period of excitement, during which the respirations were quiet and somewhat slower than normal. The patients complained of no headache, nausea, or any other unpleasant symptoms upon awakening from the paraldehyde sleep. Professor Maselli has met with like favorable results in his use of the drug. He has employed it in over three hundred cases of neuralgia, mental diseases, and other affections in which insomnia was a distressing symptom, and has found great satisfaction in its use.—*Bulletin Général de Thérapeutique*, August 30, 1883.

THE RATIONAL TREATMENT OF DYSENTERY.—In an article of some length in the *Bulletin Général de Thérapeutique* of June 15, 1883, Dr. Kobryner enters a protest against the so-called specific treatment of dysentery by ipecac. He thinks that this drug is seldom of any value in the treatment of this affection, and that often it does positive harm. The proper treatment, he thinks, consists in fulfilling the indications presented by the disease, and not in the routine method, based on pure empiricism, of forcing down immense doses of ipecacuanha. There are, he argues, five special indications to be followed in the treatment of the grave forms of dysentery. The first is to rid the patient of everything that may aggra-

vate or keep up the morbid condition. This end is to be attained first by the administration of an emetic. In the milder cases this is not necessary, as the onset of the disease is usually preceded by a longer or shorter period of general malaise, when there is but little appetite. The patient eats only a little light food, and the stomach consequently is nearly or wholly empty. In dysentery of severe type, on the contrary, especially in times of epidemic, the invasion is sudden, and the patient may be seized shortly after the ingestion of a full meal. The process of digestion is suddenly arrested, and the stomach must be relieved of its load as speedily as possible. Then the rest of the digestive tract requires attention. The intestines are filled with a quantity of fecal matter which must be got rid of. This is to be accomplished by the administration of any of the ordinary salines or laxative mineral waters. In mild cases this is all the treatment usually required. The second indication is to moderate the fever. This end Dr. Kobryner attains by a restricted diet. When the fever is high the fast must be absolute, but as soon as it begins to fall some light soup may be allowed. Solid food is not allowed until the patient is absolutely free from fever. Infants at the breast may be permitted to nurse, but must take only a little milk at a time. They should not be urged if they refuse the breast. In bottle-fed infants, milk is not allowed, but they can have only light broths and a little albumen and water. The third indication is to relieve the colic. While opium is the specific for pain, it is not to be thought of in dysentery. Notwithstanding all our efforts to unload the bowels, it often happens that hard fecal masses are expelled from time to time, and if opium is given they are retained and increase the irritation. The remedy for the colic of dysentery is calomel. In spite of its ordinary action in increasing the intestinal discharges, it relieves the pain, and, in this case, diminishes the number of the dejections. The fourth indication is to restore the blood to its normal richness. This is a most important part of the treatment, and is best accomplished by perchloride of iron in doses of eight drops per diem for nursing infants, and a proportionate amount for older patients. In addition to this may be given a drink of white of egg in water (the whites of six or eight eggs to a quart of water). It is not until the sixth or seventh day that the signs of impoverishment of the blood become evident, so that the treatment by iron and albumen is not to be begun until that time. The last indication, which is met with in only a certain proportion of cases, is to treat the intermittent character of the symptoms. Quinine is the remedy here.

GANGRENE OF THE LOWER EXTREMITIES FROM OB-LITERATION OF THE ABDOMINAL AORTA.—Dr. Gyselynck reports in the *Archives Médicales Belges*, for August, 1883, the case of a man, twenty-three years of age, admitted to hospital suffering from palpitation of the heart following an alcoholic debauch. The pulse was beating about two hundred times a minute, though it was impossible to count it exactly. There was oppressed breathing and slight cyanosis. There was no improvement for five days, notwithstanding an active treatment by digitalis and blood-letting. At the end of this time the pulse suddenly fell to 64, but was intermittent. There was at this time a coldness of the feet and legs with anæsthesia. The coldness continued, gangrene of the entire lower extremities ensued, and the patient died after four weeks of suffering. At the autopsy, the abdominal aorta was found completely obstructed by a large clot situated a little above the bifurcation. There was an ulceration of the inner coat of the artery in this situation, and the supposition was that the thrombus arose from a deposition of fibrine and leucocytes at this point.

THE MENTAL CONDITION OF CERTAIN DIABETICS.—In some subjects of diabetes, states *Le Practicien*, certain changes in the moral nature are so marked as to point to a correct diagnosis before an examination of the

urine has been made. A young man who, in consequence of this disease, has lost his virile power will state the fact of his impotence to his physician with a sort of indifference, very different from the anxious fear displayed by the hypochondriac under like circumstances. At a more advanced stage of the disease, when the quantity of sugar in the urine is considerably augmented, the mental state changes. The patient becomes sad and is the prey of hypochondriacal forebodings. His character changes; from being free and open-hearted he becomes morose and moody, speaks but little and smiles less. He becomes parsimonious, and tries to cut down the expenses of his household, begins to keep exact accounts, calculates his resources, and declares that he is ruined and that his family will die in the poor-house. The man of middle age who, without apparent cause and without exhibiting any other mental disturbance, becomes all at once avaricious and presents delusions of rapidly approaching financial ruin, is most frequently a diabetic. If these melancholic forebodings continue, and if on examination the presence of sugar in the urine is established, the chances are that the patient will end his life by suicide. In the later stages, after the disease has existed for some length of time, still another mental condition is noted. The patient is lazy and wants only to be let alone; he will spend hours sitting in his arm-chair or lying on his lounge in a state of complete mental and bodily inactivity; his mind is clear, and his intelligence is unimpaired, but he is apathetic, he has no desire to walk or to talk, and seeks no occupation. Later, while preserving all his mental faculties intact, he begins to indulge in soliloquy, and relates incidents and recalls old memories to himself in an undertone. Finally, he falls into a state bordering on marasmus, and is carried off usually by that most grave of the complications of diabetes—pulmonary phthisis.

CEREBRAL DISEASE FOLLOWING POISONING BY ILLUMINATING GAS.—A man, fifty-six years of age, of previously good health and free from hereditary taint, was asphyxiated by coal gas. He recovered from the physical effects, but suffered from insomnia, weakness of memory and depression, and was unable to pursue his former occupations. Later, he had auditory illusions and refused to take food. The only motor disturbance was a facial paresis on the right side. Toward the end the patient was ataxic and had a tendency to fall forward while walking. Death was sudden and resulted from a fracture of the ossified thyroid cartilage. The autopsy revealed a spot of yellow softening, the size of a bean, in the corpus striatum on each side. This involved the inner portion of the nucleus lenticularis and the internal capsule. Dr. R. Gnauck, who reported the case (*Wiener Medicinische Wochenschrift*, September 1, 1883), regards as worthy of note the fact that such a lesion gave rise to no marked motor disturbances. He states that three other cases have been reported by Lesser of a similar lesion due to a like cause.

LOW TEMPERATURE IN CACHECTIC CONDITIONS.—Dr. P. Lucas-Championnière relates in the *Journal de Médecine et de Chirurgie Pratiques* for September, 1883, the case of a child suffering from erysipelas, in which there was not only no fever, but even a notably reduced temperature. The thermometer registered only 91.5° F. He calls attention to the case as illustrating a fact of considerable importance, namely, that in certain cachectic conditions, inflammatory affections which are ordinarily accompanied by considerable fever may run their course without determining any such reaction, or may even provoke a reduced temperature. One should not, therefore, be prevented from making a diagnosis in such a case because of the absence of fever.

CHROMIC ACID IN AFFECTIONS OF THE MOUTH.—Dr. Cauquil, writing to the *Bulletin Général de Thérapeutique*, No. 12, vol. civ., concerning the employment of

chromic acid, as recommended by Dr. Butlin in diseases of the tongue, states that he has also found it of value in stomatitis. He has used it with success in mercurial sore mouth, in the strength of one to five. In other cases of syphilitic pharyngitis with hypertrophy of the tonsils he has obtained good results with the same solution.

INHERITANCE AS A CAUSE OF DRUNKENNESS.—In support of the theory of the hereditary transmission of the thirst for alcohol, Dr. J. S. Jewell related the following remarkable instance at the meeting of the California State Medical Society (*Pacific Medical and Surgical Journal*, September, 1883): The patient was the third son of his parents, and was sorely afflicted with alcoholism. He stated to Dr. Jewell that himself and younger brother (the fourth son) had always, almost from infancy, been too fond of liquors, while his two elder brothers were strong total abstinence men, and never touched liquor; the latter were also men of wealth, while the younger, who were inebriates, were poor. He said that he had often heard his mother say of his father, that during the first five years of their married life he (the father) did not use liquor in any way, and would not associate with men who did. But about the fifth year after their marriage, about the time the third son was begotten, the father had many business reverses, took to drink, and died after being an habitual drunkard for several years.

DISLOCATION OF THE HUMERUS FROM SNEEZING.—Dr. William Rickert reports in the *Maryland Medical Journal*, for September 29, 1883, the case of a man, who while cleaning a house, felt an inclination to sneeze. He stopped work and, raising his left arm above his head, supported himself with the other hand against the side of the stable. While in this position he sneezed, and immediately felt that something was wrong with his shoulder. Examination showed an infraclavicular luxation of the head of the humerus, which was quickly reduced under anæsthesia.

THE PATHOLOGICAL CHANGES IN GONORRHOEA.—Professor Hamilton, of Aberdeen, has had an opportunity to examine microscopically the condition of the urethra in acute gonorrhœa (*The Practitioner*, September, 1883). The epithelium of the urethra is disposed much as in the bronchus, in three strata—the deepest of flat cells, the middle of pear-shaped cells, and the superficial of columnar cells. In acute gonorrhœa the process consists mainly in an exaggerated and irregular proliferation of the deeper strata of cells, the cell-production being so rapid that the discharge contains but few of the fully developed columnar forms. The denudation of the surface in this process explains the scalding pain on micturition. The secretion of the mucous glands is increased, as in bronchial inflammation. There is also considerable corpuscular infiltration of the mucous membrane, leucocytes being accumulated in the sub-epithelial lymphatic spaces; and although there does not exist an elastic basement membrane, which, according to the author, prevents the escape of these interstitial products on to the free surface in bronchitis, he nevertheless doubts if that occurs here, believing rather that the cellular exudations in the meshes of the mucosa are carried away by the lymph stream. There was not in the specimen any marked congestion of the blood-vessels; and the trabecular tissue of the penis was not abnormal unless accumulated leucocytes in the cavernous spaces may be so considered. Strictures are produced in chronic urethritis probably by the submucous tissue becoming cirrhotic and contracting upon the lumen; the absence of "fixed joints" indicating the difference in results from chronic bronchitis when the tubes are dilated. The tubules of the testicles and of the epididymis from the same case also showed marked catarrhal inflammation, being filled with debris and epithelial cells in all stages of disintegration, but there was no interstitial inflammation whatever.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, October 20, 1883.

TRANSFUSION OF BLOOD AND INTRA-VENOUS INJECTIONS OF SALINE SOLUTIONS.

TRANSFUSION of blood seems to have originated with Lewer, of England, whose work, about the year 1666, records several experiments performed on dogs, into whose veins arterial blood from other dogs was made to flow by direct communication of the divided vessels. In 1667, Emmerez, of Montpellier, France, performed transfusion on a patient of Denis, injecting into the vein of the sick man nine ounces of lamb's blood; the patient was in extreme prostration from typhoid fever, but recovered; his recovery being attributed to the operation. In 1668, transfusion was performed in Italy, by Fracasati, Riva, and Manfredi, on human subjects, the donors of blood being healthy men. The first signal successes of transfusion awakened great hope in the operation, and it was speedily resorted to for a great variety of disorders. In accordance with the prevalence of humoral theories of pathology it was supposed that the whole mass of the blood might easily be renovated by supplying to the diseased individual the pure blood of healthy men, or even animals; even madness, it was alleged, might be successfully combated by transfusion. As a result of this infatuation the practice was speedily abused, was continually followed by disaster and death, and leagues were formed against it. In 1675 transfusion was proscribed in France by an Act of Parliament. For almost a century and a half transfusion was completely abandoned, to be taken up anew about the year 1815 by Blundell, who recommended it in cases of extreme debility from hemorrhage or wasting disease. Blundell, whose "Researches, Physiological and Pathological, on Transfusion," appeared in 1824, advised to perform the operation by means of a syringe which should take up the blood from a cup into which it was made to flow, and inject it directly into the vein of the patient. Diefenbach, in 1828, was the first to employ the terms *mediate* and *immediate* transfusion; *mediate*, when it is done by means of a syringe, and *immediate* when the artery of one animal is made to communicate directly with the vein of another animal. He was also the first to use defibrinated blood. Since then the operation has been very much perfected by means of the instrumental apparatus of Moncoq and Belina, as improved by Charrière, Collin, and Mathieu. These, however, have the disadvantage of allowing air to be admitted to the blood of the donor before it is injected, an evil which is remedied

by the more complex transfusion instruments of Schliep, Neudorfer, and especially Roussel.

It is not our purpose in this article to discuss the advantages or disadvantages of transfusion of blood. Suffice it to say that experience has proved that whether whole blood be used or defibrinated blood, serious accidents may result from the operation, however great the care and expertness of the operator—and death has not seldom happened while the transfusion was going on from blood-clotting, or from the penetration of air. It has been shown that but a small part of the product of transfusion can be assimilated; the globules of the donor of blood, whether animal or man, rapidly undergoing dissolution in the serum of the individual whose circulatory system became their new habitat. Ponfick and Sardeis have shown that this solution is the more rapid, the greater the difference in the animal scale between the species whose sanguinous fluids are mixed. Veritable embolic infarctions are likely to occur from the agglutination of heterogeneous corpuscles. Despite every precaution air will sometimes penetrate along with the blood, although this accident is much less likely to happen with the improved modern apparatus above mentioned. Fever, hæmaturia, even albuminuria have followed cases which proved successful—an expression of the difficulty which attends grafting one kind of blood on another. Even defibrinated blood is not free from these dangers. Landois has shown that whipping blood to free it from fibrin does not, to any great extent, clear it of corpuscles, and De Christoforis affirms that the globules remain whole and sound notwithstanding the beating. To obviate the inconveniences and dangers from the use of blood, whole or defibrinated, intravenous injections of milk have been proposed, and of saline solutions. The intravenous injection of milk has a curious and instructive history of its own, which we have not time now to pursue. Suffice it that it has been attended with several remarkable successes, as practised by Hodder, Joseph W. Howe, T. Gaillard Thomas, Wm. Pepper, and others, and is believed to give as satisfactory results as transfusion of blood. At the same time it is by no means free from danger, and Culcerq has shown that the fatality attending these injections is due to the formation of fatty emboli, from agglomeration of the milk-corpuscles.

The intravenous injection of saline solutions has of late come into vogue as a safe and efficient substitute for transfusion of blood. This practice originated with the earnest attempts of physicians to combat the cholera during the epidemic of 1830. Janichen, of Moscow, Latta, of Scotland, and Magendie, of France, are credited with having successfully performed saline transfusions about this epoch. It was believed, and the result justified the theory, that the algidity and other fatal accidents of cholera were due to the too great elimination of serum in the stools, hence the indication presented itself to inject an artificial serum to supply the place of the serum that was lost. These saline injections have been practised in Asiatic cholera more or less often since that period; sometimes successfully, at other times with only a passing amelioration, but nothing has ever occurred to indicate that any danger attended their use.

This very year Dr. O. Jennings, of London, has taken up the subject in an able monograph on transfusion,

urging the general introduction of intravenous saline injections in all cases where heretofore transfusion of blood has been supposed to be indicated. A year or so ago Bischoff reported a case of post-partum hemorrhage, where the patient, in a state of complete collapse from loss of blood, was restored by the injection into the peripheral extremity of the divided radial artery of two hundred grammes of a six per cent. solution of common salt. This solution was rendered alkaline by the addition of two drops of liquor potassæ. The injection was slowly made, the whole time occupied by the operation being an hour. During the transfusion the patient, previously cold and moribund, revived, the pulse came back, and at the end of the transfusion was only 122 per minute. There was no symptom of oppression, such as is generally witnessed during the transfusion of blood.¹

This very year Szamann has reported a similar case, in which the intravenous transfusion of a weak saline solution, made slightly alkaline by a little liquor sodæ, undoubtedly rescued a woman from the agonies of death from uterine hemorrhage.²

From the *Bulletin Gen. de Thérapeutique* (tome cv., 3d liv., p. 125) we obtain the details of an interesting case reported by Heyden, which is very similar to those of Szamann and Bischoff above referred to. A glass funnel was used, connected with a simple gutta-percha tube, ending in a metallic canula, which was made to penetrate the median vein, in which it was tied. In the space of five minutes fifteen ounces were injected of a saline solution consisting of six grammes chloride sodium, twenty drops of liquor sodæ, and one litre of distilled water. (This is the solution of Schwarz.) A period of calm followed in which the pulse regained its force and became slow, and the extremities became warm. In the course of an hour the patient (previously unconscious) came to herself, and made a rapid recovery.

The credit of this method of transfusion of saline solutions has been wrongly assigned to both Little and Schwarz, who really did nothing but improve on an old method. The merit of Schwarz consists in having based this operation on a special theory of the action of the transfused liquid, which experience has confirmed. This theory is succinctly set forth by the review writer in the number of the *Bulletin de Thérapeutique* above alluded to. In cases of profuse hemorrhage the resulting fatality has been attributed to the loss of the requisite number of blood-corpuscles. The oxygen of respiration, not finding a sufficient number of carriers, reaches the nerve-centres in far too small proportions, and life was extinguished, with the heart's action, from want of oxygen. Such being the theory, it was natural, in order to remedy these accidents, to supply new globules to the blood; hence transfusion found justification. The corpuscular element was the useful and all-important one.

The blood-corpuscle, says Schwarz, is in no sense the useful element in transfusion, and he has proved it by bringing to life numerous hares bled to syncope by injecting into their veins the solution whose formula we have given above. The useful element is the vascular tension; the heart does not perform its function, does not contract unless a sufficient quantity of fluid is poured

into its cavities, and this fluid must be under a pressure sufficient to bring into play the contractile energies of the heart. Inject, then, into the venous system an alkaline liquid homogeneous with its serum, and re-establish the vascular tension, you will restore activity to the circulation and will prevent the production of fatal accidents. According to Schwarz, then, it is not the quality of the liquid injected, but the quantity which is of real importance.

If the theory of Schwarz shall prove to be true (and the facts which are above given are strikingly demonstrative), a great future is in reserve for the intravenous injections of saline solutions, which must supersede the more ancient sanguineous injections; such transfusion being attended with much less difficulty and less danger.

THE TRANSMIGRATION OF BACTERIA FROM THE MATERNAL TO THE FETAL CIRCULATION.

CONSIDERABLE attention has been called of late to the possibility of the passage of micro-organisms from the maternal blood to that of the foetus through the placenta. Truzzi and others have published the results of some experiments made by them in vaccinating pregnant women to determine whether the children born of them would be likewise protected. They found, however, in every case that the children responded readily to vaccination performed a few days after birth, thus demonstrating either that the micro-organism of vaccinia was unable to pass through the placenta, or else that it was so modified in its passage as to have lost its power of reproduction. It has further been shown that the placenta offered an impassable barrier to mineral substances reduced to a very fine powder and introduced into the maternal circulation.

The motionless rods characteristic of malignant pustule have never been found in the blood or other tissues of a foetus taken from a woman dead of this disease. But in the affection called *charbon symptomatique*, the bacteria in which are endowed with independent movements, the transmigration through the placenta has been ascertained to occur. Dr. Chambrelent, of Bordeaux, in a series of experiments conducted in the laboratory of the *Faculté de Sciences*, has studied the action of the extremely minute bodies described by Pasteur as characteristic of chicken cholera. These organisms, according to the latter, resemble very closely in their size and characteristics, the microscopic granules of small-pox and vaccinia. His method was as follows:

A culture fluid, whose extreme virulence was previously determined by experiments upon a chicken and a rabbit, was used in the inoculation of a number of pregnant rabbits. The animals all died within twelve hours. Other rabbits and chickens were then inoculated with blood taken from the foetuses which were carried by the poisoned rabbits. The results were not uniform. The presence of the characteristic granules in the blood of several of the foetuses was incontestible, and inoculations of this fluid brought about a fatal result. But death in these cases was longer delayed than when the blood of the mothers was used. Others of the foetuses seemed to be unaffected, as inoculations practised with their blood and with culture fluids made from it were followed by negative re-

¹ Centralf. f. Gyn., 1881, p. 545.

² Berliner klin. Woch., July, 1883. Med. News, August 25, 1883.

sults. M. Chambrelent concludes from these experiments that the microbes of chicken-cholera may pass through the placenta, but that they are contained in much smaller number in the blood of the fœtus than in that of the parent. As regards the latter part of his conclusion, the question remains whether this diminished number is due to the partial barrier offered to their transmigration by the placenta or whether the fœtal blood is a less suitable fluid for the reproduction and multiplication of the microbes. According to a writer in the *Gazette des Hôpitaux* it would seem that the latter solution is the correct one. For it is not so much an explanation of the reduced number as of the retarded action of the microbes that is sought for. The action of a small number of micro-organisms in a given fluid is as speedy as that of a large number, provided their virulence be unimpaired. The cause of this modified virulence he finds in the diminished proportion of oxygen contained in the fœtal blood. The microbes of chicken cholera, as those of variola and its allied affections, require a large quantity of oxygen for their full development. This they cannot obtain in the fœtal circulation, hence their attenuation in this fluid. This theory might serve also to explain the failure of Truzzi's experiments with vaccinia. It was not the placenta that impeded the passage of the microbes, but the blood of the fœtus that refused them sustenance. The variolous organisms, already profoundly modified and weakened before their introduction into the maternal circulation, found no incentive to development in the poorly oxygenized blood of the fœtus, and hence became inert and died. Very different is the action of the fully developed microbe of small-pox, which so often kills the fœtus even though it spares the mother. It is strong, and its development is not entirely repressed for want of air.

If this theory be correct, the question suggests itself whether it would not be possible, through culture in an atmosphere rich in oxygen, to restore the strength of the cow-pox granules so that they would again produce variola.

INCINERATION.

In an article in the September number of the *Princeton Review*, Mr. John D. Bengless has presented, in an able and candid manner, the arguments in favor of cremation. The United States Cremation Company has republished this article and is using it in the propaganda of its faith.

The arguments presented by Mr. Bengless are not new, but perhaps the economical side of the matter has not been presented so forcibly heretofore. The total average cost of burial in New York City is estimated to be not less than two hundred and fifty dollars, while the expense of cremation will be only about sixty dollars, including an urn and a niche in the Columbarium. Mr. Bengless also affirms that there will be no trouble in cremating all the dead of large cities by means of the "octuple crematory" of Bombay, or the "multiplex portable incinerator" of Brussels, which we confess are new terms in mortuary technology.

We have said before that cremation has not taken well in this country, and that there was nothing to deplore in the fact. It can doubtless be made a useful mode of

disposing of the dead in many cases, yet we do not think that either sanitation or sentiment demand it; and in many parts of the country it will be a long time, if ever, before it can be made practicable or economical.

TRAINED NURSES FOR THE COUNTRY.

WE have received a letter from a correspondent calling our attention to the need of trained nurses for the country. It is urged that neither country physicians nor their patients yet appreciate the help they can receive from this class of persons.

It cannot be doubted that more and better nurses are needed and could be employed in the rural districts and small towns. It takes some time for the profession and the public to be educated up to an understanding of the increased effectiveness of medical skill when assisted by intelligent nursing. Still this knowledge is rapidly growing, and perhaps as fast as could be expected. We have already over twenty training schools in this country which are yearly sending out numerous graduates. These for the most part remain in the cities, where the pay is better and employment more regular.

It will not be long, however, before our cities are supplied, and we believe that the country will furnish an excellent field. The pay here must be smaller, but it will be more than is usually paid for teaching the district schools, and the expenses of living make it possible to save as much as if one were receiving higher wages in the city. We trust that our country practitioners will encourage as much as possible the importation of trained nurses among them.

News of the Week.

THE NUMERICAL STATUS OF THE CODE CONTROVERSY.

—Some misapprehension exists as to the exact state of affairs regarding the Code controversy, owing to the misleading statements of some of our out-of-town contemporaries. There are in the State of New York 10,000 physicians (in 1880, 9,272), of whom the homœopaths claim 1,000. Of the remaining 9,000, there have been 2,403 who have signed a paper upholding the National Code, "until it is changed by the American Medical Association." Many of these, as is well known, signed under the belief that the said association would soon make some change, and not from any antagonism to the principles represented in the State Code. It may be questioned, therefore, if a majority, or even a third of the reputable medical men in this State favor the views and position championed by Drs. Squibb and Flint, Jr., and by our out-of-town contemporary.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.—

The annual meeting of this Society will be held in the hall of the Young Men's Christian Association, corner of Fourth Avenue and Twenty-third Street, Monday evening, October 22, 1883.

CONCERNING A CHARGE AGAINST THE PRESIDENT OF THE ACADEMY.—In a report of the last meeting of the New York Academy of Medicine, in the *Boston Medical and Surgical Journal* of October 11th, there appeared

what seems to be intended as a serious charge against the president of the Academy. Every man of honor would so regard it. The idea is distinctly conveyed, that two names had been used on the notices, one as mover and the other as seconder of the amendments, "without proper authorization," and that they "had declined to serve in this capacity." Both had agreed "to serve in this capacity," and neither declined until after the notice was printed.

We make no comments until sufficient time has elapsed for the writer to correct his statement.

THE INQUEST AS TO THE EPIDEMIC IN THE EAST CHESTER ASYLUM.—The Coroner's inquest in the case of Emma Nicholson, who died at the Mount Vernon Home of the New York Infant Asylum, has been concluded. The jury returned a verdict in substance as follows: "We find that Emma Nicholson died at the East Chester Branch of the New York Infant Asylum, October 5, 1883, from a complication of diseases, the immediate cause of her death being scarlet fever, diphtheria, and pleuro-broncho-pneumonia. Within the last two months fully thirty per cent. of the children in the asylum have died. This fearful rate of mortality, in our opinion, is the result of gross negligence upon the part of those having charge of the medical and sanitary departments, and the lack of attention of the president of the society, acting under the authority of the Board of Management, in appointing a person incompetent of performing the duty required of a physician in charge of such an institution. We respectfully request that immediate steps be taken for the suppression of the epidemic in the asylum. We further request the Coroner to ask the District Attorney of this county if this matter is not a proper subject for criminal investigation."

We think it probable that the above verdict may represent but one side of the case, as we are informed that a competent sanitarian and medical visitors are attached to the asylum.

A NEW MEDICAL JOURNAL.—The first number of the *Medical Student*, edited by William G. Mortimer, with its editorial office in the midst of medical teachings, and especially designed for students preparing for examination, is upon our table, and has a tidy appearance. The two noteworthy articles in this number are a sketch of the life of Prof. William A. Darling, with illustration, and an interesting letter from J. Milner Fothergill.

MEDICAL COLLEGES NOT RECOGNIZED.—At the last meeting of the Missouri State Board of Health, held at Springfield, the diplomas of three of Missouri's Medical Colleges were refused recognition. These colleges were the Joplin Medical College, the Kansas City Hospital College of Medicine, and the St. Joseph Northwestern Medical College.

STAMPING OUT SMALL-POX.—The Sanitary Association met on October 13th, in New Orleans, to confer with the commercial bodies and Cotton Exposition delegates as to the best plan for preventing the spread of the small-pox. A plan for the permanent extinction of small-pox was submitted, providing for the employment of fifteen physicians, at \$100 per month, as sanitary inspectors; ten sanitary police at \$50 per month, and the

appropriation of \$500 for the purchase of vaccine virus and disinfecting material. The city is to be thoroughly inspected from house to house, vaccination tendered, and premises disinfected. Those who decline vaccination are to be listed, with their residences and occupations, for public information. This plan was approved of by the representatives of the Cotton Exchange and Chamber of Commerce, and \$5,000,000 (?) appropriated to carry it into effect.

AN OFFICE THIEF.—A colored boy, a mulatto, about eighteen years old, is going about the city asking to be employed as an office-boy. He is a sneak thief. He gives his name as Henry Harris.

AN AGED PHYSICIAN.—It is reported that Dr. Jackimovicz, of Jarvszinka, in the government of Kiew, Russia, has just died at the age of one hundred and six, and that he was able until nearly the close of his life to superintend the working of an extensive practice.

THE LAWN-TENNIS LEG.—The English journals have reported lately several cases of rupture of the plantaris muscle in lawn-tennis players. Dr. Philpot relates another instance in *The Lancet* of September 22, 1883. His patient stated that while serving a ball with the "cutting-down" stroke he felt as if some one had struck him sharply upon the calf of his leg, and immediately the limb became powerless. A few days subsequently large ecchymoses appeared, not only over the seat of the injury, but on the front of the leg as well, showing probably that the muscle itself was extensively lacerated. Perfect rest for a week till all local symptoms had subsided, and then a starch bandage and a high-heeled shoe, seemed all the interference required.

A PERIPATETIC TEMPERANCE LECTURE.—It is said that Weston, the pedestrian, has announced his intention of undertaking a tour through England and Wales, with a view to demonstrate the superiority of tea over beer and alcoholic drinks in general during periods of prolonged muscular exertion. He proposes to walk fifty miles a day for one hundred days, and at the close of each day's walk to deliver in the town to which his day's journey may have brought him, an address on temperance, having for its title, "*Tea versus Beer.*" He is anxious for medical men of the towns through which he may pass, and in which he spends the night, to visit him, for the purpose of recording the state of his temperature, respiration, pulse, etc. It is proposed to commence his tour on November 5th, and should this date be finally adopted, the task, if successfully accomplished, will be completed on February 28th. As Sunday will be taken as a day of rest, the actual distance traversed each week will be three hundred miles.

UNIVERSITY OF VERMONT.—Mr. John P. Howard, of New York, has offered to rebuild the medical department of this old university at Burlington, giving it large dissecting-rooms, a large hall for its anatomical museum, and a lecture-room for three hundred hearers. The expense will be about \$40,000. He offers to convert the present medical college building into a gymnasium for the university students. The same gentleman rebuilt the main university building last year, and ordered a colossal statue of General Lafayette, who relaid the cor-

ner-stone of the centre building in 1825, to be modelled by Mr. J. Q. A. Ward. This statue was unveiled with appropriate ceremonies at the Commencement of the university last summer. These magnificent gifts, with many others to the town, including an opera-house to the Home for Destitute Children, the latter largely given by himself several years ago, make a summary of \$400,000.

EPIDEMIC OF DENGUE IN EGYPT.—*El Ensayo Médico* states that there was an epidemic of dengue in Egypt at the same time that the cholera was raging. Over thirty thousand persons in Cairo alone were suffering at one time from this painful affection.

THE EXISTENCE OF YELLOW FEVER in Pensacola and in Brewton, Ala., continues to be a matter of dispute among health officials.

FIGHTING TO KEEP THE CODE QUESTION IN THE NEW YORK ACADEMY OF MEDICINE.—A meeting of physicians who are opposed to any change in the present status of the Code question in the Academy of Medicine, was held at Mott Memorial Hall, October 15th. A call had been issued to the effect that it was thought to be of the greatest importance to the welfare of the Academy of Medicine that the proposed amendments to the constitutions and by-laws should be defeated. An invitation was extended "to meet some of the friends of the Academy who are opposed to the passage of these amendments and who desire to put an end to the discussion of codes of ethics in that body." The call was signed by Drs. Alonzo Clark, T. M. Markoe, Abram Du Bois, John T. Metcalfe, and H. D. Nicoll. Dr. Ellsworth Eliot presided, and there were about one hundred physicians present. There was an informal discussion of the proposed amendments of two hours' duration, in the course of which preliminaries were arranged for action on them at the regular meeting of the Academy on Thursday evening.

Reports of Societies.

MEDICAL SCHOOL OF HARVARD UNIVERSITY.

One Hundredth Anniversary, held in Boston, Mass., October 17, 1883.

(By Telegraph to THE MEDICAL RECORD.)

THE celebration of the one-hundredth anniversary of the establishment of the Medical School of Harvard University, and the dedication of its new building on the corner of Boylston and Exeter Streets, commenced this forenoon in Huntington Hall, at 11 o'clock. President Eliot, in opening the exercises, spoke of the three men who founded the School one hundred years ago, amid many trials and discouragements, and from whose modest beginning has grown up the present School with its staff of forty-seven teachers. The speaker alluded to the great advance recently made in medical science, its brilliant future, and the means for its advancement. He then welcomed the guests and benefactors of the School, and introduced "the oldest professor of our School and the youngest, the man of science and of letters, our teacher and our friend, Dr. Holmes." The feature of the occasion was the oration by Professor Oliver Wendell Holmes. He commenced by taking a retrospective glance at the period when the Harvard Medical School began its teachings, and which brought the professional condition of the earlier epoch to

that of the present. He distinctly remembered the Boston practitioner who walked among the dead after the battle of Bunker Hill, and pointed out the body of Joseph Warren among the heaps of slain. Eight years had passed since John Jeffries was treading the bloody turf on yonder hillside. The independence of the United States had just been recognized by Great Britain. The lessons of the war were fresh in the minds of those who had served as military surgeons. Dr. John Warren, a younger brother of Dr. Joseph Warren, who fell at Bunker Hill, was the first to suggest the founding of a medical school in connection with Harvard College, and was the first Professor of Anatomy and Surgery. Those who remembered his teaching had spoken with admiration of the eloquence and enthusiasm with which he lectured. Dr. John Warren was a man of great energy, spirit, and ability. The lectures of the newly-founded school were delivered in Cambridge, until the erection of the building known as the Massachusetts Medical College, in Mason Street, in the year 1815. It was no easy matter for a busy Boston practitioner to deliver a course of lectures in the university town, but Dr. Warren did not ask whether it was easy or not. Benjamin Waterhouse, honorably known for having been the introducer of vaccination into America, was the first Professor of the Theory and Practice of Medicine. Dr. Holmes remembered him well by the scar of the vaccination. His powdered hair and *queue*, his gold-headed cane, his magisterial air and diction, were familiar to him from his boyhood. The first Professor of Chemistry was Aaron Dexter. It was the forming period of that science. Black, Cavendish, Priestley, Lavoisier, were building it up with their discoveries. A course of chemical lectures delivered in Boston or Cambridge at that day was probably, as it certainly was at a later day, very entertaining, and not wholly un-instructive. The apparatus of illustration was doubtless very imperfect in Dr. Dexter's time compared to what is seen in all the laboratories of to-day. We may admire his philosophy and equanimity, therefore, in recalling the story I used to hear about him: "This experiment, gentlemen," he is represented as saying, "is one of remarkable brilliancy. As I touch the powder you see before me with a drop of this fluid, it bursts into a sudden and brilliant flame." Which it most emphatically does NOT do as he makes the contact. "Gentlemen," he says, with a serene smile, "the experiment has failed. But the principle, gentlemen, the principle remains firm as the everlasting hills."

The speaker next referred to the times when he was a student of medicine, and then drew vivid pen-pictures of the medical worthies he had met here and abroad: John Collins Warren, James Jackson, Jacob Bigelow, Walter Channing, Boyer, Dupuytren, Lisfranc, Velpeau, Civiale, Cruveilhier. Two or three waterlogged old professors were moored to their chairs, one of them not so very old, but with a good many ancient barnacles about him, one formidable three-decker. Broussais, with his upper tier of guns still above the water line and banging away at the assailants of his famous "physiological doctrine." What had been the most signal advance in the science and art of medicine between 1783 and 1833? The first half of the century we are considering. In medical science the method of studying the human body by its constituent elements. The general anatomy of Bichat—which is to common descriptive anatomy what geology is to geography, would still hold the first place if it could claim all that the microscope has done for it. It was, at any rate, a great onward movement with far-reaching results for physiology and pathology. Next to this would come the discoveries of Sir Charles Bell and Magendie of the distinct motor and sensitive functions of certain nerves and nerve-roots. The most important practical achievement was the introduction of vaccination. He knew that it had been, and is even at the present day the subject of violent attacks and bitter prejudices. There was always an unconvinced and irreclaimable minority. Those who

believed not Moses and the prophets would not believe though one rose from the dead to convince them.

Laennec's invention of auscultation held the next place to vaccination in the records of practical improvement during our first half century. The recognition of the affection of the kidneys known as "Bright's disease," and the separation of the too familiar and fatal malady, diphtheria, from those with which it was long confounded, are other notable advances made during the period in question. Comparing the two half centuries the following improvements might be balanced against others: Against the discovery of the double nerve-function, the extended knowledge of the reflex function; against "general anatomy," the cell doctrine due to the discoveries by the use of the achromatic microscope to which we also owe the discovery of the minute organisms, so important in the history of disease; against vaccination we may offset surgical anæsthesia; against the stethoscope, the medical thermometer. We must divide the honors of lithotripsy and those of ovariectomy between the two periods. The beneficent changes in the treatment of insanity effected by the earlier labors of Pinel and Esquirol have been admirably carried on in the more recent period. But the last fifty years had not been less productive. Modern chemistry was no longer a mystery of pyrotechnical display; physiology was a new science; anatomy involved the more exact study of regions; operative surgery had achieved the triumph of ovariectomy, resection of joints, paracentesis. In the prevention of disease the gain had been most extraordinary as evinced by the study of the germ theory. The phrase of "drain fever" had saved hundreds of lives.

The practice of drugging for its own sake, the fatal bequest of the English apothecary or "general practitioner," whose profit was made on his medicines, he pointed out to the medical profession of this country, as he believed, when, some twenty and more years ago, in guarded terms, often misquoted, he denounced it somewhat too epigrammatically for some of his friends of the Massachusetts Medical Society. Professor Gairdner, of the University of Glasgow, had recently used language much plainer than his innocent allusion to the probable effect of sinking a car of miscellaneous drugs among the fish. Bleeding was an almost unknown operation. Of the four great remedies of Dr. Holyoke's and Dr. James Jackson's time, antimony had fallen from grace, and calomel, instead of being next the apothecary's right hand, as the letter "e" is to the printer's, has gone to an upper shelf, where it may be supposed to repent of its misdeeds like Simeon Stylites. Cotton Mather had said, a century and a half ago: "I am not sorry that antimonial emetics begin to be disused." He had said, too, more rhetorically, "Mercury, we know thee; but we are afraid thou wilt kill us, too, if we employ thee to kill them that kill us." This was a lively way of putting a thought long afterward made into a famous saying. While old drugs and old methods have become obsolete, new drugs and new methods have come in to take their place. The less the patient is annoyed with over medication, painful and disgusting remedies, the more tractable he is likely to be, and the less likely to throw his medicine out of the window, where it will kill the chickens instead of the fishes, the more attention is likely to be paid to air and cleanliness and comfort, and the more to the kind of nourishment and the modes and times of giving it. In proportion as the worth of the apothecary diminishes, the cares of the nurse are called upon to render disease endurable by all the arts known to a skilful attendant. Little things mean a great deal in the sick-room. "Will you have an orange or a fig?" said Dr. James Jackson to a fine little boy now grown up to goodly stature, and whom he might be fortunate enough to recognize among his audience of to-day. "A fig," answered Master Theodore with alacrity. "No fever, there," says the good doctor, "or he would certainly have said an orange." Now it is just in these little unimportant

all-important matters that a good nurse is of incalculable aid to the physician, and the growing conviction of the importance of the thorough training of young women as nurses is one of the most hopeful signs of medical advancement. So much has been done and is doing that the days of the Sairey Gamps and Betsy Prigs are numbered. I have often wished that disease could be hunted by its professional antagonists in couples—a doctor and a doctor's quick-witted wife making a joint visit and attacking the patient—I mean the patient's malady, of course—with their united capacities; for I am quite sure that there is a natural clairvoyance in a woman which would make her as much the superior of man in some particulars of diagnosis as she certainly is in distinguishing shades of color. Many a suicide would have been prevented if the doctor's wife had visited the victim the day before it happened. She would have seen in the merchant's face his impending bankruptcy while her stupid husband was prescribing for his dyspepsia and indorsing his note. She would recognize the lovelorn maiden by an ill-adjusted ribbon, a line in the features, a drop in the attitude, a tone in the voice, which mean nothing to him; and so the brook must be dragged tomorrow. The dual arrangement of which he had spoken was, he supposed, impracticable; but a woman's advice, he suspected, often determined her husband's prescription. Instead of a curtain-lecture on his own failings, he gets a clinical lecture. On the puzzling case, it may be, of a neighbor suffering from the complaint known to village nosology as "a complication of diseases," which her keen eyes see into as much better than his as they would through the eye of a small-sized needle, she will find the right end of a case to get hold of, and take the snarls out as she would out of a skein of thread or a ball of worsted, which he would speedily have reduced to a hopeless tangle.

The speaker in enumerating the advances made, gracefully and feelingly alluded to the brilliant achievements of Bigelow in crushing stone by a new method and in reducing dislocations by simple and effective manipulations. The speaker then glanced at the present methods of study, and compared with the past the high standard of medical education exacted by the Harvard Medical School and the facilities to that end, as given in the princely accommodations in the new medical building.

The audience was large, and the address, delivered in Holmes' inimitably happy style, was frequently interrupted with uproarious applause.

Dr. Francis Minot, on behalf of the donors, presented to the school a portrait of Dr. Holmes, painted by J. W. Alexander, to be placed in the college in remembrance of his invaluable services to Harvard University, to the medical profession, and to the community.

Ex-Mayor Samuel A. Green then presented to the school, on behalf of the donors, a bust of Dr. Henry J. Bigelow, executed by Launt Thompson, of New York. Dr. Green spoke of Dr. Bigelow's great contributions to the science of surgery, especially dwelling upon his researches on the hip joint and its dislocations, his wonderful operation of rapid lithotripsy, and his advocacy and advancement of the use of ether as an anæsthetic at the Massachusetts General Hospital after its discovery by Morton.

After this the audience proceeded to the new school-building, where prayer was offered by Rev. Dr. Peabody, and the building dedicated to the purposes of medical instruction.

Addresses were made by President Eliot in behalf of the Corporation; Henry Lee, Esq., in behalf of the donors, and Professor Henry W. Williams, in behalf of the medical faculty.

The building was then declared open to the inspection of the guests and was viewed with great satisfaction. Among the visitors were Sir William McCormac and Sir Lyon Playfair, Mr. Clinton T. Dent, of London; President D. C. Gilman, Johns Hopkins Hospital, Baltimore;

President Laws, University of Missouri, and President E. G. Robinson, Brown University, Colorado; Robert Murray, United State Army; Professors Osler, Campbell, and Howard, Montreal; Drs. Mullen, of Hamilton; Atkins, of Toronto, and Professor T. Sterry Hunt, of Montreal; Professor Carmalt, of Yale College; Drs. J. Marion Sims, Fordyce Barker, C. R. Agnew, J. C. Dalton, W. H. Draper, T. E. Satterthwaite, C. C. Lee, G. F. Shrady, of New York; Drs. Mears, Minis Hays, H. C. Wood, Tyson, and Woodbury, of Philadelphia; Drs. Wood, Gerrish, and Dana, of Portland; Twitchell, of Keene, N. H.; Gale, of Brattleboro, Vt.; Drs. Caswill, Ely, Miller, and Parsons, of Providence, and many others representing different parts of the country. In the evening a reception was tendered at Young's Hotel where a bountiful collation was served.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, October 18, 1883.

FORDYCE BARKER, M.D., LL.D., PRESIDENT, IN THE CHAIR.

ACTION ON THE PROPOSED AMENDMENTS TO THE CONSTITUTION AND BY-LAWS.

AFTER the reading of the minutes of the last stated meeting and the report of the librarian, the Academy went into Committee of the Whole, with Dr. Ellsworth Eliot in the chair.

DR. AUSTIN FLINT, JR., said he did not desire to discuss the proposed amendments, but wished to say a few words in explanation. He did not pretend to represent any one or anybody, but simply was the spokesman of a certain number of gentlemen who are deeply interested in the Academy, and who believe that it can be best preserved in its usefulness by maintaining its present Code of Ethics, and who are uncompromisingly opposed to these amendments, one and all. The one object of the amendments is to eliminate from the By-laws and Constitution of this Academy everything relating to medical ethics, and to reduce it to a purely scientific body. Dr. Flint further spoke of the effect which would be produced upon the Council by the adoption of the proposed amendments, and at the close of his remarks moved that the committee rise.

After some discussion as to whether or not the motion to rise was debatable, and in which the decision of the Chairman was sustained that it was not, the committee rose.

After further discussion as to whether the Committee of the Whole had yet reported, and in which the decision of the President was sustained, the Secretary of the Committee of the Whole at the stated meeting held October 4th, Dr. W. M. Carpenter, was requested to report, who then read the resolution offered by the President and adopted by that committee.

The resolution was that the Committee of the Whole regarded it as advisable to adopt the proposed amendments to the Constitution and By-laws.

DR. A. FLINT, JR., moved that the report be laid upon the table.

On this motion the ayes and nays were called.

After some discussion as to which should be used in calling the names of the voters, the register of the evening or the roll of the Academy, it was decided by a vote of 88 ayes to 84 nays that the register should be used. The vote on the motion to lay upon the table was then defeated by a vote of 115 nays to 96 ayes.

DR. A. L. LOOMIS then moved that when the vote on the amendments is taken it be by ballot. Carried.

Dr. Loomis then moved that the Academy proceed to ballot on the proposed amendments and by-laws.

DR. A. FLINT, SR., moved as an amendment that the proposed amendments to the Constitution and By-laws be indefinitely postponed.

The ayes and nays were then called for and the result was: Ayes, 94; nays, 117.

DR. LOOMIS then renewed his motion that the Academy proceed to ballot on the proposed amendments. Carried.

THE PRESIDENT appointed as tellers Drs. H. D. Nicol and Daniel Lewis, with the Assistant Secretary, Dr. A. M. Jacobus.

The result of the ballot was 121 votes for and 92 against. The amendments were declared lost, as they required a three-fourths vote to adopt them.

THE PRESIDENT then said: I beg the indulgence of the Academy for a few moments only. Duty and honor demand that every member of an organization like this Academy of Medicine, with its high scientific aims and its joint stock property necessary to make those aims attainable, should cheerfully bow to the will of the majority. No one can doubt that it was with pain and regret that I announced the vote of failure to adopt the amendments which I regarded as most important for the future of the Academy. Having given my reasons for this belief in a letter addressed to every Fellow, and having at the last meeting still further explained my views, and having failed to convince a sufficient number to secure their adoption, I bow with submission to the decision. No one can assert that I have sought to secure my end by personal influence or personal solicitation. I have felt that this matter should be left to the intelligence and judgment of such a class of men as constitute this Academy, unbiased by passion or partisan feeling. I am well aware that it demands a higher tone of principle, and a more noble magnanimity, to cheerfully acquiesce in the will of a minority, but I now earnestly beg of all to forget, so far as this Academy is concerned, all past controversies, many of which, I am convinced, are not so much differences as to principles, as differences in regard to details—and that all should unite in earnest work for this Academy in its high endeavors to advance medical science, to support and increase this important library, for which so much has been done in the past by most liberal benefactors, and to keep up the journal and circulating department. For my own part, I can only promise for the future what I have sought to give in the past, my best efforts in this direction, not only while I have the honor to hold my present position, but ever after. [Great applause.]

DR. A. L. LOOMIS read the preamble and resolutions passed at the stated meeting of the Academy last spring, by which the Committee on Admissions was instructed not to report for active fellowship the name of any candidate who could not sign the By-laws of the Academy containing the Code of Ethics of the American Medical Association, and then moved that they be *rescinded*. He urgently appealed to the Academy to support his motion in the interests of harmony.

DR. E. C. HARWOOD rose to a question of privilege and submitted in writing an explanation of his vote on the resolutions at the time of their adoption.

DR. A. FLINT, JR., raised the point that the motion was out of order, because when the resolutions were adopted their reconsideration was postponed indefinitely.

THE PRESIDENT ruled that the motion was in order, on the ground that rescinding and reconsidering are entirely different.

DR. FLINT appealed from the decision of the chair.

The chair was sustained.

DRS. ROOSA and AGNEW supported the motion.

DR. LEON opposed it, and moved to adjourn, but his motion was lost.

DR. PIFFARD moved the previous question. Carried.

The motion to rescind and abolish the preamble and resolutions adopted at the meeting in April, 1883, was carried. [Great applause.]

The Academy then adjourned.

Reviews and Notices.

ANLEITUNG ZUR TECHNIK DER ANTISEPTISCHEN WUND-BEHANDLUNG UND DES DAUERVERBANDES. VON DR. MED. G. NEUBER, Privatdocent an der Universität Kiel. Kiel: Verlag von Lipsius und Tischer. 1883. A GUIDE TO THE TECHNIQUE OF THE ANTISEPTIC TREATMENT OF WOUNDS AND THE PERMANENT DRESSING. By DR. G. NEUBER, Privatdocent in the University of Kiel.

SINCE the adoption of the antiseptic method in Professor Esmarch's clinic at Kiel, several modifications have been introduced and carried out with marked success by Dr. Neuber. The most remarkable of these is the method of permanent dressings ("Dauerverband"), by which a large proportion of operation-wounds have been completely healed under one bandage or dressing. Details of this method and its results have been from time to time communicated through papers by Dr. Neuber in the *Archiv für Klin. Chirurgie*, which have been frequently quoted. The present volume of about one hundred pages, with numerous illustrations, is intended to be a complete guide to the practice of the Kiel clinic, together with a statistical record of its results. But it is more than this. It is a thoroughly good treatise on the subject of wound-treatment, and as such, and quite independently of its relation to the author's own methods, we recommend it warmly to the reader, and hope that a translation may place American surgeons in a position to show such creditable statistics as are exhibited in its pages.

INSANITY: ITS CLASSIFICATION, DIAGNOSIS, AND TREATMENT. A Manual for Students and Practitioners of Medicine. By E. C. SPITZKA, M.D., Professor of Medical Jurisprudence and of the Anatomy and Physiology of the Nervous System at the New York Post-Graduate School of Medicine; President of the New York Neurological Society; formerly Physician to the Department of Nervous Diseases of the Metropolitan Throat Hospital, and of the North-Eastern Dispensary. 8vo, pp. 415. New York: Bermingham & Co. 1883.

A PERUSAL of this work can hardly fail to leave the impression that there are at least two factors in its etiology. To speak in a psychiatric, we will not say Pickwickian, sense, these might be designated as the psychical and somatic. The psychical factor may be perceived in the natural desire of the author, as explained in the preface, to embody his individual views on certain phases of his subject, which have previously appeared in isolated communications to the medical press, in "the first systematic treatise on insanity published on this side of the Atlantic since the days of the immortal Rush" (and which, by the way, is dedicated on the previous page as an "humble tribute").

The somatic factor—to force the metaphor a little—crops out in the excess of spleen manifested in the author's numerous and uncalled-for uncomplimentary allusions to the attainments and qualifications of certain alienists, whose expert testimony in a recent *cause célèbre*, with which the profession are too familiar, happened to conflict with his criterion. It is with considerable hesitation that we make any reference to a subject, which is at best an unpleasant one, but Dr. Spitzka's policy in this particular is far too pointedly expressed to admit of any other inference than that this publication is intended, not merely as a vindication of his own position, but also to accomplish the alienistic annihilation of those gentlemen whose views on insanity in general, and on Guiteau in particular, have been the reverse of his own. It would have been more considerate, not to say logical, in Dr. Spitzka, after having observed "the failure" of his brother experts "to properly co-ordinate"

upon the witness stand "their impressions" of the murderer of Garfield "as the basis of logical conclusions and actions," to simply prove to them that they were the unfortunate subjects of "the so-called chronic delusional insanity" with marked symptoms of "moral perversion," instead of emulating "the Fourteenth Street assassin" by running a muck among them armed with a venomous pen. He should not only have remembered that "no delusion was ever cured by ridicule," but should have also taken into account the fact that, in the absence of any "scientific treatise on insanity on this side of the Atlantic," the "special points" on which he based his diagnosis might yet have been "comparatively new" and strange to them. We believe some such classification as we have suggested would have possessed quite as much intrinsic weight with intelligent "students and practitioners," as his own amiable division of the alienists who failed to agree with him on one particular case into "a combination of medical politicians, gynecologists, and laymen" (p. 357). Dr. Spitzka, however, having proved to his own satisfaction that the testimony of these individuals was "in harmony with the age, circumstances, and surroundings" of such a "combination," and thus depriving them of even the pitiable plea of insanity, proceeds to "knock them out" with a display of vigor and vivacity more suggestive of a follower of Mr. John L. Sullivan than "the immortal Rush." Vituperation is poor logic, and it certainly is unfortunate that the "first systematic treatise, etc., etc.," should savor so strongly of the campaign document. Extreme assertions, especially those of a personal character, are always to be taken *cum grano salis*. So, when such assertions are coupled in a scientific treatise with the expression of views which, in the present state of American psychiatry, the author admits to be extreme, he should not complain should the profession show a tendency to treat them with the same seasoning.

It has been far from a pleasant or congenial task to criticise in this manner Dr. Spitzka's otherwise scholarly work. That he has allowed personal animus to enter into a scientific discussion is the glaring defect of the book. It is forced upon the reader in a way which calls for comment. We think the profession at large will agree with us that such comment should be emphatic and condemnatory. That our remarks have been neither "finical or hypercritical," we submit the single fact, which the reader will scarcely be able to convince himself is a coincidence, viz., that, whereas every expert on the Guiteau trial, with but one exception, is industriously called upon in these pages to figure in a rôle analogous to that of the "terrible example" in a temperance lecture, the single witness whose testimony supported Dr. Spitzka receives the most effusive and flattering recognition. A glance at the index shows that reference to this authority is made no less than ten times, while Esquirol, Krafft-Ebing, Meynert, Maudsley, Bucknill, Take, and other minor lights, are either dismissed with the most casual mention or "damned by faint praise." The inference is obvious.

The strictly scientific part of Dr. Spitzka's book is deserving of considerable praise. The accomplished author displays throughout a masterly grasp of his intricate subject and a familiarity with its bibliography which is in the highest degree commendable. The volume has been issued in fairly neat form, though the few woodcuts, with one or two exceptions, are poor. The chief fault discernible in the author's style is the rather common one of an undue preference for forced derivatives, which is plainly to be attributed to an attempt to secure thoroughness and exactness of expression, but which often has the effect of causing his elaborate sentences to appear involved and unnatural, necessitating somewhat the same strain upon the attention which one experiences in reading a too literal translation of one of the ancient classics. It is, however, interesting to learn that "verbigeration" in cultivated parietic dements "in less edu-

cated ones" is replaced by a "*word diarrhæa!*" (p. 210). The oversight which makes "*Prosencephalon*" a Latin word (p. 101) would be trivial did it not occur in a discussion on derivation. Aside from the author's tendency to sacrifice simplicity to detail, the presentation of his arguments is direct and decided, his illustrations usually apt and well put, and his exposition of the most important points forcible, though occasionally dogmatic.

Dr. Spitzka's elaborate definition of insanity is avowedly altered to meet the exigencies of medical jurisprudence, although we question whether an American jury which is not chosen from the members of the Concord School of Philosophy would derive a much clearer idea of insanity from it than from Shepard's playful *dictum* about the "neurine batteries of the brain." We might also venture to question the soundness of the syllogism that, whereas "mental pathology has made more rapid progress in Germany, Italy, and France, where little stress is laid on such definitions, than in England or America," and whereas "an English author on lunacy" has offered a definition with the object of "puzzling the lawyers," that *therefore* in Anglo-Saxon countries the "chief need for the definition is a medico-legal one."

Dr. Spitzka's definition is neither much worse nor much better than many others with which the profession is familiar. While it may certainly be true that "the inability to correctly register experiences and impressions in sufficient number to serve as guide for rational conduct is an essential feature of idiocy or imbecility; and while it may also be true that "the failure to co-ordinate impressions as the basis of logical conclusions is the characteristic feature of insanities manifested by delusive opinions, insane projects, and imperative conceptions"—and while the words "in harmony with the individual's age, circumstances, and surroundings" are added as qualifications, with propriety, nevertheless, until we have some mathematical standard by which to prove that any given impression is registered correctly, that any given conclusion is logical, and that any given action is "in harmony with the individual's environment, such a definition will be worthless in a court of law. Any lawyer could make it exclude the insane, and include the sane, at will. He certainly has not improved upon Dr. Bucknill's classical definition of insanity as "a condition of the mind in which a false action of conception or judgment, a defective power of the will, or an uncontrollable violence of the emotions and instincts, have separately or conjointly been produced by disease," which is shorter and clearer than his own, and fully as accurate.

In our opinion, Dr. Spitzka underrates the importance of the psychological treatment of his subject throughout. Such a treatment is assuredly more truly scientific, and can be made as completely practical as one more distinctively clinical or pathological. It may be that the enthusiasm with which he has developed the somatic elements of insanity has blinded him in a measure to its psychical bearings. The chapters on "The Physical Indications of Acquired Insanity," "Somatic Signs of Insanity Indicating the Existence of a Constitutional Taint of, or a Predisposition to Insanity," and "The Morbid Anatomy of Insanity," are by far the most readable and suggestive, as well as the best sustained in the book. But this very fact makes the work an uneven one. Aside from these, his discussion of monomania and parietic dementia will probably prove most interesting to the student of psychiatry. He has evidently taken a great deal of pains to give a perfect "classification of insanity." In this he has shown more than his usual skill and adroitness, and the classification is certainly a sound one from his point of view.

ANNUAL REPORT OF THE BOARD OF HEALTH OF THE STATE OF LOUISIANA TO THE GENERAL ASSEMBLY, FOR THE YEAR 1882. Baton Rouge: Leon Jastremski, State Printer. 1883.

THIS voluminous report, consisting of over six hundred pages of printed matter, besides several intercalated sta-

tistical tables, embraces a period of eighteen months, from January 1, 1882, to July 1, 1883. The volume contains a detailed report of the quarantine and sanitary operations of the board during this time, an account of the commercial growth of the State under the successive dominations of France, Spain, and the United States; peculiarities in the political and medical history of Louisiana, the etiology of phthisis, the climate of Rio Janeiro, a letter to his Excellency the President of the United States, treatises on yellow fever and malarial fevers, illustrated with eleven highly colored lithographic plates, and a varied assortment of other interesting material. The Louisiana State Board of Health has done some hard work, and some very necessary and valuable work, but if it is no more economical in other matters than it is in the use of paper and printer's ink, we fear it must be a very expensive institution.

PRACTICAL LESSONS IN ELEMENTARY PHYSIOLOGY AND PHYSIOLOGICAL ANATOMY for Schools and Science Classes. By D. M'ALPINE, F.C.S. Twelve Plates. London: Bailliere, Tindall & Cox. 1883.

THE book before us is of the size of an atlas, and contains a folded leaf with colored lithographs showing the vertical section of a frozen child, also separate lithographs of the different viscera. Besides this, there are two full-page lithographs showing sections of the rabbit, and numerous other plates showing different tissues and organs.

The author's object is to present a work which will be practical, realistic, and attractive to science students. In selecting the rabbit as the animal whose anatomy is to be studied, the author has made a wise device, for it is much more easily handled than the cat or dog.

WHAT TO DO FIRST IN ACCIDENTS AND EMERGENCIES. By CHARLES W. DULLES, M.D. Second edition, revised and enlarged. With new illustrations. Philadelphia: P. Blakiston Son & Co. 1883.

THIS little manual is intended more especially for use in the absence of the physician. The immediate treatment both of surgical and other injuries and accidents is presented in a plain and very acceptable manner, and will undoubtedly prove a useful guide in many emergencies. Among the various cases dealt with are: Drowning, fits, effects of heat and of cold, sprains, fractures, wounds, hemorrhages, etc., etc., together with various domestic emergencies.

POISONING BY SALICYLATE OF SODA.—Dr. Pineau writes in *L'Union Médicale*, of July 5, 1883, of a young man, suffering from typho-malarial fever, who took by mistake two and a half drachms of salicylate of soda. Nothing unusual was noticed for over two hours, when the patient was suddenly seized with extreme weakness, amblyopia, and tinnitus aurium. The entire surface of the body became blue and the extremities were cold. Finally such a profuse perspiration broke out that the mattress was soaked, and the patient was enveloped in steam as if in a vapor-bath. This condition lasted for about three hours. When seen several hours later, the patient was pale and still covered with a cool sweat. He had not urinated for about twenty-four hours, but passed at this time nearly a pint of strongly acid urine, not albuminous, and containing 26.4 grammes of urea per litre. The patient recovered without special treatment. The fever from which he was suffering subsided and convalescence became at once established. The reporter does not state the mental condition of the patient, except to say that he did not at any time lose consciousness entirely.

LACTIC ACID IN DIPHTHERIA.—Dr. J. P. Lytle reports favorable results with a spray of lactic acid in diphtheria. He says that it rarely fails to dissolve the membrane in two or three applications. The solution used was of the strength of lactic acid, grt. xxx.; aquæ, ʒi.

Correspondence.

RANDOM NOTES AND OBSERVATIONS OF A
TRIP THROUGH THE GREAT NORTHWEST.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR: Having participated in the opening excursion of the Northern Pacific Railroad, your correspondent had rather exceptional opportunities to observe many of the distinctive features of the far West, together with its peculiarities of life and manners. It may interest some of your readers to be made acquainted with the impressions, more particularly from a medical point of view, which the wide West makes on what is commonly there called an "Eastern tenderfoot." Now, "tenderfoot" is not to be construed as the Western equivalent of that much evolved and more abused specimen of mankind, familiarly styled "dude." For even the Montana cowboy recognizes the latter. Not that he has ever seen the true prototype of a class that was erstwhile so numerous among us. But he is convinced that a person caught in the act of wearing a white linen collar, and who looks as though he might have recently shaved or washed his face, must be a dude, true and proper. And, moreover, since the typical Westerner freely, and often quite forcibly, expresses his convictions, the term "dude" is at present perhaps oftener employed west of the Mississippi than east of it. Please pardon this explanatory digression, but it really seemed essential to point out that the tenderfoot need not necessarily be a dude, and *vice versa*.

Your correspondent spent one week in Chicago, and endeavored to ascertain the status of the medical profession there. Considering the amount of talent in its ranks, it stands much lower than it should. The principal blame for this unfortunate circumstance must attach to the physicians themselves. The Chicago doctors are under-paid, and, therefore, under-estimated.

The phenomenal growth and commercial prosperity of this great Western metropolis excite the wonder and admiration of all visitors, native as well as foreign. This unparalleled rise is without the slightest exaggeration one of the wonders of the world. But the Chicago doctors lag behind, pecuniarily and in popular esteem. And why? Simply because as a class they charge too little for their services. The Chicago of to-day is no longer a merely rising city, whose inhabitants fondly dream of future glory. It is a great living actuality, with an assured future of still greater accomplishment. Why, then, have the Chicago doctors retained the "small-city fee?" In commercial capitals the principle of valuation is the predominant one. Price determines worthlessness as well as worth. Whatever is excellent commands a high figure. Hence the people argue that cheap doctors must be poor doctors. It would be difficult to convince the average citizen of the fallaciousness of such reasoning. The remedy for this evil is self-evident. Let the doctors charge more. The old established physicians must lead this reform movement. They will lose patients at first, but they will gain in prestige, and their incomes will not suffer. In the end they will have elevated the profession as a whole, while they will have benefited themselves as individuals.

This is not idle talk. It is the earnest advice of one who would fain see his chosen profession lifted above, or at least to the same level with other callings. For such eminence is but the just reward for a life of ceaseless toil and self-sacrifice, and for the unhesitating assumption of graver responsibilities than any other profession entails. And in this connection the writer would be pardoned for humbly suggesting to the profession at large the advisability of inculcating "high-fee" principles, as essential to the proper standing of the doctor in the community. Sordid motives should ever be foreign to our profession. But let us recognize the actual commercial value of our services, without sham hesitancy, without

the assumption of false modesty, without maudlin sentimentality. For as yet ours is a young country, where commercial values rule the day. In the ideal world that is to replace the present imperfect one, the doctor may well make fifty cent visits, and take the balance out in sentiment; but at present sentiment will not pass current in buying bread. And God knows the doctor needs bread, as much, if not more so than other mortals. And now let there be no further digression, but a broaching of more novel themes.

Concerning the evils of hospital management, and the intrigues of rival medical schools, it is quite unnecessary to write. Pretty much the same flavor attaches to these matters in Chicago as in New York. The less one dwells on such sore spots of the body medical the better. A few words about a new and highly deserving charity that has been quite recently inaugurated in Chicago. It is called the Lakeside Sanitarium. It has for its object the treatment of infantile diarrhoeal diseases occurring during the warm weather. A commodious pavilion has been erected fronting the lake. Here the poor mothers take their suffering babies, the latter remaining all day. Hammocks, a kitchen, bathing facilities, the necessary drugs and restoratives have been provided, and a medical staff makes several daily visits. Dr. Randolph, formerly of the St. Francis Hospital, of New York, is one of the physicians in charge. He kindly explained the system to your correspondent, and pointed out the gratifying success that had already attended the life-saving efforts of this young institution. The immediately rallying effects of the pure lake breezes are a matter of constant surprise to all who witness their action upon the babes removed from crowded tenements. A rather serious drawback, however, would appear to be the present impossibility of allowing the little ones to remain in the sanitarium over night. But of course, with the growth of the institution, this defect will be remedied.

In taking leave of this city, it may not be amiss to repeat a story, that seems to your correspondent quite typical of Chicago and its rapid growth. A patriotic citizen having returned from a prolonged journey abroad, meets an old friend in the street, when the following brief colloquy ensues: "Well, old boy, I'm glad to see you back, do you think we've changed any while you were away?" "Changed," replies the former, "why don't you know we have lied about Chicago, and lied about her, and continued to lie about her. And yet to-day she is away ahead of all our lies!" Mayor Carter Harrison probably knows of this story.

About Minnesota it would be easy to say, with perfect justice, many pleasant things. In the first place, the Eastern traveller cannot fail to be agreeably affected by the exhilarating effects of its dry, crisp air. There is something so very unmalarious about it that one feels inclined to doubt whether the Minnesota doctor ever prescribes quinine. Almost the entire State is elevated from one thousand to two thousand feet above sea-level. Hence, its climate shows those peculiarities that are more or less characteristic of the entire Northwestern region—that is to say, there is an almost daily change from hot to cold, with a thermometrical range above 50° in spring and winter, and a variation of about 40° for the summer. Nevertheless, neither the almost tropical heat, nor the extreme cold ever become so oppressive and unbearable as we are accustomed to find them in New York.

Chronic pulmonary diseases appear to be rare in Minnesota; and indeed its salubrious climate would lend itself readily to the establishment of sanitary resorts for those afflicted with such maladies.

One circumstance strikes the traveller as quite peculiar in Minnesota, and that is the conspicuous absence of very old persons. Indeed, to a greater or less extent this applies to the entire region traversed by your correspondent. Leading physicians resident in the various towns and villages along the road are ready to admit this,

as a feature of the new life in their rapidly growing country.

The explanation they offer is based not on one, but on several facts, all operative in the same direction, viz., that of curtailing man's natural term of existence. Most potent among these various factors is the high tension of all human activity out there. Working with half-power is a thing unknown. All faculties are enlisted, all energies constantly strained to accomplish the chosen task of life. What wonder, then, that nature's stock of reserve force is early exhausted; and a sudden, complete collapse, as of the one-hoss shay, is the rule, not the exception. Death seems merciful, and does not linger in the lap of long and painful illness, as is so frequently the case with us. It takes the system by surprise, as it were; there is a short, sharp struggle, with a quick decision either one way or the other. Slight ailments would appear to be both less frequent and less attended to than in the East. Chronic affections are likewise fewer, in proportion, than elsewhere. Of course, all this is to be taken in a broad, general way, and not as a rule without exceptions.

One derives the impression, from the above, that the people there have no time to dally with disease. They are constantly in a hurry, even when sick. Evidently, they have not yet reached that point of civilization which allows them to "make haste slowly."

Respectfully yours,

EDMUND C. WENDT.

136 WEST THIRTY-FOURTH STREET,
New York, October 10, 1883.

(To be continued.)

THE THERAPEUTIC VALUE OF THE COLORADO CLIMATE.

TO THE EDITOR OF THE MEDICAL RECORD.

I HAVE been a reader of THE RECORD for four years, and do not remember ever to have seen a line in that journal in reference to Manitou or the State of Colorado as a health resort. I have observed also that among the numerous invalids who come to this section from nearly all parts of the world, it is rare to see one who hails from New York. The writer practised medicine in Brooklyn for three years, and I do not remember any mention of this place by the physicians of that city during that time. It has occurred to me, therefore, to endeavor to call the attention of New York physicians to the merits of Colorado as a resort for those afflicted with lung diseases. For this purpose I prefer to speak of my own experience and immediate surroundings, rather than make use of the various statistics collected by others.

The population of Colorado is largely made up of persons who came here originally on account of some lung disease, and have either recovered or found relief.

From the careful observation of such cases as have come under my care or notice, I think the following statements may be formulated as true: Spasmodic asthma is invariably and immediately relieved by a residence in Colorado. Asthma, accompanied by emphysema, bronchitis, or consumption, is relieved only in proportion as the catarrhal state of the air-passages is improved. Hay fever is not relieved. Nasal catarrh is usually much worse for a few weeks, when decided amelioration or a cure follows. The effect of this climate upon consumption is peculiar. The barometer stands at 22 or 23 inches; consequently the rarity of the atmosphere is great, and acts practically like a cupping-glass upon the blood-vessels. The altitude of Manitou is one and a quarter mile above the sea, and, as would be expected, an extraordinary expansion of the lungs is required to supply oxygen to the blood. Much of the reserve space of the lungs is called into use; diseased tissues are forcibly torn open; a passive catarrh of the lungs is converted into an active inflammation; slight or profuse pulmonary hemorrhages often occur; and what was be-

fore a slight cough, with moderate expectoration, becomes frequently a violent, almost incessant, cough, with profuse expectoration. With this there is usually more or less elevation of temperature. In a period of time varying from one month to one year, the fever disappears, the cough diminishes, and the expectoration becomes more scanty, and from this time on, in favorable cases, the patient progresses toward a complete recovery. As far as I am able to judge, no cavities result from this violent disturbance of the lung tissues.

I have sketched briefly a typical case, as observed in many instances. As would be inferred, this would represent a patient in the earlier stage of catarrhal pneumonia, in whose lungs no serious damage had occurred before coming here, and whose vital forces were still good.

Where the lungs are very seriously affected, and the vital forces are much impaired, the process of healing which I have outlined, viz., the conversion of a passive, lingering catarrh into an active inflammation, is not well borne, and is apt to end fatally much sooner than in a mild southern climate.

As far as my observation has gone, every case of consumption accompanied by early hemorrhages has been cured in this climate, if the patient has come here within a few months of the invasion of the disease. The time required for the symptoms to cease is from three months to two years. In other cases, unaccompanied by hemorrhage, resorting here shortly after the invasion of the disease, the majority have been entirely relieved of all symptoms. A certain proportion have succumbed to wasting hectic fever; others have fallen into a chronic condition, where progress in neither direction seems to have been made for ten and even twenty years.

The climate of Colorado is extremely dry. It never rains from the middle of September until the middle of April—seven months. Three years ago there was no rain for eleven months. In the summer showers occur nearly every day at about three o'clock in the afternoon. Snow-falls come in the winter months. They seldom exceed two inches in depth, and lie upon the ground not longer than twenty-four hours. In 1881 there were two such flights of snow in Manitou; in 1882, three. During the winter the days are warm. An overcoat is not required. At night it is always cold, both in summer and winter.

Manitou is located at the foot of Pike's Peak. The scenery is such as to attract twenty thousand visitors annually. There are here nine mineral springs. Three are chalybeate; the remainder closely resemble the Apollinaris in taste and properties. There are here frequent mails and telegraphic facilities, railroads, banks, churches, and much that reminds one of New England life, while law and order are as good as in any place in New York.

The cost of living is from \$40 to \$100 per month. I add these details, as they are the subject of frequent inquiry by letter.

I could readily add many pages of notes of cases which have come under my observation, but they are tedious at best, and seldom read. It is of importance to say, however, that experience has abundantly demonstrated the fact that persons who have been relieved of all their symptoms here are extremely liable to a relapse if they return to the place where the disease was originally contracted.

FREDERICK FULLER, M.D.

MANITOU, COLORADO.

PERSISTENT HICCUGH CURED BY SUBCUTANEOUS INJECTIONS OF Pilocarpin.—Dr. Ruhdorfer, of Götzendorf, relates the history of a girl nineteen years of age who, for three months, suffered from an obstinate hiccough. All kinds of sedatives were employed in vain. Subcutaneous injections of pilocarpin, gr. ss. in ℥ xv. of water, finally gave relief. Stadler has reported a similar case cured by the same means.

THE ABORTION OF TYPHOID FEVER.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: The medical profession is skeptical as to the possibility of aborting typhoid fever. The editor of the *Medical Age* says: "We have given our opinion of the man who claims to abort typhoid fever, and while we may now regret the somewhat inelegant language in which it was couched, we shall not modify it until such evidence is brought to bear against it as will stand the test of science." Now, if Professor Busch can cure sarcomatous tumors with so simple a remedy as mustard and black soap, we need not despair that a scientific remedy to abort typhoid fever will be discovered. In my experience I was never able to accomplish that much-desired feat until in the epidemic of last year, but invariably stood a helpless spectator, witnessing one case after another attacked in the same family. That year I was attending a case in the third week, when two other members were complaining of the initial symptoms, and I gave them the following: Tinct. iodine, gtt x., every six hours; Fowler's solution, tinct. baptisia, āā gtt. v., every six hours, alternated with the iodine, so the doses came every three hours. In addition to the above, if malarial action was present, gave quinine in three-grain doses through the night. The result was abortion in all cases in the prodromic stage, and in a large per cent. of cases in the early stage of the fever before serious lesions of the mucous surfaces had occurred. Was that treatment scientific? The action of iodine and arsenic as bactericides are well known, but baptisia, being more restricted in use to the eclectic school, is not so generally appreciated. It is the vegetable analogue of the other two remedies and principally used because of its eminent antiseptic virtues. I procured the homœopathic mother tincture as the most reliable preparation. After learning the abortive effect of the above treatment I adopted it in a few advanced cases with benefit. The bronchitis improved and in one case the temperature fell two degrees by the next day.

J. M. WARD, M.D.

CORNELIA, MO.

[We print the above not so much for its real value as to show how entirely unconscious of the nature of the problem (which he thinks he has solved) our esteemed correspondent is. He evidently belongs to the "impressionist school" of which we have before written. It is one thing to believe in a remedy, it is quite another to demonstrate its efficacy. In order to do the latter, evidence must be diligently collected and presented. The most careful records of the alleged aborted cases should be made, otherwise the skeptical world will say that they were not typhoid cases at all, but that the patients were, perhaps, a little bilious.—ED.]

THE CONDEMNATION OF VESALIUS.—*À propos* of a recent painting representing Vesalius starting back affrighted at discovering signs of life in a man whom he supposed dead, and whose thorax he had just opened, M. Bouchut writes in the *Paris Médical* that the subject of the picture is historically incorrect. The story is that upon opening the chest a movement of the heart was detected, which was taken as proof that the subject was yet alive. For this Vesalius was tried before the Inquisition, and condemned to death, but at the urgent solicitation of Philip II. this sentence was commuted to a pilgrimage to the Holy Land. A Spaniard, named Morejon, has shown, however, that no such thing ever occurred. Vesalius was never tried before the Inquisition, and consequently never condemned. His pilgrimage to Jerusalem was made because of ill health, and from pious motives, and it was only with great difficulty that he could obtain from the king, whose physician he was, permission to undertake this journey.

Obituary.

FREDERICK D. LENTE, M.D.,

COLD SPRING, N. Y.

DR. FREDERICK D. LENTE, an eminent physician and surgeon, died at Cold Spring, Putnam County, N. Y., in the sixtieth year of his age, on the 13th inst., of cerebro-spinal meningitis. Dr. Lente was born at Newbern, N. C., in 1823, and was a graduate of both the University of that State and of the University Medical College of New York. After leaving the latter college he studied for a time under Dr. Alfred C. Post, and was afterward, under Dr. Valentine Mott, for two years, on the house-staff of the old New York Hospital, which at that time had attained its greatest reputation. In 1851 he was appointed surgeon of the West Point Foundry, at Cold Spring, and filled that position until 1870, when he came to this city, and was almost immediately appointed to the Chair of Gynecology and Diseases of Children at the University Medical College. He filled other positions of honor and influence in this city, but in 1871 he was compelled to give them up on account of threatened failure of his health. He returned to Cold Spring, and, resuming his former position there, remained until 1875, when he once more left it and entered upon the practice of his profession at Palatka, Fla., during the winter months, and at Saratoga Springs in the summer. Dr. Lente was one of the founders of the American Academy of Medicine and its first President, and at the time of his death he was a member of the Neurological, the Pathological, and the New York and Dutchess County Medical Societies, the American Public Health Association, the Board of Managers of the Hudson River State Hospital, corresponding member of the New York Medico-Legal Society, and honorary member of the North Carolina Medical Society. Dr. Lente had an extensive acquaintance and reputation through the Northern and Southern States as a general practitioner and as a surgeon. He was not only skilful and successful here, but he had an original and observant mind. His numerous contributions to medical literature were always valuable and were widely noticed. His work was characterized by great thoroughness and exactness. Personally, Dr. Lente was very popular among all who knew him, and was warmly esteemed by an unusually large circle of friends.

Navy News.

Official List of Changes in the Medical Corps of the Navy, for the week ending October 13, 1883.

HILAND, THOMAS, Surgeon. Granted leave of absence for one year, with permission to leave the United States.

SIMON, WILLIAM J., Surgeon, and CRAWFORD, M. H., Passed Assistant-Surgeon. Ordered to report on November 1st for duty on board the U. S. S. Trenton.

A CASE OF CONGENITAL HYDROCEPHALUS, WITH IMMENSE CRANIAL DEVELOPMENT.—Dr. C. I. CONOVER, of Charleston Four Corners, N. Y., relates the history of a patient, Mrs. D—, whom he had been called to attend in confinement. He found a breech presentation. After a time, no progress being made, and the child being found to be dead, the mother was anesthetized, and the base of the infant's skull punctured. About three pints of hydrocephalic fluid flowed away. The child was finally expelled. All parts of the child were normal except the head, which measured, we are told, twenty-three inches, the normal measurement being thirteen. Dr. Conover has preserved the head in a bottle to convince the incredulous.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending October 16, 1883 :

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
<i>Cases.</i>

<i>Deaths.</i>								
October 9, 1883.....	0	25	2	6	5	14	0	0
October 16, 1883.....	0	19	5	3	4	13	0	0

STATE VETERINARY SOCIETIES have recently been organized in Illinois, Michigan, Wisconsin, Ohio, Indiana, Iowa, and Pennsylvania. It is proposed to organize one in this State.

ASTHMA CURED BY GALVANIZATION OF THE NECK.—Dr. Peter Eade reports a case of essential asthma of a year's standing cured by galvanizing the neck. The current was applied daily for ten days.—*British Medical Journal*.

THE STEREOSCOPE IN THE STUDY OF ANATOMY.—Mr. S. F. Elliman has been making experiments with reference to the use of the stereoscope in illustrating the anatomy of the domesticated animals. He exhibited his pictures before the Veterinary Society of the Gironde. The following comments are quoted by the *Journal of Comparative Medicine*: "Applied to anatomical subjects the stereoscope causes to stand out in a manner not less remarkable the complicated parts; it prolongs the view to the bottom of the great nervous cavities; it detaches the muscle from the bone which it covers; in short, it recalls to the student, as to the surgeon, the anatomical peculiarities belonging to each region of the body. One might say, to a certain point, that, thanks to this instrument, it is possible to study anatomy in one's own room; that is to say, without operating on the dead body, by the aid of which the conformation of the organs is generally studied. The application of the stereoscope to anatomical studies is, then, a very happy idea, and of which one must allow the Bordeaux Exhibition has given the first example."

IN A CASE OF HEMORRHAGE FROM THE INTERCOSTAL ARTERY, from homicidal stabbing, I arrested the flow immediately by making pressure within the pleural cavity, directly on the vessel, by introducing into the wound the handle of a door-key. The key was then turned transversely, so as to make direct pressure, and maintained in that position for some hours, until there was no more tendency to hemorrhage. The same mechanical action might be effected by the similar use of the handle of an ordinary gimlet.—DR. LEVIS, Philadelphia.

HOW TO HANG.—The death of Marwood, the London hangman, has revived a melancholy interest in the best methods of strangling people. An English journal describes a new invention in this particular line which is said to be remarkably effective. The inventor brought his machine to London and showed it to various persons there. A reporter who examined it writes: On near examination it was found that the rope was the ordinary half-inch white hemp, passed double through a brass clamp, forming a loop which could be adjusted to the exact thickness of the neck of the criminal. Immediately

before the clamp was fitted a brass crescent measuring nine inches from tip to tip and projecting three inches from the rope. This brass crescent is so adjusted as to lie on the shoulder of the condemned, while the double rope is looped on one side so as to allow a drop of from two to four feet. The principle of the invention is that the moment the criminal is swung off the crescent presses against the side of the head, while the rope pulls the neck sharply in the opposite direction, snapping the spinal column like a stick of sealing-wax, and occasioning instant death. "It cannot fail," said its inventor, as he lovingly fitted the hempen loop round the neck of one who was present at the interview, and screwed the clamp tight at the right distance. "It will hang you sideways, back or front, just as you like; it cannot fail; just drop off this table and it will be quite sufficient. No need of a long drop, no pulling men's heads off their shoulders; everything painless; the very invention that is wanted. The leverage gained by the three-inch projection of the brass crescent will snap any one's neck." "But might not the rope snap?" he was asked. "No, because its double; Marwood uses a five-eighth inch rope for a long drop; one-half inch double for a short drop will be more than is necessary. Jack Ketch always used the one-half inch. The thinner the rope the surer the job. You can hang a cat with a whiplash, but not with a half-inch rope." "How did you try your experiments?" "By making lay-figures of various weights, fixing a block of wood as a head on a stout pole, surrounded by wire springs to represent the vertebrae of the neck. I have tried it with many weights and many lengths of drop, and never found it to miss. In the cause of humanity and civilization I appeal to you to secure the adoption of this humane invention." The inventor, after disengaging the apparatus, then left for the Home Office, carrying with him his invention for presentation to the Home Secretary. His name is Scholefield, and he is now working at Palmer's ship-yard at Jarrow.

A VIAL FOR CARRYING SOLUTIONS FOR HYPODERMIC USE.—Dr. S. Mitchell, Jr., of Hornellsville, N. Y., sends the description of a vial which he has devised for carrying solutions for hypodermic use. The object is to provide a vial from which the solution can be readily drawn into the syringe. To accomplish this a tube perforated at the lower end is passed through the closed top of the vial to its bottom. The upper end of the tube is funnel-shaped. The needle is passed down into the tube and easily sucks the solution out of it.

DR. HOLMES' ADVICE TO A YOUNG PHYSICIAN.—Dr. Holmes, some years ago, wrote as follows to a young man who requested his advice about becoming a doctor: "My dear young friend—To be a physician the following requisites, if not absolutely necessary, are very desirable: First—A sound constitution. The wear and tear are very great, and cares, broken rest, irregular meals, and exposure of all kinds demand great stamina. Second—An unselfish nature. You must always think of your patient's welfare, not of your own comfort or habits. Third—You must be content to wait a long time before you establish a paying reputation. Fourth—Much of your work being distasteful, wearisome, wearing to the body, and almost fruitless to the mind, you must gradually harden yourself to the routine, and for this you ought to have an easy and accommodating temper. Fifth—You must be in constant familiarity with suffering of all kinds, which must either make your feelings tough, or keep you in distress. Medicine is very exacting. I don't believe much in literary doctors. I would not have one that was in the habit of scribbling verse, or stories, or anything of the kind. Yours, very truly, O. W. HOLMES."

DERIVATION OF THE WORD CHARLATAN.—In former times physicians received and treated their patients in their own (the physicians') houses, and seldom made visits outside, or if they did they went on foot. But there

came to Paris at one time a medical genius who knew how to care for himself better than he did to cure his patients. His name was Latan. He had a wagon (char) filled with medicines, and used to drive about through the streets seeking out patients and proclaiming the virtue of his remedies. He was the first travelling-doctor, and as he went through the streets the people used to say: "*Voilà le char de Latan.*" From this came the abbreviated form, charlatan, which came to be applied to all travelling quacks.—*Berliner Tagesblatt.*

The commonly accepted derivation of the word is from *circulatanus*, a corrupted form of *circulator*.

PATHOLOGICAL SPECIMENS FROM PREHISTORIC TIMES.—At the recent meeting of the French Association for the Advancement of Science, Dr. Prunières exhibited some bones found by him among the remains of the cave dwellers. There were specimens showing fractures united without deformity in the long bones, and one fracture of the atlas, with the fragments united to the axis in such a way as to reduce to one-third of its normal size the vertebral canal. There were also several vertebrae showing a spina bifida, the subject of which had lived to adult life in spite of the lesion.

CYSTIC TUMOR OF THE THIGH FOLLOWING RUPTURE OF THE CAPSULE IN MORBUS COXARIUS.—Dr. Alfred M. Leonard, of Camden, N. Y., reports a case under the above title. The patient, a young lady, at the age of thirteen fell from a tree striking squarely on the heel. She experienced some pain in the right knee and the limb continued to be weak. Three years later she fell while skating and struck upon the right hip. Inflammation of the joint set in. The patient was put in bed and extension applied. This was followed by the use of a long hip splint. After about three months symptoms of rupture of the capsule appeared. At the same time a small tumor made its appearance below, and behind the trochanter major, which increased rapidly in size, extending downward and laterally, soon necessitating the removal of the splint. It was accompanied by a complete cessation of all inflammatory symptoms; she has had no pain, or discomfort otherwise than that caused by the bulk and weight of the tumor, or any febrile symptoms that would indicate toxæmia. An operation was performed, and ninety-two ounces of thin yellowish fluid withdrawn, containing large quantities of cholesterol crystals, mucin, and epithelium. The sac was removed, adhesions broken, and the wound dressed antiseptically. The wound healed by first intention, except a small fistulous opening which continues to discharge a thin, whitish fluid. The patient walks with a limp, but without artificial support. The movements of the joint are perfect and the limb but little shortened.

A CASE OF CYANOSIS IN WHICH THE INTER-AURICULAR AND INTER-VENTRICULAR SEPTA WERE BOTH DEFICIENT.—Dr. Hattie A. Gallatin, of Cleveland, O., reports the case of a male infant, eight months old, who suffered from cyanosis and occasional fainting spells. The child lived to be two and a half years of age. It was tall and delicate, with a disproportionately large head. The face, arms, and upper part of the body were usually cedematous, the surface cold, the patient chilly. The antero-posterior diameter of the chest was increased, the area of cardiac dulness large. Various murmurs were heard at times, the most constant being a *presystolic rippling* sound. The cyanosis was not always present, but came on in paroxysms with accompanying dyspnoea and orthopnoea. The paroxysms, at first rare, gradually increased in frequency until death. The appetite was good. There was considerable diarrhoea. The autopsy revealed the following conditions: heart normal in position and very large; lungs normal, though somewhat compressed by the heart, and dark colored; pericardium greatly congested, and usual quantity of pericardial fluid; the heart was of the size of the

adult female heart, with right auricle of unusual size; aorta, pulmonary artery, pulmonary veins, and venæ cavæ normal in position. Right auricle found to be very greatly dilated, being capable of holding two fluidounces. The foramen ovale was open about three-fourths of an inch in diameter with lax margin. The annulus ovalis seemed entirely wanting. No trace of Eustachian valve. Openings of cavæ, the walls, appendix, and muscoli pectinati, all normal. The auriculo-ventricular opening was a little large. Right ventricle: capable of holding two fluidounces. Walls one-half inch thick. Columnæ carnæ, chordæ tendinæ, and tricuspid valve normal. On attempting to pass a probe from the ventricle through the pulmonary artery, to my surprise the other end appeared in the aorta. Closer examination showed the inter-ventricular septum to be deficient at its upper margin, so that the aorta and pulmonary artery both communicated freely with either ventricle, or with both; most freely, however, with the right. The opening was three-fourths of an inch in diameter, and at the upper margin of the inter-ventricular septum. The semilunar valves of aorta and pulmonary artery were perfect. Left auricle: capable of containing less than an ounce, while the right had a capacity of two ounces; otherwise normal. Left ventricle: capacity of one and a half ounce. No abnormality but the deficient septum. Cases of cyanosis in which the inter-auricular and inter-ventricular septa are both deficient are not of frequent occurrence. Smith, in his table of one hundred and sixty-four cases, does not mention any of this variety, unless he includes them under cases of "one auricle and one ventricle," which seems improbable, as both septa were present though imperfect. Other authors mention this condition, but he has not been able to find any reliable statistics concerning it. Nor has he found any satisfactory cause assigned for the almost complete remissions of cyanotic symptoms noticeable in nearly all cases. In some malformations the possibility of well-oxygenized blood circulating exists, but in many others it is precluded by the nature of the malformation, as in the case above recorded. Why, then, and how, do the remissions occur? Can any one enlighten me? It is manifestly impossible that when both septa are deficient pure arterial blood should at any time circulate, yet in this case, during the first eighteen months of life, the remissions were apparently complete, and often no cardiac murmur could be detected. That the treatment mitigated the symptoms and prolonged life I have no doubt. For some months the patient took morphia in infusion digitalis with marked benefit, the paroxysms becoming more severe and lasting longer whenever the medicine was omitted for a day. On several occasions when the cardiac disturbance was particularly intractable, marked benefit was derived from the use of chloral hydrate in hypnotic doses.

CATTLE AFFECTED WITH CANCER.—The Sanitary Inspector of Chicago announces the discovery of numerous cases of cancer (?), generally of the tongue, among the stock-yards of that city.

DEATH OF AN OLD PRACTITIONER.—On October 7th Dr. John C. Tibbets, aged ninety, died at his home in Warsaw, N. Y. He claimed to be the oldest continuous practitioner in the State, if not in the United States, having been engaged actively for seventy-one years in his profession. He was graduated when only eighteen, and began practice with his father at Warwick, R. I. He was United States Examining Surgeon for many years.

MEDICAL EXAMINERS IN PLACE OF CORONERS IN RHODE ISLAND.—A bill was introduced into the Rhode Island Legislature last May abolishing the coroner system and substituting medical examiners as in Massachusetts. The bill under the rules passed over to the December session. At the quarterly meeting of the Rhode Island State Medical Society, the subject was discussed,

and the bill, in its general features, was unanimously approved. Dr. Williams, of Boston, an honorary member of the Society, was present, and explained the medical examiner law of Massachusetts. This law, he said, worked to entire satisfaction and with manifest economy. The cost to the State is about two-thirds that of the old coroner system, and in large cities where the services of the examiner are required it is even less. The results to the prosecuting officer are much more satisfactory. The report is made by an expert in scientific legal style, instead of in the miscellaneous way so common under the coroner system.

THE PROPHYLACTIC USES OF CATS.—Dr. F. Bradnack, of New York, sends us the following curious history: "Some time ago I was hastily called to a house on Eighty-sixth Street. Briefly stated, what I found was as follows: A young woman (German), having occasion to go out, had left her infant, aged sixteen months, laid upon a pillow by an open window. Her carelessness was promptly rewarded, for she had not been gone three minutes before the child fell out of the window and struck upon a stone pavement about twelve feet below. It was picked up and carried into the house by one of the neighbors. I found, upon examination, that the back (dorsal and lumbar regions) was badly contused. Naturally expecting to find the skull fractured, I made a minute and careful exploration. To my astonishment, there was neither cranial fracture nor displacement. There was not even a scalp abrasion apparent. Puzzled at this, I asked if any one had actually seen the child fall from the window. This question produced one of the neighbors, an intelligent man, who deposed as follows (I quote the substance of his statement): 'The reason why the child's head was not smashed by striking the pavement is that exactly under the window from which it fell there lay asleep a large tom-cat. The head of the child struck squarely upon the belly of the cat. I was standing close by at the time, and saw it.' Upon my expressing some incredulity at so unprecedented a coincidence, the man asseverated that the facts were exactly as he had stated them. I dressed the child's back with simple anodyne and emollient applications, and prescribed a small quantity of chloral hydrate to insure sleep. The next day, barring the superficial abrasions over the dorsal and lumbar regions (which soon after healed entirely), the child was doing quite well. What was perhaps fully as strange is the fact that the cat was sitting on the hearth, and also doing 'as well as could be expected under the circumstances.' From subsequent inquiry, I learned that another man also witnessed the fall. He was considered a trustworthy person by his neighbors. He fully confirmed the testimony of the first narrator. In short, there is no reason for doubt concerning this remarkable coincidence. They who are too hasty in denouncing the feline race as a nuisance would perhaps do well to bear this case in mind."

REGISTERED PHYSICIANS IN LOUISIANA.—In accordance with a law passed by the Legislature in 1882, it is now obligatory upon all physicians practising in Louisiana to be registered by the Board of Health. The number of physicians thus registered up to July, 1883, was 559, of whom 156 were practising in New Orleans. Two parishes are reported as being without a duly qualified physician, and in Union Parish all the practitioners, to the number of nine, are registered as without diploma, their qualifications being a more than five years' practice before the new law came into effect.

THE SANITARY COUNCIL OF KENTUCKY.—The second semi-annual meeting of the Sanitary Council was held at Glasgow on Tuesday, October 2d. In the absence of the president, Dr. J. A. Dixon, Dr. B. H. Grinstead was called to the chair. Dr. J. N. McCormack, of Bowling Green, Secretary of the State Board of Health, was elected permanent secretary. Dr. Grinstead, Health Officer of Glasgow, read a carefully prepared paper on

"The Adulteration of Medicines," with special reference to the prevention of such adulteration. This was followed by a paper, by Dr. J. S. Linch, of Glasgow, on "The Management of Small-pox, and its Restrictions." Both of these papers elicited interesting discussion, the speeches being limited to five minutes. Dr. J. W. Holland, of Louisville, presented an elaborate paper on "The Cause and Prevention of Cholera," citing the history of the disease in many cities and towns of the State in 1873, to support the commonly accepted view that the disease is miasmatic, contagious in character, and was to be controlled by cleanliness, isolation, and the careful disinfection of the alvine discharges, and everything with which they come in contact. The discussion of this paper concluded the day session. A large and intelligent audience greeted the council at the evening session. Dr. R. M. Alexander read a carefully prepared paper on "The Reasons for Sanitary Legislation," and was followed by Dr. Pinckney Thompson, of Henderson, with an excellent and thoroughly practical paper on "Domestic Hygiene." Dr. Holland read a paper by Prof. L. Eddy, of Danville, on "The Reciprocal Relations of the People and the State Board of Health." Dr. McCormack presented "A Plea for the Teaching of Hygiene in the Schools." Prof. A. W. Mell, of Glasgow, made an address on "School Hygiene." The Council adjourned to meet in Bardstown on the first Tuesday in April, 1884. The Sanitary Council is a voluntary organization, open to all persons in the State interested in the question of public health, and is purely advisory and educational in character. This was the first working meeting, the initial meeting having been held in Louisville in March last, and the attendance and interest manifested encourages the originators of the organization to expect much good from it. It was called, and the first meeting held under the auspices of the State Board, but the intention is to keep it entirely distinct from that body. The experience at Glasgow teaches that the work of the Council cannot be gotten through with in one day and night, and the programme for Bardstown will be so arranged as to give more time.

STATEMENT OF DEATHS FROM YELLOW FEVER AT VERA CRUZ, 1881, 1882, and eight months in 1883.

DEATH FROM AN OVERDOSE OF CARBOLIC ACID.—A death was caused recently in the Hôpital Tenon of Paris from the careless administration of carbolic acid by one of the nurses. The victim was a young girl, suffering from typhoid fever, for whom a potion containing phenic acid was ordered. The head nurse, whose duty it was to administer the medicines, although she had nothing to do at the time, told one of her assistants to measure out the dose. The latter did so, using the wrong measuring-glass, and gave the poor patient over an ounce of pure carbolic acid.

THE USE OF LARGE DOSES OF ACONITIA IN SCIATICA.—Dr. J. D. Mulhane writes to us in reference to Dr. Tilton's criticism of the dosage of aconitia. He states that he had an obstinate case of sciatica in a man, a hammerer on the Pan Handle Railroad. He gave him finally aconitia in doses of gr. $\frac{1}{8}$ three times a day, or gr. $\frac{1}{4}$ per day. The patient was relieved and able to resume his work.

THE ARCHITECTURE AND FUNCTIONS OF THE CEREBELLUM.¹

BY AMBROSE L. RANNEY, M.D.,
NEW YORK.

The cerebellum.—The cerebellum or "hinder-brain" consists of two lateral hemispheres, joined together by an intermediate portion, which is called, from a fancied resemblance to a worm, the "vermiform process." The peculiar appearance of this process is due partly to its shape and partly to transverse ridges and furrows which are very apparent. When the under surface of the cerebellum is examined, this process appears as a well-marked projection, the "*inferior vermiform process*." On the upper surface it is only slightly elevated, forming the so-called "*superior vermiform process*." In birds as well as in some animals lower in the scale, the vermiform process alone exists.² It is the part first developed in mammals. In most mammals, moreover, it constitutes a distinct central lobe, clearly demarcated from the lateral portions—the hemispheres of the cerebellum.

The *cerebellar hemispheres* are separated behind by a deep notch. Below, a deep fossa (*vallecula*), which is continuous with the notch seen posteriorly, lodges the inferior vermiform process. This hollow also receives the medulla in front and the falx cerebelli behind. The hemispheres are convex on their lower surface and tend to partly conceal the inferior vermiform process; above, however, they are somewhat flattened in the centre and slope downward toward the sides, causing the slightly elevated superior vermiform process to be less distinctly outlined than the inferior.

The cerebellum measures about three and a half inches transversely, about two and a half inches from before backward, and about two inches in depth at its thickest portion, although it thins out at its lateral borders.

The surfaces of the cerebellum are everywhere marked by deep, closely set, transverse, and somewhat curved fissures. These are often of considerable depth, the larger ones concealing many folia which do not reach the surface of the cerebellum. Some of these fissures are better marked than the rest, the most conspicuous being the *great horizontal fissure*, which starts in front at the middle peduncle and extends around the outer and posterior border of each hemisphere, being prolonged into the posterior notch where it joins with its fellow of the opposite side. This fissure separates the cerebellum into an upper and lower portion, which correspond to the upper and lower surfaces. Each of these portions are subdivided by fissures, somewhat more distinct than the rest, into small lobes. The names of these lobules can be found in any work upon descriptive anatomy. The *tonsillæ* and *floculi*³ are the more important. The vermiform process, or "worm," is also subdivided into lobules. Physiological experiment or pathological research has not yet positively located any special functions in these lobules, so that they are of use chiefly in describing

the situation of lesions of the cerebellum and the course of fibres to the cerebellar cortex.

Sections made through the substance of the cerebellum show a beautifully foliated or arborescent appearance, named "*arbor vitæ*," in consequence of the medullary or white substance of the ganglion being prolonged into the laminae. The main branches of the medullary substance, or groups of them, correspond to the lobules of the cerebellum. These are connected, as the cerebral convolutions are, by festoon-like fibres (*fibræ propriæ*). The medullary substance is more abundant in the hemispheres than in the worm (vermiform process). In the centre of each hemisphere a nucleus of gray matter, the so-called "*corpus dentatum*" is seen in all vertical and transverse sections of that region. In structure it resembles that of the olivary body of the medulla oblongata, having a wavy layer of yellowish-brown substance externally, and white matter in its centre. At its upper and inner part this wavy layer is interrupted, so that the plicated capsule is not complete. The fibres which are contained within the processes cerebelli ad cerebrum (superior peduncle of cerebellum) and the valve of Vieussens may be traced, in part, to the corpus dentatum. Stilling, who has made elaborate researches respecting the minute structure of the cerebellum, describes three other collections of gray matter within the white centre of the hemispheres. These are named the "*nucleus emboliformis*," the "*nucleus globosus*," and the "*nucleus fastigii*." These nuclei are not distinctly isolated in all parts, but are connected, here and there, with one another and with the corpus dentatum. Their functions are not yet determined. The "*nucleus fastigii*" is often called the "nucleus of the ventricular roof." It is situated in the white mass of the worm, and lies in the roof of the fourth ventricle. It probably receives fibres of the *auditory nerve-root* and the *trapezium*. This nucleus is separated from its fellows by a thin septum of white matter. The two other nuclei described by Stilling lie in intimate relation with the dentate nucleus of the hemisphere.

The cerebellum, as a whole, is described as possessing *three peduncles*. These are collections of nerve-fibres which pass out from, or into, the substance of the hemispheres. The *superior peduncles* (*processi cerebelli ad cerebrum*) are directed upward and forward from the mesial part of the hemispheres. The *middle peduncles* (*processi cerebelli ad pontem*) emerge from the lateral part of the hemispheres and pass to the pons varolii. The *inferior peduncles* (*processi cerebelli ad medullam*) escape from the hemispheres of the cerebellum between the other two; pass forward, outside of the superior peduncles to reach the lateral wall of the fourth ventricle; and then turn sharply downward to become the so-called "*restiform bodies*" of the medulla oblongata. Each of these processes will be considered separately.

We are now prepared to consider the minute structure of the cerebellum and its processes. The various theories which have been advanced in regard to the probable functions of this ganglion can be intelligently discussed only after a knowledge of its connections with other regions of the cerebro-spinal system. Experimental physiology frequently conflicts with the observed effects of pathological lesions of the nerve-centres. This is due chiefly to the fact that many of the so-called "ganglia" of the brain, which were regarded by the older anatomists as homogeneous structures, are now known to consist of

¹ A part of a course of lectures delivered before the students of the University of the City of New York.

² The *vermiform process* appears to be a complete ganglion in itself, associated with its own nerve-tracts. The *cerebellar hemispheres* are added, in the higher grades of animals, in proportion to the development of the cerebral lobes.

³ The *floculus* is believed by some authors to be directly associated with a fasciculus derived from the pneumogastric nerve.

collections of distinct nuclei or "centres," each of which may possess different peripheral connections; moreover, important nerve-strands, which are often connected with remote collections of nerve-cells, also traverse these nodal masses of gray matter, in some instances.

The cerebellar cortex.—The external gray matter of the cerebellum differs in its microscopical appearance from that of the cerebrum, which has been described in a previous lecture. It consists of three layers: an outer, consisting of both cells and fibres; a middle, consisting of large cells, termed the "corpuscles of Purkinje;" and an inner, which is reddish-gray in color and of a granular structure.

In the *outer layer* most of the fibres have a direction at right angles to the surface of the cerebellum. The greater proportion of these fibres are simply the prolongation of the processes of the large cells of the middle layer (cells of Purkinje). Others are fine, tapering fibres, which seem to rest by a broad base on the pia mater, which covers the outer layer. These fibres make up a dense felting, enclosing free nuclei and scattered cells. The cells of this layer are granule-like bodies, the larger of which are apparently connected with the processes of the cells of Purkinje. The smaller probably belong to the matrix; the larger are supposed to be nervous in function. Along the innermost portion of the outer layer nerve-fibres may be also demonstrated, which run parallel with the surface of the cerebellum.

The *middle layer* is characterized by the peculiar cells¹ found embedded in it—the "cells of Purkinje." Most of these cells are flask-shaped, although a few are irregular in form. The long axis of the cell is placed at a right angle to the free surface of the cerebellum. Their diameter varies from $\frac{1}{800}$ to $\frac{1}{1000}$ of an inch. Two sets of processes may be demonstrated as arising from these cells, viz., one passing through the outer layer of the cerebellar cortex and one passing through the inner layer. The former are of large size and are connected, in some instances, with the corpuscles of the outer layer; others pass directly through the layer to become lost at its surface. In either case, they subdivide repeatedly in their passage through the outer layer. The inner set of processes are fine and undivided, and pass into the granule-layer, where some probably become continuous with the axis-cylinders of nerve-fibres composing the medullary portion.

The *inner layer*, called the "granule layer," lies next to the medullary centre of the cerebellum.² It consists of granule-like corpuscles which are imbedded in groups in a gelatinous matrix. Nerve-fibres can be demonstrated to join with the processes of the cells of Purkinje within this layer. The cells of this layer are both round and angular. Each consists of a nucleus, a thin envelope of protoplasm, and processes which unite with the plexus of nerve-fibres in its vicinity. They measure from $\frac{1}{2500}$ to $\frac{1}{4000}$ of an inch.

It will be evident, after this hasty description, that the cortex of the cerebellum differs markedly from that of the cerebrum, in spite of the various structural types of the latter. The cells of Purkinje are characteristic of the cerebellum alone. The number of layers is less than in the cerebral cortex. We are apparently justified in attributing to the cerebellum some functional attributes of a special type, because similar anatomical elements are to be found in no other region. The theories which have been advanced respecting the functions of this ganglion will be considered later.

In cross-sections of each fold or lamina of the cerebral cortex may be seen a central medullary or white portion, resembling the stem and diverging branches of a twig, with its attached leaves. This "*medullary centre*" can be

shown to consist of bundles of fibres which run parallel with each other or interlace, until they turn obliquely into the gray matter of the cortex. It is still undecided whether these fibres terminate in the "granule layer" of the cortex, becoming joined to the axis-cylinder processes of the cells of Purkinje, or by a union with the plexus of fine fibres described as existing in the outer layer.

The central white substance of the cerebellum.—The peduncles of the cerebellum have been mentioned in the early part of this lecture, but much remains to be said respecting the probable course of the fibres contained in each, during their passage through the white or medullary centre of the cerebellum. The course which they pursue outside of the limits of this ganglion will also merit subsequent attention.

The fibres of the *superior peduncle* (Fig. 1) can be traced almost entirely into the interior of the "nucleus dentatum;" although a few can be demonstrated to pass around the outer side of this central mass of gray matter without entering it, and some mesial fibres can be shown to enter directly into the white substance of the vermiform process. As was stated to be the case with the corpus striatum and the optic thalamus, it is probable that a few of the fibres which apparently enter the substance of the nucleus dentatum do not become joined with the cells of that body, but simply pass through it to go to the cerebellar cortex; on the other hand, it is equally probable that most of the fibres which enter it become associated more or less intimately with the cells found within that body, and that they are subsequently continued to a peripheral termination in some part of the cortex. The fibres which enclose the nucleus dentatum are so matted together into a feltwork that it is impossible to trace the course of even distinct bundles from their entrance into the cerebellum to their termination in the cortex.

The fibres of the *middle peduncle* leave the pons, to enter the lateral part of the white substance of the cerebellum as two main bundles. One is composed of the superior transverse fibres of the pons; the other consists of the lower transverse fibres of the pons mingled with those of the *inferior peduncle* of the cerebellum (*restiform body of the medulla*). The upper bundle passes obliquely downward over the lower, and enters the lateral and anterior portions of the medullary centre of the hemisphere. The lower bundle, after joining with the fibres of the restiform body of the medulla oblongata, turns upward, and radiates into the upper part of the medullary centre of the corresponding hemisphere of the cerebellum and the upper part of the vermiform process. Stilling states that the fibres of the restiform body pass, in part, into the nucleus dentatum, while the rest curve over the nucleus, the so-called "semicircular fibres."

Finally, certain *commissural fibres* are described by Stilling as existing in the cerebellum. These may be divided into two sets. The first are analogous to the commissural fibres of the cerebrum, crossing the median line and probably joining homologous regions of the cerebellar cortex in the two hemispheres; the second analogous to the collateral fibres of the cerebrum, connecting one lamina of the cortex with another and arching around the fissures between the laminae. The latter set are confined to one hemisphere and do not cross the median line of the cerebellum. The direction of these fibres is transverse to that of the "peduncular" cerebellar fibres.

It is evident, therefore, that the general arrangement of the cerebellar fibres bears a striking resemblance to that of the cerebrum; the *nucleus dentatum*, *olivary body*, *red nucleus*, and *gray matter of the pons* being the analogues of the basal ganglia of the cerebrum, and the "radiating," "commissural," and "associating systems" being similar in many respects.³ The cerebellum, like the cerebrum, may be said, therefore, to exhibit three

¹ The bodies of these cells are colossal (sixty to seventy millimetres in length, and twenty to thirty millimetres in thickness). They appear to be enclosed within a loose-fitting capsule, formed of connective-tissue fibres (Obersteiner).

² The striking resemblances between this layer and the granular strata of the olfactory lobe have been commented upon by Meynert. The cells of this layer are regarded by Gerlach as connective-tissue elements; by Henle and Merkel as lymphoid elements; and by Stilling as small multipolar nerve-cells.

³ See article by the author in the New York Medical Journal, April, 1880.

so-called "projection systems" of fibres, as follows: 1, the *inner* projection system, the fibres of which serve to connect the cortex of the cerebellum with the nucleus dentatus of the same hemisphere and the olivary body, the red nucleus of the tegmentum, and the anterior gray substance of the pons varolii of the opposite side; 2, the *middle* projection system, the fibres of which connect the enumerated masses of gray matter with the gray matter of the spinal cord; 3, the *outer* projection system, the fibres of which are included in the expansions of the central tubular gray matter to the periphery of the body by means of the spinal nerves.

The following diagram will help to make certain points clear regarding the intimate structure of the cerebellum and its connections with adjoining parts. It is, of course, purely schematic, but, if used in connection with actual representations of the parts, it will prove of great value in comprehending many statements which are to follow. In this diagram the shaded parts represent collections of gray matter, the lines indicate the direction and extent of individual sets of nerve-fibres which are in direct communication with the shaded masses.

FIG. 1.—A Diagram designed to Illustrate the Various Sets of Fibres comprised within the Cerebello-Spinal System. (Modified from Ross.) C.R., crusta cruris; T.E.G., tegmentum cruris; A.S., aqueduct of Sylvius surrounded by the tubular gray matter; S.N., substantia nigra; R.N., red nucleus of the tegmentum; G.M.P., anterior gray matter of the pons; C.C., cerebellar cortex; N.D., nucleus dentatus; O.B., olivary body; C.N., clavate nucleus; T.N., triangular nucleus; D.C.T., fibres of the "direct cerebellar tract" of the spinal cord; P.R.Z., fibres of the "posterior root zone" of the same; G., fibres of the "column of Goll"; 1, cerebro-cerebellar fibres; 2, fibres from the red nucleus of the tegmentum to the dentate nucleus of the cerebellum; 3, fibres from the red nucleus of the tegmentum to the olivary body of the opposite side; 4, fibres from the cerebellar cortex to the dentate nucleus; 5, fibres from the dentate nucleus to the olivary body of the opposite side; 6, fibres from the cerebellar cortex to the anterior gray nucleus of the pons of the opposite side; 7, fibres from the cerebellar cortex to the anterior gray nucleus of the pons of the same side; 8, fibres of the direct cerebellar tract; 9, fibres connecting the clavate nucleus and the olivary body of the same side; fibres connecting the triangular nucleus and the olivary body of the same side; 11, fibres passing from the olivary body to the horns of spinal gray matter; 12, fibres passing from the anterior gray matter of the pons to the horns of spinal gray matter; 13, fibres passing from the red nucleus of the tegmentum to the anterior horns of the spinal gray matter; 14, fibres escaping from the spinal cord through the anterior root of a spinal nerve; 15, fibres of the posterior root of a spinal nerve entering at the posterior horn of the spinal gray matter. The dots in the cut end of the spinal cord, near to 15, indicate the relative position of the different tracts with which they are connected. A, A, A, represent fibres which are destined to connect different convolutions of the cerebellar cortex (*fibre propriae*).]

The arrangement of the middle projection system of fibres pertaining to the cerebello-spinal apparatus is less definitely settled than that of the cerebro-spinal. It is probable, however, that the cerebellum receives afferent sets of fibres (sensory) from the spinal cord, and gives off also certain efferent sets of fibres (motor), which are brought into more or less direct communication with the motor tracts of the crura, pons varolii, medulla, and spinal cord.

The *afferent* fibres of the cerebellum probably reach that ganglion through the following channels:

1. By means of the *columns of Goll* (G.), which terminate in the so-called "*clavate nucleus*" (C.N.).
2. By means of the *columns of Burdach* or the *posterior root zone* (P.R.Z.) of the spinal cord, which seems to be structurally related with the so-called "*triangular nucleus*" (T.N.).
3. By means of fibres which connect the *triangular* and *clavate nuclei* with the "*olivary body*" of the corresponding side of the medulla oblongata (9 and 10).
4. By means of the "*direct cerebellar tract*" of fibres (D.C.T.) which is found within the lateral column of the spinal cord near to the extremity of the posterior horn of the spinal gray matter.
5. By means of fibres connected with the *auditory*, and possibly with the *sensory root* of the *fifth cranial nerves*. The auditory fibres are associated chiefly with the corpus dentatum and the nucleus fastigii. They decussate either in the medulla or cerebellum. They pass through the auditory nucleus before entering the cerebellum.

The *efferent* fibres of the cerebellum are probably comprised within the following fasciculi:

1. Bundles of fibres which connect the *dentate nucleus* and the *cerebellar cortex* with the *corpus striatum*, by means of the "*processus cerebelli ad cerebrum*." This bundle is also in intimate relation with the red nucleus of the tegmentum, and probably is structurally related with some of the nerve-cells found in that nucleus (2 in Fig. 1). Luys believes that the corpus striatum is charged, when its nervous force becomes exhausted, by means of this process of the cerebellum. If this be the case, the cerebellum exerts some influence upon the motor impulses emitted from the cerebral hemispheres; because all such impulses are probably modified within the corpora striata before they are transmitted to the more distant parts of the nervous apparatus (the gray matter of the spinal cord, and the spinal nerves). The probable relations of cerebral and cerebellar influences upon muscles will be discussed later.
2. Fibres which connect the *red nucleus of the tegmentum* with the anterior horns of the spinal gray matter (13).
3. Fibres which connect the *olivary bodies* of the medulla oblongata with the anterior horns of the spinal gray matter (11).
4. Fibres which connect the *anterior gray substance of the pons Varolii* with the anterior horns of the spinal gray matter (12).

FIG. 2.—A Diagrammatic Section of the Spinal Cord, designed to Illustrate the Situation of Various Nerve-Tracts. (Seguin.) A, anterior fissure; P, posterior fissure; 1, columns of Goll; 2, columns of Burdach; 3, direct cerebellar column; 4, crossed pyramidal column; 5, lateral column; 6, anterior fundamental column; 7, direct pyramidal column; 8, posterior gray horns; 9, anterior gray horns; shaded part, aesthesic system; unshaded part, kinesic system.

The diagram of the various segments of the spinal cord, to which I now direct your attention, will help, if used in connection with the preceding one, in comprehending the course of the various bundles of fibres mentioned.

¹ If the brain be considered as a whole, fibres passing from the cerebellum to the cerebrum by means of the superior and middle peduncles, as well as those passing to the tubercular quadrigemina, by means of the valve of Vieussens, may be classed as *afferent* fibres. Spitzka denies the existence of *efferent* cerebellar fibres (outside of the superior and middle peduncles).

From the imperfections of our present knowledge, much that is stated here regarding the exact course of the afferent and efferent impulses of the cerebellum must be somewhat conjectural. The results of experimental physiology and of pathological research are not, and cannot well be, of a positive character. Many conflicting theories have been at different times advanced regarding the functional attributes of this ganglion. These will be considered when the anatomical data have been fully presented.

Processus cerebelli ad cerebrum (processus e cerebello ad testes, superior peduncle of cerebellum).—In connection with previous lectures,¹ chiefly in those which treated of the corpus striatum and the optic thalamus, the relation of the cerebellum with the medullary portion of the cerebrum by means of special fibres has been mentioned. The special group of fibres which compose the *processus cerebelli ad cerebrum* appear to start anteriorly from among the radiating fibres of the cerebrum and are forced apart, in the region of the crus, above the corpora quadrigemina, by the introduction of a nodal mass of gray matter, characterized by nerve-cells and granular material, the so-called "red nucleus of the tegmentum." In the region of the lower half of the superior corpus bigeminum this tract appears as a simple bundle of fibres, which are not destitute of nerve-cells but whose circumference is much less than in the region of the red nucleus. The nerve-cells of this bundle are of extreme size, and appear to be arranged parallel with the *vessels* of that region rather than with the nerve-fibres. In some cases they bend to fit the angles of the branches of the arteries, and send out long prolongations that run longitudinally along, and probably in their walls (Meynert). Even in the "red nucleus," this arrangement may be demonstrated. The presence of nerve-cells within this tract does not cease until after its decussation and its escape from the corpus quadrigeminum. It yet remains to be demonstrated whether the crural portion of the *processus cerebelli ad cerebrum* is the only seat of a peripheral termination of nerve-cell processes in the walls of capillaries in the midst of the central organ.

If successive cross sections of the region occupied by this tract be studied, it will be seen that the *processus cerebelli ad cerebrum* of either side approaches the median line and that the fibres eventually decussate. The region occupied by these decussating fibres lies between the "posterior longitudinal fasciculus" and the "stratum lemnisci," the remaining bundles of spinal fibres which enter the tegmentum having been crowded away by them. After their decussation, these fibres pass outward until they reach the inner surface of the inferior lamina of the lemniscus, which forms a sort of protective cover for them. Meynert has compared the outline of the two processes to the form of a horse-shoe, whose opening is directed backward. This opening represents an area which embraces those fibres of the "tegmentum cruris" destined for the spinal cord lying between the stratum lemnisci and the posterior longitudinal fasciculus. The decussating fibres of the cerebellar tract force their way among the fibres of the tegmentum cruris to reach their lateral position; hence, cross sections made at different altitudes show ever-varying relations between these fibres and those of the tegmentum. Stilling and Arnold, who have made a special study of the course of the fibres of the *processus cerebelli ad cerebrum*, differ as to the completeness of the decussation, the latter denying that all the fibres cross the median line. Meynert confirms the view, originally advanced by Stilling, that the decussation is complete.

After the decussation of its fibres, each *processus* disengages itself, both superiorly and externally, from the fibres of the tegmentum cruris in which it was embedded. Opposite to the point of greatest convexity of the pons Varolii, it becomes uncovered by the inferior lamina of

the lemniscus. Later in its course it becomes buried in the white substance of the cerebellum, and finds an ultimate connection with the "nucleus dentatus," the central mass of gray matter within the cerebellar hemisphere.

(To be continued.)

NOTES ON GYNECOLOGICAL THERAPEUTICS.

By HORATIO R. BIGELOW, M.D.,

WASHINGTON, D. C.

Constipation.—Women seem to be especially subject to intestinal torpidity. Their sedentary lives, and the manifold disturbances of the uterus, or of the uterine adnexa, which are of very common occurrence among them, seem to be conducive to irregularity. Carelessness, too, in observing fixed hours, the necessary prerequisite to the formation of a habit which impresses itself upon normal peristalsis, is not infrequent. Many instances of obstinate constipation of long standing have yielded to simple rules of observance. A woman should be taught to go to the water-closet at a stated hour each morning, and wait patiently, without undue straining or nervous agitation, the consummation of her desire. This routine, faithfully carried out, fixes itself upon the intestinal function, so that the bowels become accustomed to a daily movement at a definite hour. But there are cases, especially in women with retroverted, prolapsed, or enlarged uteri, in which there is always a residuum left just above the internal sphincter. There is inability to expel it, either because the fundus uteri pressing upon the rectum, occludes the normal lumen—expulsive efforts causing a high degree of pain in the womb, and increasing the amount of prolapse, which obtains in all conditions of retroversion to a certain extent—or else from loss of tone in the lower bowel itself. Many patients of regular habits frequently complain of this unsatisfied desire. The wearing of pessaries or of cotton tampons will occasionally bring about such a result. To overcome this, to insure a satisfactory movement which shall cause no uterine inflammation, which shall empty the rectum entirely, and which shall counteract the astringent properties of iron tonics, has been a favorite field of investigation. Impacted feces, from an insufficiently emptied rectum, will act as a foreign body, and give rise to much constitutional disturbance. I have lately been in the habit of using, and with complete satisfaction, a very domestic remedy, which I venture to give the profession: One-half pound of figs, one ounce pulverized senna, one ounce pulverized sulphur. Chop the figs up as fine as possible, then add the senna and sulphur, and two tablespoonfuls of granulated sugar. Knead as one would dough, and moisten with a little essence of vanilla. Roll out and cut into thin pieces the size of a quarter of a dollar. Take one-half of one of these tablets, or even a whole one if necessary, as occasion may require. This will bring about a natural movement without strain or pain of any kind. It creates no uterine irritation and does not force the uterus low down into the pelvic cavity as many such preparations are apt to do. If the liver be implicated, I have had good results from parvules of podophyllin, as made by Warner of Philadelphia, given at short intervals.

Malt.—Hoff's malt, taken after meals, is a good tonic, but not, strictly speaking, a digestive. It acts admirably in the marasmus of uterine affections, where the object is to build up the system with wholesome nourishing food. But there is a certain class of cases in which dyspepsia is not only a prominent, but an aggravated and pertinacious symptom—a dyspepsia that is purely reflex, not due to any primary derangement of the stomach, liver, or bowels, and which gets better only as its exciting cause improves. I have used many preparations of malt with varying results. A convenient test is to place in a test-tube a given amount of starch, then add a teaspoonful of malt, and notice the time which elapses be-

¹ Published in the *Journal of Nervous and Mental Diseases*, February and April, 1883.

fore the starch is entirely digested. Then add a few drops of iodine, and if the characteristic reaction takes place, we may be sure that there is something lacking in the malt, otherwise we would have no purple or blue color. Saliva, too, is related to the digestion of starch, just as the pancreatic juice emulsifies fats, and the gastric juice digests proteids. As contradistinguished from Fothergill's assertion that malt extracts act better in the presence of an alkali, it is a fact that their greatest diastolic power is in the presence of acids. To preserve them from deterioration glycerine is used in large quantities. Reed & Carnrick's maltine, when it first made its bow to the public, seemed to meet all demands. But latterly, whether owing to a larger amount of heat being used in its preparation, so as to avoid the use of so much glycerine, which costs about one hundred dollars per barrel, or to some other cause to me unknown, it has fallen below the standard, having little or no power over starch. Loeffland's malt, an expensive imported preparation, is much more active, but does not entirely digest the starch in the test-tube. Trommer's malt digests the starch rapidly and gives no reaction whatever to the iodine test. This latter, therefore, I have used latterly, and have always found that it accomplished what I desired. This test, together with microscopic examination, were made and verified by one of our ablest chemists and microscopists in Washington. Now I do not pretend to say that an extract of malt is indicated in all cases, but I do believe that much disappointment has arisen from the employment of an inferior article, which has nothing to commend it but a flaming advertisement. There are patients who grow much better under the judicious employment of malt, and there are others who receive no benefit whatever from any preparation. If the dyspepsia be intercurrent with a generally weakened constitution, so that all the functions are tardily carried on, the elixir of iron, quinine, and strychnia will be found to subserve an admirable purpose. If it be due to the excitability of the stomach, which occurs after frequent vomiting, such as occurs in the intra-menstrual period and is due to hydro- or pyosalpinx, or to a subacute inflammation of the peritoneum, or to an ovaritis, small quantities of milk and lime-water, frequently administered, followed by finely minced raw beef, will be indicated. A cup of *hot* water will frequently allay the nausea, pain, and craving for food. Of course such suggestions as will come to the mind of every intelligent practitioner in regard to food should be urged with force. A weakened stomach is sure to rebel against a dose of hot bread or highly seasoned fatty food. I am of the opinion that such women should take their most substantial meal at midday, and be satisfied with a light supper.

I wish to call especial attention to the Carlsbad Sprudel Salt (either the new salt, or the Eisenquelle, or Karlsbad, or the Giesshübler Sauerbrunn) in the treatment of dyspeptic women with yellow eyes, sallow skins, and a general torpidity of the liver and intestines. A heaping teaspoonful in a half-tumbler of warm water, gives an easy action, promotes the flow of bile, and permits the digestion of suitable food. Dr. Hlawacsek says of them that coming into contact with the mucous membrane of the intestinal canal, they act: (1) As animating, modifying, and soothing the nerves of the part; (2) as healing with regard to the mucous membrane of the ventricle and duodenum; (3) as removing acidity; (4) as purging. By being absorbed into the system they dissolve: 1, The tenacious and thick bile contained in the biliary ducts, and are even capable of dissolving gall-stones in course of formation; 2, they remove congestion of the blood generally, but chiefly of the mesenteric vein; 3, they disperse accumulated lymph; 4, remove fatty tumors due to fibrous inflammatory products; 5, they improve and ameliorate the condition of the blood and lymph, chiefly when it shows itself by an accumulation of albuminous azotic compounds. They give dark bilious mo-

tions, thus freeing the system from the superfluous accumulation of the compounds of carbon and hydrogen. Nothing equals them in "plethora abdominis." The Schlossbrunn and the Marktbrunn are cold waters, and are the ones upon which patients usually begin. The Sprudel salts, however, are most in vogue in this country. Their action is not purgative in the strict meaning of the word, and their use need not be discontinued during menstruation. The Sprudel salt contains in 100 parts: Sulphate of soda, 37.69; chloride of sodium, 0.39; carbonate of soda, 5.99; traces of sulphate of potash, and 55.52 parts of water. One or two teaspoonfuls may be added to the imported Karlsbad, Selters, or soda-water. The Eisenquelle is a chalybeate water, and should be mixed with one-third of Giesshübler-Sauerbrunn to prevent cardiac pain.

The *left side pain*, so common among many women, may be due to the dragging on the pleuro-colic ligament, attributable to an overloaded colon, in which event the remedy is plain.

Hot water vaginal douche is of pre-eminent value. In ovaritis, lymph-adenitis, inflammations, and in nearly all the diseases of the uterus and its appendages, nothing will be more grateful. For this purpose I make use of Merriam's arrangement. It is less fatiguing to the patient than the fountain syringe, while the reservoir holds more water, runs out slower, and can be kept at an even temperature. The pelvis being elevated, the water reaches every part of the vaginal envelope, which it cannot do with the ordinary method. Its value may not be overestimated.

Electricity.—I have used galvanism, from eight to fourteen cells, with a current interrupted six times per second, in some cases of ovaritis and salpingitis, with marked benefit. Dr. Mundé used it with an electrode in the rectum and a large sponge over the lower abdomen, with some success, in a case of lymph-adenitis. In cases of spasmodic (reflex) contraction of the gall-duct, due to ovarian trouble, giving rise to symptoms of catarrhal jaundice, it has also stood me in good stead. In all instances of lymph formation and exudation it is of great value. The localized and general faradic current is of common use in neurasthenia.

Pessaries.—There are some reasons which almost lead me to believe that pessaries are an abomination. The resultant ease and comfort may be followed by after-suffering, and is continuous only with the wearing of the support. No permanent cure is brought about; the vaginal walls are put upon a stretch, so that they lose their contractility, and can never be relied upon for any natural support to the uterus; the bladder and rectum are both intolerant of the pressure, and the superimposed uterus suffers at the fundus in a large proportion of cases. In retroversion I have found scores of women who complained of rectal tenesmus and pain, irritation at the neck of the bladder, and of a sore spot at the fundus, who were wearing a most carefully adjusted pessary made from exact measurement. In anteversion they accomplish absolutely nothing. The whole principle is wrong. Gehring's pessary is the best I have used in these cases, but it does not cure the flexion. Some women, especially those with lymph-adenitis (see Mundé's article, *American Journal of Obstetrics*, October, 1883), can wear no support whatever. So far as I possibly can I rely upon pneumatic pressure, replacement, and astringent tampons. In other cases I use the pessary for want of something better, but always with fear and trembling. I never use the stem, for I cannot see how it will cure a flexion, and the attendant risk is great.

Iodoform.—Useful in quieting nausea, and as suppository in ovaritis and inflammation of the uterus. Also of service in lymph-adenitis. Of this latter I know nothing from experience. I have never diagnosed a case, and am indebted to Dr. Mundé's article for pretty much all that I know about it. As a quieting lotion I use a preparation introduced by Dr. Carrier, of iodoform, eucal. glob. (fl. ext.), and glycerine. Iodoform is a valuable alterative, and useful as a topical application in eroded or ulcerated surfaces.

CHLOROFORM NARCOSIS DURING SLEEP.

By JOHN H. GIRDNER, M.D.,

NEW YORK.

IN THE RECORD of April 28, 1883, I published an account of a number—five—of unsuccessful attempts to anæsthetize persons while asleep, without awakening them, by impregnating the inspired air with the vapor of chloroform. I wish now to add to this record eighteen other experiments made by myself, with the kind assistance of Dr. Norris, of this city, House Surgeon to Bellevue Hospital. The date was the night of September 19, 1883.

I.—Boy, aged seven. A small hand-towel, moistened with chloroform, held about twelve inches from the face and slowly brought nearer; at the end of one minute, and when the towel was within about six inches of the face, the boy awoke with a start, and looked around in a frightened manner.

II.—Boy, aged ten. Towel held two feet away, carefully brought nearer; woke in three and one-half minutes with a start.

III.—Boy, aged ten. Towel twelve inches; awoke immediately.

IV.—Boy, aged eleven. Towel twelve inches; awoke immediately.

V.—Boy, aged eight. Towel twelve inches; woke in fraction of a minute.

VI.—Woman, aged thirty-three. Towel held eighteen inches from face; awoke in one minute.

VII.—Woman, aged thirty. Towel eighteen inches from face; awoke in one and one-half minute.

VIII.—Boy, aged two. Towel held two feet from face and slowly brought nearer; awoke at end of three and one-half minutes.

IX.—Man, aged fifty. Towel held three feet from face and very slowly brought nearer. At the end of seven and one-half minutes he showed signs of restlessness, turning in bed and moaning in his sleep, and awoke frightened.

X.—Man, aged twenty. Towel eighteen inches from face; awoke in about three minutes.

XI.—Man, aged twenty-five. Towel twelve inches; awoke in about three minutes.

XII.—Man, aged seventy. Towel two feet; awoke in four minutes.

XIII.—Man, aged twenty-eight. Towel eighteen inches; awoke immediately.

XIV.—Man, aged sixty-two. Towel eighteen inches; awoke in about three and one-half minutes.

XV.—Man, aged twenty-five. Towel two feet; awoke in about three and one-half minutes.

XVI.—Man, aged sixty-four. Towel two feet; awoke in four minutes.

XVII.—Man, aged twenty-six. Towel two feet; awoke immediately.

XVIII.—Man, aged twenty-four. Towel two feet; awoke in three minutes.

Dr. Norris tells me that he has made three other unsuccessful attempts to narcotize children with chloroform while asleep without their awakening.

Since writing my former paper I have received a large number of communications on this subject, both oral and written, from medical gentlemen throughout the country, including many of the oldest and most distinguished surgeons, and in every instance their experience has been identical with my own. Since I last wrote there has also been a number of letters published in this and other journals detailing what at first sight might seem to be successful attempts to transfer persons from natural to chloroform narcosis without an interval of consciousness. Some of these letters have also criticised my experiments, and placed me in a false position. I can but think, however, that this latter mistake was due to superficial reading of my paper.

One gentleman says, speaking of my paper: "In which he takes the ground that chloroform narcosis dur-

ing sleep is impossible." I need not tell any one who reads my paper carefully that there is nothing in it to warrant such an assertion. I was unbiassed at that time, and was, and still am, as anxious to know the truth as any one. Of the dozen or so of cases reported since I last wrote, in which it was claimed that persons had been chloroformed while asleep, I must say they are all unreliable, for the reason that not one of these reports contains conclusive evidence that the patient was ever transferred from the unconsciousness of natural sleep to that produced by breathing chloroform. As a rule, the subjects were children on whom it was desired to perform some slight operation, as the removal of a bean from the nose, cutting off the foreskin, etc., the latter being the most important operation performed on these supposed-to-be chloroformed children. Now, every surgeon who has had much experience knows that such operations as these can be performed on children during natural sleep without their awakening. I have opened a large abscess of the thigh in a small boy, requiring a cut one inch long and half an inch deep, while he slept, without his waking. Dr. Linengood, of Bellevue Hospital, reduced the fragments and applied the proper splints to a fractured forearm of a child, one year old, while it slept in its mother's arms; and Dr. Cunard, of the same institution, amputated a crushed finger for a child and dressed the stump without waking it from a sound sleep; and I have seen a man with half the flesh eaten from one great toe by hungry rats while he slept after a hard day's work in an empty tumble-down house. Thus it is plain that the evidence brought forward by the gentlemen who have reported these cases to prove that their patients were anæsthetized, is not evidence at all. It was possible to have performed all these operations without ever having held a cloth moistened with chloroform near the faces of these sleeping children.

The symptoms of anæsthesia, or narcosis from chloroform, are so well marked, and generally so well understood, that it seems useless to repeat them here. Complete muscular relaxation throughout the body, and the consequent stertorous breathing, the loss of reflex action, as shown, for instance in the failure of the eye to close when the eyeball is touched with the finger, etc., etc., are the symptoms; and when I know they have been produced by chloroform inhalation in a sleeping person without that person being aroused to consciousness, then I will believe that chloroform narcosis during sleep is possible.

HYSTERICAL PSEUDO-PHTHISIS.—In young women suffering from chlorosis and hysteria there is often, according to Dr. Fabre (*Centralblatt für Gynäkologie*, September 8, 1883), a condition simulating phthisis. There is a cough, with expectoration, and even spitting of blood. Physical examination reveals dulness at the apex (usually on the right side), feeble respiration, and occasional râles. The author regards these symptoms as due to a vaso-motor disturbance exciting a pulmonary congestion. Other organs may also be subject to functional disturbances. Obstinate anorexia, gastric pain, occasionally diarrhoea, but more frequently constipation, are not seldom present. The pulse is weak and frequent, like that of fever, although the temperature may be normal. Sometimes, however, there is elevated temperature, but it is only transitory, and regular evening exacerbations are never observed. The expectoration is not purulent, but may be mixed with blood. While in true phthisis there is emaciation, in these cases the patients often increase in weight. Sweating, as a rule, is not met with. The differential diagnosis is often difficult, and the author relates that cases have not infrequently occurred in which a diagnosis of pulmonary consumption was made, but the patient nevertheless recovered. The condition may exist without material improvement for months, or even years.

OXYGEN AND SOME OF ITS COMPOUNDS
AS THERAPEUTIC AGENTS.¹

By SAMUEL S. WALLIAN, A.M., M.D.,

BLOOMINGDALE, N. Y.

PRIESTLEY, who divides the honor of its discovery with Scheele, was the earliest experimenter with oxygen as a physiological agent. He demonstrated that birds, dogs, rabbits, and other animals immersed in an atmosphere of this gas became more lively, active, and brilliant; that dogs trained for the chase could endure greater hardships, and for a longer period, when allowed to breathe the gas for a short time previous to the start than similar animals not thus prepared; and that animals asphyxiated by being compelled to inhale carbon dioxide or other noxious gases were speedily resuscitated if treated immediately with pure oxygen.

Lavoisier confirmed these results, and further demonstrated that the muscles of animals repeatedly subjected to the influence of the gas became very firm, decidedly interfering with their tenderness if speedily designed for the shambles!

These results attracted some attention, and were followed by considerable experimentation on the part of pathologists and physiologists.

Among these early investigators, Dr. Beddoes—not "Eddoes" as quoted in the London *Lancet*—was the first medical man of repute who gave the subject any serious attention. He was assisted by some of the most eminent scientists of his day, including Sir Humphry Davy. These original experimenters labored under serious disadvantages, particularly that of evolving the gas in suitable quantities and of sufficiently pure quality for medical use. After many trials and numerous failures, with not a few accidents, Beddoes declared himself beaten, not by his own loss of faith in the potency of the new remedy, but "by the difficulty of making it available." He did not escape the usual storm of ridicule which invariably greets an innovation, especially if the latter falls short of an immediate and pronounced success. However, his partial success inspired other efforts in the same direction, and he was followed by Drs. Hill, Thornton, Cavallo, and others. Over-sensitive to unkind professional criticism, the latter conducted their experiments in comparative seclusion.

In 1820 Dr. Hill published a brochure reporting the results of these efforts, which, although full of instructive facts and suggestions, attracted little attention, and members of the profession at the present day would be surprised to know that experiments so conclusive were so long since attempted, or that a work of such unusual professional candor was ever issued.

Thornton, Cavallo, and McCormack followed, somewhat later, with still more searching and extensive trials of the gas, and each unequivocally asserted that it would eventually be found a potent and valuable therapeutic agent. They failed to awaken much interest in the subject, and met with the customary storm of ridicule and unreasoning opposition.

Within the last quarter of a century, although little has been said on the subject, various men of note in the profession, including Goolden, Birch, Alexander, Erichsen, Richardson, Demarquay, and others have more or less investigated, occasionally used, and without exception admitted the potency of oxygen in the treatment of disease.

In this country but casual attention has been given to the subject, and beyond an occasional exhibition in some extreme case in hospital practice, little has been reported, the opinion still obtaining with those who have considered the subject at all, that the use of non-atmospheric oxygen in the treatment of disease is of doubtful utility, if not positively dangerous.

Literature on the subject is meagre and unsatisfactory.

Little has appeared in this country, and, as yet, no American publisher has ventured the reproduction of such fragmentary foreign works as have occasionally appeared.

In an article ("Super-Oxygenation as a Therapeutic Measure") in the *Chicago Medical Journal*, vol. xxvi. (1869), pp. 116-120 and 139-152, I gave the results of some of my earlier experience with various super-oxidizing agents.

As a rule, the medical press, both at home and abroad, has shown very little interest in the subject, evidently acquiescing in the prevailing verdict—the only marked exceptions being the London *Lancet* and the *British and Foreign Medico-Chirurgical Review*, in both of which interesting articles have occasionally appeared.

Demarquay's reports to the Academy of Medicine (Paris, 1866)¹ were considered conclusive and satisfactory as far as the subject was covered by his experiments; but have never been reproduced for American readers.

In 1856 appeared in London a small volume under the extremely classical title of "Pneuma-Therapeia." Its author, who was presumed to be McCormack, withheld his name, probably for prudential reasons, since its arguments and reports of cases were addressed more to the public than to the profession; and in an appendix, the Medical Pneumatic Apparatus Company, with the address "46 Regent Circus, Piccadilly, London," advertised to supply both oxygen and the necessary apparatus for manufacturing and administering it.

This little anonymous volume repeated some of Hill's reports of cases treated, including *scrofula*, *dyspepsia*, *chronic dysentery*, *asthma*, *dyspnea*, and *asphyxia*; also referring to the experiments of Beddoes, Davy, Weeks, Cavendish, Coleman, Goodwin, Menzies, Liebig, and others.

Dr. S. B. Birch, of the Manchester Medical School, issued a monograph on the subject of oxygen as a curative agent ("On Oxygen," London, 1857), but it met with very ungenerous criticism and did not find its way to this side. A second edition (London, 1858) was the first contribution to the literature of the subject which commanded any degree of attention.

Ten years later, already investigating the subject of oxygen compounds, I procured a copy of Birch, and am indebted to him for valuable suggestions.

This author says (*op. cit.*, p. 148):

"It (oxygen artificially prepared) is a powerful, really scientific, and agreeable curative agent; is capable of far more extensive range in its application to the rational treatment of chronic disease than, perhaps, any other remedy—is *pre-eminently Nature's own therapeutic*, affording assistance in her own way without opposing the intentions of her ever-present *vis medicatrix*, and is entitled to the position of a *curative* in a variety of intractable diseases, otherwise incurable by any other known means, or tacitly acknowledged to be so; . . . is occasionally *the* remedy, and then the only one worthy of the name, in certain contingencies where life must be (and frequently is) sacrificed by neglecting a fair trial of it."

He adds: "It may with safety be predicted that, sooner or latter, non-atmospheric oxygen will be universally admitted as one of our most valued remedial agents" (*op. cit.*, p. 149).

The verification of this rather sanguine prediction has not yet transpired. Whether on account of the serious and hitherto insuperable difficulties of making the treatment generally available in private practice, or from lack of professional enterprise and ingenuity remains to be investigated.

With the general profession a sort of chronic impression prevails, based on neither science nor experience, that the therapeutic use of non-atmospheric oxygen has been tried and failed?

¹ Read before the Franklin County (N. Y.) Medical Society, June 5, 1883.

¹ See also *Gazette Médicale*, Paris, 1866.

Professor Da Costa says: "Of all the gases oxygen is now being most tried, particularly for the relief of dyspnoea and in low fevers, or during convalescence from low fevers, and in chlorosis. We must await these new trials, for the former experiments were unsatisfactory. But excellent results have quite lately been claimed for oxygen inhalations by Demarquay—who is at present investigating the subject—not only in the conditions named, but in diabetes, in senile gangrene, and in prolonged suppuration" ("On Inhalations," Philadelphia, 1867).

In this country, very little has been heard from these later investigations, except in connection with the subject of antiseptics. In fact, the past decade, in the history of medicine may not inaptly be termed *the age of the germ-craze*. The microscope has monopolized the laboratory, and wellnigh superseded the inductive method. Morbid products have been accorded more prominent attention than vital processes; results studied with the most elaborate minuteness, to the exclusion or ignoring of their underlying causes.

There is no doubt, however, that the shortcomings of impure and carelessly manufactured gas have done more than all else to bring the use of oxygen and its congeners into disregard, if not discredit, and to prevent its timely use by the profession at large.

Again, the usual methods of generating it in a sufficiently pure form for medical use are a conspicuous drawback to its general use by even those who are aware of its value and anxious to avail themselves of it. Some apparatus is required, and careful chemical manipulation, which in time, no doubt, will be delegated to the pharmacist and manufacturing chemist.

At present the process by means of chlorate of potassa and manganese dioxide is the most practical and economical for ordinary purposes. The apparatus required is neither complicated nor expensive. Some care is requisite, but the gas afforded can be secured in a state of almost absolute purity. Various inventors and manufacturers of surgical instruments have, from time to time, brought out unique and ingenious contrivances for evolving and administering the gases, of which might be mentioned one by Dr. Biegel, and that of Galante, of Paris. The Pneumatic Medicine Company, and also Barth, of London, condensed the gas in iron flasks, and added devices for its convenient dispensation.

Fleitmann proposed a process for the rapid liberation of oxygen in a tolerable state of purity (which in a medical sense is nothing short of *intolerable*) by means of calcium chloride and monoxide of cobalt. Since it required that the chloride should be in a state of saturated solution previous to the addition of the cobalt, it was unwieldly and never became popular.

Improving on this suggestion the Messrs. Robbins & Co., of London, succeeded in combining the two substances in the form of dry powder, which is ready for instant use on the addition of simple boiling water, and, it is said, may be preserved indefinitely without deterioration. The process of combining the two substances is reserved by this firm as a manufacturing secret.

An intimate ally of oxygen, therapeutically speaking, is found in *nitrogen monoxide*, N_2O —the "nitrous oxide" of the old nomenclature. It is almost as potent an oxidizing agent as oxygen itself. It supports combustion nearly as well; its specific gravity is greater, and it is distinguished from oxygen by its much greater solubility in water. Doubtless, from this cause, it is much more rapidly and extensively absorbed into the system when inhaled.

It is best known through its general use as a dental anæsthetic. When perfectly pure—a rarer circumstance than need be—it may be inhaled for some time with impunity; in fact it may be safely assumed that the rational use of the pure gas is practically, if not absolutely, free from danger, since out of the millions of instances of its

exhibition to patients of all ages and conditions, the very few fatal cases reported were quite probably attributable to impure gas, irrational or ill-timed administration, or accidental causes.

The anæsthesia induced by its free inhalation, quite unlike that from chloroform, ether, ethyl, bromide, and other anæsthetics, is transient, pleasurable, unaccompanied by a stage of excitation, and is not followed by depression or other unpleasant after-effects.

Under a pressure of fifty atmospheres, it becomes liquid, and at $-120^{\circ} F.$, Faraday succeeded in reducing it to a solid. In the latter form, applied to the skin, it produces a painful, burn-like blister (Fownes).

That it is an oxidizing agent in a marked degree, and that its therapeutic value is not limited to its use as an anæsthetic, is evident from its chemical and physical characteristics. At the same time it combines properties so different from those of oxygen, that the two are by no means therapeutically identical.

Several small volumes have been devoted to this gas, all but one of them, so far as I am informed, limited to a study of its claims as an anæsthetic.

In 1860 Dr. George J. Ziegler, of Philadelphia, issued a little volume, now out of print, in which he claimed much for this gas in the treatment of several forms of chronic disease. Experimenting somewhat extensively, his success led him to assert emphatically that, if properly exhibited in suitable cases, it would be found not only a *materia medica* but also a valuable *materia alimentaria*. Classing its anæsthetic and antispasmodic properties as secondary, he insisted that it served as a *direct source of supply to the blood and tissues*.

Later, some enterprising but unscrupulous pretenders "discovered" in this gas the so-called "oxygenized air," which a dozen years ago was extensively advertised as a cure-all. "Rights" to manufacture and administer it (!) were sold to gullables for a round sum, the process of generating it being bunglingly disguised by the addition of ferric carbonate or other inert coloring material to the ammonium nitrate used. Even to this day a firm in Philadelphia is still harping on the miraculous alchemy of "compound oxygen." What their office remedy may be I do not know; but the trash they send to their mail correspondents, calling it "home treatment," is a barefaced swindle and utterly worthless, being nothing more than a weak solution of the nitrates of lead and ammonium, or of ammonium muriate and St. Croix rum.

The process for evolving nitrogen monoxide is simple and well known to every tyro in chemistry. The gas should be washed through not less than four waters (wash-bottles)—half a dozen would be still better—before it is fit for inhalation.

The *peroxide of hydrogen*, HO_2 , was discovered by Thenard in 1818, but has not until quite recently attracted any attention as a physiological agent. Assmuth and Schmidt made some unsatisfactory experiments with it in 1864. Richardson soon after used a solution of it in water, and approved it for internal administration. Its very unstable nature and disagreeable flavor, however, prevented any degree of popularity, and not until 1878 were any satisfactory experiments conducted. In that year Gutmann and Schwerin demonstrated that it underwent decomposition in the tissues, liberating free oxygen in quantity sufficient, when pushed, to induce gaseous pulmonary embolisms, with arrested capillary circulation, and finally fatal results.

About the same time Stöhr, experimenting with it as a disinfectant, employed it extensively in cases of phagedænic and syphilitic ulcers and diphtheria. According to this author the pus from venereal ulcers lost its virus after two hours contact with a concentrated solution of peroxide of hydrogen. The discharge from ulcers treated with it quickly assumed a more benign character, healthy granulations appeared, and losses of substance were rapidly repaired.

More recently MM. Péan and Baldy have given this agent quite extended trial in the surgical wards of the Hôpital St. Louis (Paris), as a substitute for carbolic acid in antiseptic dressings. Under its use the general sanitary condition of the wards notably improved, cases of traumatic fever and erysipelas became less frequent, and it was found especially desirable as an application in dressing flaps, after amputations, union by first intention being decidedly encouraged by it. As compared with carbolic acid and other antiseptics it possessed the manifest advantage of being devoid of both unpleasant odor and toxic influence, while its application was painless, if not even agreeable.

Following in the wake of these promising and suggestive tests, Dr. Landolt found its use in ophthalmic surgery to be a great advance over that of any known antiseptic, since it can be used of a strength sufficient to effectually destroy all forms of microzoa without injury to the delicate structures to which it is applied in ocular surgery, which is not true of carbolic acid, alcohol, salicylic acid, etc. He also found it to be possessed of very remarkable detergent properties, promptly cleansing suppurating surfaces, arresting septic fermentation, and rapidly checking suppuration in even neglected cases of gonorrhœal ophthalmia.

For more extended details of Dr. Landolt's interesting experience, see the *London Medical Record*, for March, 1883.

At this point, some inquiry as to the *modus operandi* of super-oxidizing agents and the final disposition of the quantity of oxygen daily consumed or *appropriated* in the human system will not be out of place.

A healthy adult, at active exercise in the open air, inspires daily one thousand gallons of oxygen, diluted with four thousand gallons of nitrogen.

Regnault and Riesel have shown that the decarbonization of the blood is one of the minor offices of the oxygen inspired. Of the one thousand gallons daily required, from ten to twenty-five per cent.—one hundred to two hundred and fifty gallons—is *absorbed, directly and in a free state, into the blood* (Magnus).

The marked affinity of the blood for oxygen is indicated by the physical fact that the former readily absorbs two and one-half times as much of the latter as water at the same temperature.

Nor is it true that the carbon dioxide exhaled during animal respiration is wholly formed in the lungs. It already exists in the venous blood before it reaches the lungs, while both carbon dioxide and free oxygen exist in arterial blood (Dalton).

Magnus found the proportion of free oxygen to carbonic acid by volume in arterial blood was as 10 to 25; in venous blood as 10 to 40.

Thus in the pulmonary circulation carbon dioxide is given off and oxygen absorbed, while in the general circulation the oxygen gradually disappears, and is replaced in the venous blood by carbon dioxide. The free oxygen in the general circulation exists there in the form of a simple solution. It is finally absorbed from the blood of the capillary vessels, and *becomes fixed in the substance of the vascular tissues*. The blood is therefore a circulating fluid destined to transport oxygen from the lungs to the tissues, *for it is the tissues themselves which finally appropriate the oxygen and fix it in their substance* (Dalton).

Burdon-Sanderson has further shown that the red blood-cells are the main carriers of oxygen, and that the condition of inflammation, in its earlier stages, essentially consists in a sluggish and finally immobile condition of the white blood-cells, from want of a due and regular supply of oxygen; and that the activity of the white blood-cells is in exact proportion to the amount of oxygen present. This would seem effectually to refute the prevailing impression that an over-supply of oxygen to any part necessarily induces an inflammatory condition.

The principal source of the carbon dioxide of the blood

is the decomposition of the tissues, an essential part of their constant metamorphosis. The experiments of Marchand prove that *even here it is not a process of direct union of oxygen with the carbon of the tissues, but in some other and more indirect mode*.

Further evidence that oxygen and its congeners are important elements in every stage of the process of tissue-building, that oxygen itself is an element *in quo multum alimenti est*, is scarcely necessary. It is evident, however, contrary to the generally accepted ideas, that oxygen should be classed as a *restorative* rather than a *destructive*, and as *contributing directly toward constructive rather than destructive metamorphosis*.

Instead of constantly breaking down tissue by true chemical oxidation, as is almost universally taught and unthinkingly accepted, it really replenishes wasted tissue, both by supplying in itself an essential element toward such repair, and by stimulating and correcting, at every step, the assimilative process.

On the other hand, admitting that the stereotyped assumptions in physiology are true, the rate of metamorphosis is held to be the gauge of vitality. Imperfect or impeded metamorphosis is disease, arrested metamorphosis is death.

In many of our therapeutic efforts of late are we not too eager to hasten *constructive* transformation, almost forgetting that this process must in all cases be both preceded and accompanied by *destructive* action! And do we not ignore the glaring fact that *no molecule of matter, whether of nerve or muscle-fibre, bone element, or blood-plasma, can be made to assume its position in the animal economy except through its direct association with this vital and inevitable element—oxygen!*

Throughout the organic world oxygen in some of its protean forms, is the universal basic element; the addition or elimination of a single equivalent often sufficing to transmute the blandest article of food into the most virulent poison, and *vice versa*.

(To be continued.)

A CASE OF INEBRIETY WITH CRIMINAL IMPULSES.

BY T. D. CROTHERS, M.D.,
HARTFORD, CONN.

THE following case has a peculiar interest, not from its novelty, but as a type of a large class who are best known to criminal lawyers, and whose career is one progressive march of degeneration.

William B.—was placed under my care in 1881, as a periodical inebriate, who at this time was suffering from delusions and delirium in which he heard voices urging him to kill his wife and set fire to the house. He also felt a strong impulse to kill some one at times, particularly when recovering from the effects of spirits. He loved his wife and told her frankly of this state. If he went out in the street he seemed to hear the same voices telling him to do something startling that would create a sensation, and impulses to find an occasion to do so filled his mind. These impulses were pleasing and indulged in, although recognized as foolish vagaries of the brain. He would walk about for hours, living over in his mind scenes of great excitement, such as rescuing some great man from death by a runaway, or saving him from the cars, or from drowning, or a burning building. He would come home all exhausted and tell what he had thought, go to sleep, and hours after wake up with but a faint recollection of it. His parents were inebriates and neurotics, and died in early life. He was brought up by an uncle, and was educated as an inventor and machinist. He was temperate and intensely devoted to his work. Having made several profitable inventions, he became wealthy and married, living well in good surroundings. At thirty-five years of age he began to drink, from the loss of a child by drowning, the result of his carelessness.

Ten years after, from drink, he became a workman in the factory he had once owned. He used spirits to great excess, periodically, and the free interval became shorter steadily. The drink paroxysm came on without any intimation, and would not be realized until he had drank several glasses of spirits; then he would struggle against it, but to no purpose. Usually he would be walking the streets, after his work was over, with no thought of drinking, and only complaining of general exhaustion, when suddenly, without thought, he would enter a saloon and drink. When the spirits began to affect him he realized the danger for the first time. He never drank in company at the beginning. His mind remained about the same until the effect of alcohol passed away, when melancholy and hallucinations appeared. Not only his senses were disturbed, but his reason and judgment suffered, and he fully realized it in the remark "that it seemed like a thick cloud, full of deceptive voices and impulses that he was powerless to disobey, although he knew they were wrong."

The second or third day's removal from alcohol brought relief from these mental conditions, and later the memory of them grew fainter, and only remained as dim shadows of the past, his mind recovered its apparent force, and he seemed to be more anxious to be successful. He spent his leisure in reading and drawing models of new inventions, living very temperately in every respect. If some one should present the subject of temperance in private, or from the lecture stand in his hearing, he would be strangely agitated, and always drink within forty-eight hours. The same result would follow if he should try to help any one who was intoxicated.

A temperance revival in the neighborhood had the same effect of causing him to drink, although he was a shining example of those who were cured by grace. Three years before admittance, for the first time he had an impulse to place obstructions on the railroad, and thus witness an accident. From that time these impulses varied more or less, and from his own statements were often influenced by newspaper accounts of crime and deeds that created a sensation. If, while drinking, he should read of some great sensation, in which one man became very noted, he would revel in the thought, and even speculate how he could do the same. Later, these morbid fancies grew into homicidal impulses, which filled his mind with the greatest alarm, for which he sought every means to drive away. He drank to stupor for this purpose, and then when he recovered drank again as the only means for relief. His recovery under my care was rapid, and all these morbid states faded away. His mind was unusually clear about himself, and except a degree of nervous irritability, and a shrinking from personal contact with any one, he was not to any general observation different from others. Six weeks after admission he awoke one morning depressed, and soon after heard voices and felt impulses to burn up a neighboring church. Then they changed to a plot to blow up all the saloons in the city with dynamite at one time. He was fully aware of the nature of these thoughts, but it afforded him pleasure to go over the details and think of the results of this plot. The next day they faded away, and left but little impress on his mind. Four weeks later, after a period of some excitement concerning a business transaction, a similar plot filled his mind to destroy a drug store whose proprietor was not reputable. This was the last appearance of these morbid states, and after being under treatment eight months, he went away restored. Nearly two years after he was well and temperate, living in a country village, occupying a position of respectability.

These morbid states had not returned, he lived retired and avoided all excitement of every kind.

In all probability this recovery will be more or less permanent, depending on the surroundings and freedom from any great strain or drain.

This case was on the borderland of crime, and would

positively have developed into a homicide or incendiary very soon. In court the only evidence in defence would be periodical inebriety, and possibly the purposeless or motiveless character of the crime. In the prosecution it would appear that the crime was premeditated and performed coolly, and beyond some transient excitement and muscular trembling there was no clear evidence of delirium tremens or alcoholic mania. The mind would appear to be clear, and his statements of voices and impulses to do the act would be considered a mere plea in defence. If the medical expert of criminal courts should be called on to examine the case, looking at his present state and comparing it with the general features of the crime, he would find nothing to indicate legal irresponsibility.

The result would be that all these cases would suffer the full measure of punishment, the practical effect of which is to make criminals and paupers of them ever after.

In this way our courts, from want of study and knowledge of the cases which are brought before them, are cultivating and developing the very conditions which they seek to prevent.

This case would be called alcoholic mania in the early stages, and very largely concealed, because the patient recognized its nature, and was ashamed to acknowledge its presence. These delusions and hallucinations were held in control by a very slender cord, which might break any moment, and pass off like a storm, leaving the mind comparatively free and clear, no matter what had occurred.

It is impossible to estimate the mental capacity of the person who commits crime following or during a paroxysm of drinking from a general study of the character of the crime. In this case the delusion or delirious conception to commit crime was known only to his wife. If he had killed her, no one could have corroborated his statement of a morbid impulse. The fact could only have been brought out by a careful study of his history.

In a case which had been sent repeatedly to jail for drunkenness and assault, it appeared that after a certain period of excess in the use of alcohol most positive delusions of persecutions appeared and readily attached themselves to any one who opposed him, that he assaulted any one on the slightest provocation, with all the characteristics of an insane man; yet the court, lawyers, and medical experts saw nothing but drunken fury, that punishment in jail could best relieve.

In another case an inebriate, after a certain point in the use of spirits, embarked on the most questionable business transaction, lost all consciousness of right and wrong, committed criminal acts of various kinds, was arrested, and the court considered only the nature of the acts, their evident premeditation, and the coolness with which they were committed, and fixed the punishment to the extreme limit of the law. In both of these cases, heredity, and a marked history of physical causation and progressive degeneration extending back for years was noted; but, as in most of the cases of this disorder, it was unknown, not studied, and concealed from general observation. These men had, to all appearance, a full knowledge and control of themselves, and yet they were literally waifs without power and ability to guide or direct their actions.

Alcohol seemed to suspend their self-control, and leave the disordered impulses subject to every wave of influence. Upon this point turns all questions of responsibility, not upon knowledge of right and wrong, and feeling, but upon power of control. This is the teaching of science, above all law, or decisions of courts. The inebriate, or man who uses alcohol to excess, has always a defective organization, either originating before alcohol was used or developed by this poison. In both cases states of physical and psychical degeneration exist, which make it impossible for the mental operations to be carried on normally.

In my studies many cases appear in which these strange, unaccountable criminal impulses are present that do not develop into crime. Why they do not is not known; but it is clear that all the conditions are present. The impulse and disposition, and the details of the act is lived over in the mind of the person, but its literal fulfilment is not consummated. I think future studies will show that these impulses are common, and refer to every state and condition of the mind and body. When they appear in kleptomania or pyromania, or any of the many crimes that are so often associated with inebriety, they are both pathological and psychological.

The methods of cure by legal means, to confine them in the worst mental and physical conditions, and then turn them out less able to become good citizens, less able to live a normal healthy life, is a disgrace to our civilization.

These cases are in our neighborhood and at our fire-sides, and mutely appeal to us for help.

They are victims of physical conditions which physicians only are competent to determine. Courts and moralists are incompetent; they must be studied by scientific men from a physical point; then much of the confusion of the present will clear away.

Progress of Medical Science.

A YOUNG ETHER DRINKER.—A remarkable case of ether drinking is related in the *Gazette des Hôpitaux* of September 15, 1883. The patient when first seen by Dr. Sédan was but ten years of age. He was bright and intelligent, studied hard, and was one of the best scholars in his school. He confessed that he drank ether and said that it was by means of this that he was able to stand at the head of his class. Every means was tried to cure him of the habit, but in vain. He would steal money from his parents, and then go out at night to buy ether in the pharmacies. This was continued for nine years, the daily amounts of ether consumed rising gradually until he drank between one and two pints every day. He never experienced any ill effects beyond the intoxication, and death resulted finally from mitral disease, from which he had suffered for many years.

THE TREATMENT OF ABSCESSSES OF THE NECK.—Dr. John A. Lidell, in a very instructive article on this subject in the number of *The American Journal of the Medical Sciences* for October, 1883, points out that sudden death may occur from deep-seated abscesses of the neck, or the continuance of life may be greatly endangered, much oftener than is generally supposed, and that these abscesses in the neck are more frequently attended with hemorrhages due to the opening of important blood-vessels by ulceration or erosion, and by *ramollissement* consequent upon the disorders themselves, than abscesses in the other surgical regions. The superior liability of cervical abscesses to the spontaneous occurrence of dangerous hemorrhages arises in part from the greater number and importance of the cervical blood-vessels; but more particularly from the inanition and exhaustion, or low state of the constitutional powers, and consequent feebleness of the reparative forces, which rapidly result from most of the deep abscesses of the neck, or rather from the inability to swallow enough food to support life, and from the powerlessness to get any refreshing sleep, or even repose, with which these abscesses are oftentimes attended. The septic or toxæmic influence of the fetid secretions and exudations which present themselves in the oral and faucial cavities in many instances, also aids materially to still further depress the patient, and weaken the reparative processes of his system. These deep-seated abscesses of the neck, when allowed to run their own course, do not exhibit any tendency to a spontaneous cure; but, on the contrary, they

always tend to destroy life by burrowing or spreading, etc.; and Dr. Lidell shows that the earlier they are laid open and evacuated the better for both patient and surgeon. As soon as fluctuation is discerned, the abscess-cavity should, without delay, be freely laid open, the coagula turned out, the bleeding-point, or source of the hemorrhage, brought distinctly into view, and the delinquent vessel itself should be ligatured on each side of the aperture in its walls. But should the ligatures cut through, the actual cautery must be applied to the bleeding point, the primitive carotid artery should be firmly compressed against the cervical vertebræ by the surgeon's thumb or fingers applied on the anterior part of the corresponding side of the neck, between the larynx or trachea and the inner border of the sternocleido-mastoid muscle, with force enough to press the artery backward and inward against these vertebræ, and flatten it thereon. Should this procedure fail, it will be advisable, especially in cases where the bleeding proceeds from tonsillary abscesses, to ligature at once the primitive carotid artery.

HERPES OF MALARIAL ORIGIN.—The following are the conclusions arrived at by Drs. Verneuil and Merklen in a recent memoir: 1. Herpes is one of the frequent manifestations of the paludal poison. 2. The eruption may precede the onset of intermittent fever or occur during any one of the three stages of the attack. It may even show itself after the fever has been subdued by quinine. There is then no etiological correlation between herpes and fever, notwithstanding their frequent coincidence. This proposition is important, maintaining, as it does, that herpes is not a result of the high temperature, but is, like the fever itself, a result of a more general cause, viz., the malarial poison. Hence we find a new class of skin diseases, the *paludides*. 3. Malarial herpes presents no special characteristics. Its most usual seats are the borders of the lips, the edges of the nostrils, and other parts of the face most richly supplied with nerves. 4. The black crusts, or at least the black vesicles of herpes seem to belong to the pernicious forms of malarial fever. 5. In exceptional cases, paludal herpes shows itself in the form of zona. 6. In its most common forms, it may be preceded and accompanied by vaso-motor troubles and disturbances of sensibility of the skin about it. The cause of the eruption seems to reside in a nervous lesion, perhaps in a congestion of the cutaneous nerve-branches, resulting from a localization in these nerves of the paludal poison.—*Journal de Médecine de Bruxelles*, August, 1883.

THE PRURIGO PAPULE.—In the October number of *The American Journal of the Medical Sciences* for the current year, Dr. Morison, of Baltimore, considers that the prurigo papule is formed by an infiltration beginning around the upper layer of vessels of the corium, and that this infiltration extending upward surrounds the papillary vessels, enlarges the papillæ, thus pushing up the epidermis, which becomes thickened at an early stage above them, and at last penetrating it, forms within its layers a small vesicle containing serum, blood, and lymph-cells. The signs of infiltration surrounding the hair-sheaths and sweat-ducts are secondary, and they play no especial part in the process. Their presence in the papule is accidental, and it is certain that the primary changes in the skin are not in connection with them. The color of the papule at first does not differ from the rest of the surrounding skin, on account of the depth of the slight infiltration with which it begins. For the same reason, it is at first only felt, and not seen, as the infiltration has not extended high enough to push up the epidermis perceptibly, but is sufficiently great to give a feeling of knot-like hardness underneath it. He considers the whole process due to an inflammation, and that all the signs of chronic dermatitis follow regularly, according to the length and duration of the disease, and the amount of scratching, which the itching, as a secondary symptom, causes. Clinically the formation of the papule

coincides with this description, for there is always noticed in the beginning of the disease, after careful investigation of the skin, a slight roughness, and a sensation as of running the hand or finger over small knots, covered with an intervening membrane. At this stage there is no itching. In fact, the itching does not begin until the infiltration has so far advanced that the papules are more distinct. If before this occurs the treatment is begun, no itching appears. This proves, as Kaposi says, that all the symptoms of the disease go hand in hand with the increase or decrease of the papules.

SCOTT'S METHOD IN THE TREATMENT OF WHITE SWELLING.—A method of treatment of white swelling, advocated by John Scott in 1828, but afterward fallen into oblivion, was revived by Dr. Suchard, in 1879. The latter begins by rubbing the joint briskly with a sponge or coarse cloth dipped in spirits of camphor so as to produce rubefaction of the skin. Then the part is covered with lint, spread with equal parts of mercurial ointment and soap cerate, over which adhesive plaster is applied in strips as for ulcers of the leg. Over all is molded a leather splint. The dressing is renewed every week or every fortnight, according to circumstances. Dr. Cazin has modified this dressing. He employs friction in the same way as Dr. Suchard, but in place of the mercurial ointment he uses vaseline thickly spread on cotton. Adhesive plaster is then strapped about the knee. Over this he lays another layer of cotton and then applies a silicate of soda bandage. The dressing is reapplied every two weeks. When the bandages are removed, the skin beneath is often the seat of an intense erythema. It is then necessary to wait a few days before reapplying the dressings. This treatment is said to have been followed by surprisingly good results.—*Journal de Médecine de Bruxelles*, August, 1883.

EXCISIONS OF THE TARSUS.—In cases of tarsal disease, amputation through the leg or at the ankle has been and still is regarded by surgeons generally as much to be preferred to any more conservative treatment. Dr. P. S. Conner, of Cincinnati, in the October issue of *The American Journal of the Medical Sciences* for the current year, has collected the reported cases of tarsal excision. The three questions he considers are: 1. Is excision a safe operation, or at least attended with no greater mortality than the alternative amputation? 2. Is it likely to put an end to the disease, or is recurrence of the morbid process in the unremoved bones of the foot to be expected? 3. Will the patient, after recovery from the operation, be left with a serviceable limb? As respects the preservation of life, he finds that excision of the whole tarsus, or of one of its great divisions, is not much, if any, more dangerous than an ankle-joint amputation, and not very much more so than a middle tarsal operation. It has, moreover, the advantage of permitting, if necessary, of the subsequent removal of the foot, which, in the cases tabulated, was performed seven times with but a single resulting death. That the disease is very unlikely to reappear is shown by the fact that in only three cases did such recurrence take place. This fact, however, is not so strange as it may at first seem, as it is in direct accordance with the recognized law that the more thorough the removal of diseased bone the less will be the likelihood of a relighting up of the bone inflammation. By far the most important question of the three proposed is that which has reference to the functional value of the saved foot. He holds that its usefulness is likely to be sufficiently great to warrant the taking of a somewhat increased risk of life, and in subjecting the patient to the necessarily much greater duration of the period of healing—a period that, though it may be as short as four weeks, may occupy more than twice as many months or even half as many years. Of the 108 operations tabulated by Dr. Conner, 10.18 per cent. resulted fatally. Of the 95 cases, the end-results of which are known, 10.53 per cent. were failures; 6.32

per cent. left the subjects of them able to walk with a cane or crutch; in 24.21 per cent. there was, after complete consolidation had taken place, no pain nor tenderness, little or no limp, and the individuals were not prevented by the condition of the foot from earning a livelihood; and in 47.37 per cent. the result was so good that the gait was not a bad one, the support of the body was firm, and locomotion was so easy and perfect that the individuals could, without special fatigue, walk long distances, even twelve to fifteen miles a day.

FATTY STOOLS IN DISEASE OF THE PANCREAS.—Dr. Ziehl records a case of cancer of the pancreas occurring in Professor Erb's clinic at Heidelberg. The case itself presented no unusual features, but the predominance of gastric symptoms suggested the stomach as the seat of the disease, which was marked by the appearance of a painful tumor in the left side of the epigastrium, and by jaundice. The motions were of a peculiar silvery-gray color, and found microscopically to consist in great part of masses of acicular crystals soluble in ether; chemical analysis showing the stools to be composed of fat to the extent of half the solids. On dissection there was found a large scirrhus cancer of the pancreas, which had invaded the walls of the stomach and duodenum, and occluded the common bile-duct. The pancreatic duct was dilated and distended except at its termination, which was lost in the cancerous mass. The writer, after saying that the case illustrates the well-known fact of pancreatic disease being marked by the occurrence of fat in the stools, shows that the form in which the fat occurred in this case was exceptional, almost requiring the microscope for its detection, whereas it usually occurs in amorphous masses recognizable at once, and not in crystalline form. He further shows, by reference to cases recorded by Friedreich, Nothnagel, and Gerhardt, that when fatty crystals in excess are present, there is not only pancreatic disease, but also occlusion of the bile-duct, the last-named author finding crystals resembling tyrosin and leucin in a case of catarrhal icterus.—*The Lancet*, September 22, 1883.

CALCULOUS AND OTHER AFFECTIONS OF THE PANCREATIC DUCTS.—Dr. Johnston, of Washington, D. C., in an elaborate paper in the October (1883) number of *The American Journal of the Medical Sciences*, presents a good clinical study of this subject. Although he has been able to collect only thirty-five cases in which, upon post-mortem examinations, stony concretions were found in the pancreas, he cannot but believe that calculi are present in the pancreas far oftener than is supposed, and he can only attribute the paucity of medical literature upon the subject to the inexperience or carelessness of observers.

OPERATIVE INTERFERENCE IN IRREDUCIBLE DISLOCATIONS.—In a paper on this subject in the *Revue de Chirurgie* of August 10, 1883, Dr. Poincot formulates the following conclusions: 1. In considering the question of operation, dislocations must be divided into three classes, according as they are recent, of short, or of long standing. 2. Direct operative interference in recent luxations should not be attempted, except in dislocations of the ankle and of the thumb, in which division of the tendo-Achillis and of the lateral ligaments respectively may be practised. 3. In luxations of longer standing subcutaneous section is first to be employed. Arthrotomy should be reserved for those cases in which the vicious position of the bone renders the limb useless, or menaces its vitality by pressure on important parts, as in certain dislocations of the shoulder and of the knee, or when the dislocated fingers impair the utility of the hand. 4. In old dislocations, in which subcutaneous section is of no avail, arthrotomy, with or without resection, is necessary in the ginglymoid joints, such as the elbow, knee, ankle, and fingers; for the enarthroidal articulations, as the jaw, the shoulder, and the hip, osteotomy would be preferable.

PULMONARY CONGESTION OF RHEUMATIC ORIGIN.—In the medical section of the Association Française pour l'Avancement des Sciences, Dr. Huchard presented an interesting paper on this subject. Congestion of the lungs may occur during an attack of acute articular rheumatism, and may be generalized, in which case it is often most alarming in its severity, or local, when it is usually unattended with danger. Or, perhaps more frequently, it comes on without any articular symptoms in rheumatic subjects. There are two forms under which the congestion presents itself. In the first, it is acute and may be shifting. This variety may often be accompanied by profuse hemoptysis, preceded by symptoms of pulmonary congestion. But the hyperæmia may not go as far as hemorrhage, and then there are symptoms only of great oppression. Sub-crepitant râles are audible, together with blowing respiration. There is dullness on percussion, and absence of vocal fremitus. Such a state is sometimes incorrectly diagnosed as pleurisy. The second form is stationary and chronic. The congestion may persist for years, finally disappearing entirely upon the advent of articular symptoms. Such cases are very liable to be mistaken for tuberculosis. The hemoptysis, the author thinks, is due to the giving way of portions of the vascular walls in which pathological changes of rheumatic nature have taken place. It is analogous to the rupture of the cerebral vessels in apoplexy. Arthritic hemoptysis, while of much less gravity than that occurring in pulmonary tuberculosis, yet calls for systematic and persevering therapeutical management. M. Huchard recommends the prolonged use of quinine, salicylate of soda in small doses. The arsenical preparations, or the iodides of potassium and of sodium, also in small doses. He also uses intestinal derivatives, such as aloes, leeches to the anus, dry cups, or even phlebotomy.—*La Tribune Médicale*, September 16, 1883.

CLASSIFICATION OF THE PORRO OPERATIONS.—Dr. Robert P. Harris, of Philadelphia, states, in *The American Journal of the Medical Sciences* for October, 1883, that, from a careful examination of the literature of this subject, he finds that we have no less than nine forms of operation, some of them differing very materially from the original, all called by the name of "Porro," and classified together, although having very different rates of mortality. It is hardly necessary to claim that this is very unjust to the originator, and unfair to his operation. If the Porro method is to stand upon its merits, rated by its proportion of cures, we must in justice exclude from the record all the cases not strictly deserving of the title. As it would only complicate matters to make nine orders of cases, Dr. Harris proposes to combine them where this can be fairly done, and thus reduce the list to four classes. 1. True Porro operations; Porro-Müller operations. 2. Puerperal utero-ovarian amputations, with the pedicle dropped in. 3. Premature ablations of the gravid uterus, the fœtus not being viable. 4. Pré-vôt's operation, misnamed "Porro." (Utero-ovarian amputation after laparotomy for rupture of the uterus. Dr. Harris appends a tabular record of 140 cases, from which it appears that the Porro operations, carried out as originally designed, has saved $46\frac{1}{4}\%$ per cent. of the cases; the Porro-Müller method, unmodified, has saved $52\frac{1}{4}\%$ per cent.; and the combined, $48\frac{8}{10}\%$ per cent. of the women, and 90 out of 118 children.

MASSAGE IN THE TREATMENT OF HYPOPYON.—By gentle pressure and light friction over the eyeball through the lower lid, Dr. Just has succeeded in diminishing the purulent collection in the anterior chamber and causing it to become mixed with the aqueous humor. In several cases of hypopyon treated in this way he has seen absorption occur very rapidly. Dr. Hirschberg obtains similar results, when the collection of pus is not fixed, by causing the patient to turn frequently from side to side, changing the position hourly. Dr. Klein has employed enassage also in other affections of the eye, such as

phlyctenular conjunctivitis and diffuse parenchymatous keratitis. It is contra-indicated when it causes pain or provokes a persistent ciliary irritation.—*L'Union Médicale*, August 25, 1883.

CLOSURE OF THE JAWS AND ITS TREATMENT.—Dr. J. Ewing Mears, of Philadelphia, in an able paper in *The American Journal of the Medical Sciences* for October, 1883, discusses the various operations which have been suggested for the relief and cure of permanent closure of the jaws and the objections urged against them. He then narrates a case in which he operated in the following manner: By division of the ramus of the jaw, about its middle, exsection of the condyle and division of the insertion of the temporal muscle, thus releasing the coronoid process and affecting its removal with the condyle—division of the masseter muscle at its points of origin—non-interference with the cicatricial band. By this plan he hoped to secure sufficient space for free movement of the remaining portion of the ramus, and he proposed to utilize the cicatricial band as a *quasi* ligament, and obtain movement of the bone between this band and the internal pterygoid muscle. By division of the masseter at its point of origin, he proposed to relieve the tension of this muscle and more effectually prevent union of the divided fibres. The plan of operation suggested and practised is novel, in the fact that it includes removal of both coronoid and condyloid processes with the upper half of the ramus, as well as division of the masseter, external pterygoid, and temporal muscles, at the point of origin of the former, and the insertion of the latter. The advantages claimed over other methods are: 1. Its application to all forms of permanent closure, that due to temporo-maxillary ankylosis, as well as to cicatricial formations. 2. The utilization of the entire body of the jaw in opening the mouth, not only affording in this way greater advantage in mastication and articulation, but serving to prevent deformity. 3. The formation of a more perfect artificial joint in the removal of both processes, thus overcoming the resistance of the more or less fixed upper segment, when the joint is made either in the body or the ramus of the bone.

PROGNOSIS OF MITRAL STENOSIS.—Dr. Duroziez, writing in *L'Union Médicale*, states that mitral stenosis is not of such grave import, as regards life, as is commonly supposed. It is true it causes more or less acute suffering, but the patients live nevertheless. He records a number of cases of this affection, from a study of which he draws the following conclusions: 1. Mitral stenosis, simple or combined with other valvular lesions, permits in exceptional cases, life to pass the sixtieth year. 2. The complication of mitral regurgitation does not aggravate the prognosis. 3. The coexistence of aortic insufficiency renders it more grave. 4. The complication of a tricuspid lesion is of very serious import.

DELIVERY OF HYDATID MOLES BY EXPRESSION.—Dr. Gregoric advocates a new method for the treatment of hydatid moles (*Allgemeine Wiener Medizinische Zeitung*, August 21, 1883). When the diagnosis is definitely made, uterine contractions should be induced by a vaginal tampon and subcutaneous injections of ergotine. Then, as soon as the os is dilated for about an inch, the contents of the womb are to be forced out by Credé's method. This need not be done rapidly, but may be practised repeatedly at short intervals. The mole is squeezed out through the vagina, as the author expresses it, like a sausage. The uterus quickly contracts, and the hemorrhage ceases.

JEQUIRITY IN GRANULAR LIDS.—Drs. Parisotti and Galezowski have not met with the success in the employment of jequirity that other oculists have obtained. The local trouble was not aggravated, neither was it in the slightest degree benefited. But an intense febrile reaction followed the application and continued for over ten days, while the immediate effect of the jequirity was to cause great suffering.—*Recueil d'Ophthalmologie*, August, 1883.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, October 27, 1883.

NEW METHODS OF TREATING WOUNDS.

THE ingenuity of German surgeons has been much exercised within the last two or three years in order to devise some new method of dressing wounds. It is now nearly two years since carbolic acid and the Lister dressing began to be superseded in many hospitals by the use of iodoform. The latter drug was so enthusiastically adopted that its introduction into general surgery was thought to constitute an epoch in modern surgery. It was soon found, however, that many other substances would answer as well or better. In 1880-1 Kocher began to recommend his bismuth dressing. He used the subnitrate of bismuth suspended in water in a strength of one per cent. The wound was covered with this and over it a dressing of gauze and rubber was applied somewhat like that of Lister. Remarkably good results were reported by himself as well as by Langenbeck and some others. In a few cases, however, it was stated that a gangrenous stomatitis was excited, and it is known that if the amount of bismuth (subnitrate) be excessive, symptoms resembling lead poisoning develop.

In September, 1881, Esmarch began to use at his clinic an iodoform dressing covered with bags of dried turf-mold. Neuber reported excellent results from this.

In 1882, Fischer of Strasbourg, recommended the use of naphtholin as a substitute for carbolic acid and thymol.

For a considerable time, oxygenated water has been used by MM. Pean, Paul Bert, and Brochin, in the wards of the Paris hospitals. It continues to be used in some special classes of diseases, as those of the eye.

After Koch's experiments which demonstrated the superior power of corrosive sublimate as a germicide, its use in surgery was taken up. Kummell formulated a method of applying it in the treatment of wounds which goes by his name, and which has been very generally adopted.

Kummell's dressings consist of sublimated gauze and cotton, sublimated silk, sublimated catgut, sublimated oil, and sublimated inorganic dressing materials. These latter comprise powdered glass, sand, coal ashes, asbestos, lint made from spun glass, and, for purposes of drainage, capillary threads of spun glass. Sublimated gauze and cotton are designed to take the place of carbolic gauze and cotton. They are made hygroscopic in the usual manner, and then impregnated with the following: cor-

rosive sublimate, 10 parts; alcohol, 4,490 parts; glycerine, 500 parts.

Bruns, of Tübingen, has recommended the use of wood wool. This consists of finely ground wood, such as is used in the manufacture of paper. It is clean looking, delicate fibred, soft, yellowish-white, having an odor of fresh wood, and absorbs immensely.

The wood-wool possessing the highest absorbent properties is obtained from the *Pinus picea*. It is passed through a sieve, dried, and impregnated with a solution of half per cent. of sublimate and ten per cent. of glycerine. It is extraordinarily cheap. It is exceedingly elastic even in thin layers, so that bandages can be put on more lightly with this than with any other dressing. It takes up twelve times its weight of water.

Dr. Bruns claims that high absorbent qualities in surgical dressings are of vast importance, "as primary wound healing takes place the more readily the more completely the discharges are conducted from the wound—the dryer the wound and its vicinity are kept—as it is under these circumstances that decomposition processes are most securely excluded. If the dressing has absorbed the secretions of the first few days, the evaporation and drying up of the contained moisture should be permitted; then, as the discharge from the wound diminishes, the dressing, now dry, can remain a considerable time as a permanent one. With this object in view, it is indispensable to omit the occlusive layer of the typical Listerian dressing, as the drying of the dressing is prevented by it. With the same object in view he prefers the covering of the wound with glass-wool in place of the protective, as under this the suture line is of necessity kept moist.

In his own clinic the mode of dressing, according to the *Medical Times and Gazette*, is exceedingly simple. After the wound has been disinfected by copious irrigation with a one per cent. (.1 per cent.?) solution of sublimate, and the drainage-tubes have been placed in, the suture line is covered with a layer of glass-wool. Upon this is placed a sufficient quantity of wood-wool either simply wrapped in sublimate gauze or sewn up in the form of a pillow. The latter form is preferred for hospital use. He considers it best then, first to place on the wound a small pillow, then a larger one that will widely overlap this in all directions. These are to be fastened on with a firm binder.

In addition to the above methods others have been devised for the treatment of minor wounds. Powdered sugar, which is aseptic, is recommended by several German surgeons.

We venture to say that it makes little difference in the vast majority of cases which antiseptic or aseptic method is used, provided there be cleanliness, free drainage, and pressure properly applied.

RESECTION OF THE STOMACH AND THE GASTROSCOPE.

PROFESSOR J. MIKULICZ, of Krakaw, has written a series of articles in the *Wiener Medicinische Wochenschrift*, giving an account of a successful case of stomach resection performed by himself, and of the utility of the gastroscope in connection with these operations. There had been, up to July, 32 cases of stomach resection reported. Among these, there were 26 deaths and 8 recov-

eries, giving a per cent. of recoveries of twenty-five. Three of the cases were operated upon for gastric ulcer with stenosis, and of the three, two recovered. There were, therefore, 29 cases of cancer of the stomach, with 5 recoveries, from the operation. Of the 24 fatal cases, the cause of death in 15 was collapse, in 1, inanition, in 5, peritonitis. In the opinion of Mikulicz, the death of the last six by inanition and peritonitis, was due either to deficient skill in operating, or to conditions which, at present, our better knowledge can prevent. As for the deaths by collapse, there is hardly an operation in surgery which has had relatively so many victims from this cause. The explanation lies not only in the length, character, and severity of the operation, but especially in the fact that the patients are generally already weakened by the disease.

There is no operation in surgery which has had its technique and, we might say, indications so well defined in so short a time. It is now generally admitted that the operation is justifiable, but only in the most carefully selected cases. The diagnosis must be exactly made, the growth must be still small, the disease in a comparatively early stage, and the patient not greatly weakened or marasmic.

It is in the hope of its assisting to a more exact diagnosis that Mikulicz recommends the gastroscope. He has examined a number of healthy and carcinomatous stomachs with this instrument. In the healthy stomachs, the pylorus appears like a longitudinal split, or like a star-shaped, oval or circular opening, which is surrounded by a thick wall of red mucous membrane. The muscular wall is constantly in motion. In cases of cancer, the thick protuberance about the pylorus is either entirely absent, or is thrown up in small folds. The powerful muscular action of the pylorus is absent. The gastroscope is evidently not yet a great help in the matter of diagnosis, but further observation and use may make it more so.

THE HOT SPRINGS OF ARKANSAS.

So far as we can learn of the actual facts regarding Hot Springs therapeutics, it is the most empirical of all health-resorts. Very little careful study of their action has been made. At the same time it is a place which is very widely known, and very frequently used.

Hot Springs is a city of five thousand inhabitants, of which nine-tenths is a floating sick population. It lies in a valley between two mountains, along the sides of which there are now seventy-one springs.

The sick population is a heterogeneous one. The patients come from all parts of the country. Those that predominate, says Dr. J. C. McMeehan, in an article upon the Hot Springs published in the *Cincinnati Lancet and Clinic* are those "affected with syphilis, rheumatism, and nervous diseases. All kinds, however, are met with. Women broken down in health from fashionable dissipation, late hours, balls, champagne, and from the effects of sacrificing at the altar of Venus, come here for quietude, rest, pure air, and the benefits derived from bathing. Men broken down from the excessive use of alcoholic drinks and the morphine habit find relief at this place, and under the pleasing and stimulating effect of the waters are able to give up the habits of drinking and opium eating."

An atmosphere of charlatanry seems to hang about the place. This is shown first in the current belief that the waters have great electrical properties. Many of the springs are named after some supposed predominant constituent in them. Thus, there is an Arsenic Spring, which for several years was peculiarly useful in the treatment of skin diseases, until it was found that it contained no arsenic. Another spring, called the Alkaline Spring, is thought of especial value for alopecia, and bald-headed people soak their bare pates for hours in its delusive waters. Another spring is particularly adapted to corns and bunions, while various others have special reputations for the cure of disease. No attempt seems to be made to classify the springs therapeutically upon any other than an imaginative basis.

The water varies in temperature from 93° to 157° F., and the various springs discharge a total of over half a million gallons of water daily.

That this water contains any specially valuable medicinal properties, apart from its heat, seems at present to be improbable. An analysis made by Professor D. D. Owen, as quoted by Dr. McMeehan, gave the following:

	Gramme.
Organic matter combined with some moisture . . .	1.16
Silica with some sulphate of lime, not dissolved by water	1.40
Bicarbonate of lime	2.40
Bicarbonate of magnesia	0.50
Chloride of potassium	0.04
Chloride of sodium	0.218
Oxide of iron and a little alumina	0.133
Sulphate of lime dissolved by water	0.320
Loss. Iodine. Bromine	0.053
Total	6.222

This analysis does not include any of the gaseous or volatile constituents which it is claimed are present; neither does it include the electricity—an agent whose presence always appeals helpfully to the lay mind.

Dr. McMeehan believes, as the result of his experiments, that there is a compound of silicon present. He also asserts that the galvanometer indicates the presence of more electricity than is usually to be found in hot water, and the same observer claims some peculiar physical properties for the water. The experiments are not recorded with sufficient carefulness and detail, however, to warrant any inference from them.

The effects of a continued use of these baths are, says Dr. M., remarkably great alterative action, correcting retrograde metamorphosis; equalizing and moderating nervous excitability; increased action of the absorbent system; increased disintegration of tissue; increase of assimilation and reparation; activity of all the excretory organs, eliminating mineral blood poisons rapidly, such as lead, mercury, and iodine, so rapidly that compounds of the two last named are here frequently prescribed, and are often taken in heroic doses with almost perfect impunity; eliminating also the effete and poisonous products of the disintegration of tissue, by the kidneys and skin, and producing some abatement of the morbid craving for alcohol and tobacco in those who have acquired the habit of the excessive use of these stimulants.

The pathological conditions in which these waters are

contra-indicated, according to the same authority, are : Whenever the pulse is materially accelerated by the disease ; an exalted action of the heart and arteries ; where there is a tendency to active inflammation or any form of acute disease ; where the action of the heart is in any way interfered with, either by structural change or the presence of liquid in the pericardium : where there is a marked increase of the temperature of the body : in hectic fever ; in cancer, or in any form of epithelioma ; where there is a tendency to wasting hemorrhages, and with pregnant females.

There is no doubt whatever that many persons are benefited by a residence at Hot Springs. They seem to be particularly attractive to the venereal. The cause of this is formulated very rationally by the gentleman whom we have quoted. The change in mode of life, the removal from annoying cares to a healthy, well-regulated resort, the powerful stimulating, diaphoretic and diuretic action of the waters are all potent factors. No doubt the high reputation which the springs have got, and the impalpable electrical agencies supposed to exist in the waters also act effectively upon the patients' imagination.

MULTIPLE SMALL ABSCESES OF THE LIVER.

AMONG the greater difficulties with which the diagnostician has to contend, few are more perplexing than irregular pyrexia, more especially when due to an unknown cause, or when the concomitant symptoms simulate those of distinct affections.

So much has been added to our knowledge of abscess of the liver—local parenchymatous hepatitis—by Murchison, Frerichs, Sir Joseph Fayrer, and others, that, as a rule, there is no very great difficulty in establishing a diagnosis, more especially since the introduction of aspiration. The case is somewhat different, however, with multiple small abscesses. The descriptions of cases heretofore noticed have been far from clear, and the negative results which may be gained by aspiration render the diagnosis extremely difficult. The paper by Dr. R. E. Carrington, therefore ("Guy's Hosp. Reports," vol. xli., 1882), in which the clinical histories and post-mortem appearances of thirteen cases are given, is a valuable addition to our knowledge of the subject.

So far as can be judged from the history of the cases after coming under observation, the duration of this affection is extremely variable. Cases may terminate in death in twenty days or less, or they may run on for two or even six months. There is nothing particularly striking in the clinical histories, and it is only by a grouping together of many symptoms that we can diagnose the affection by exclusion. When brought into the presence of a patient suffering with this disease, we immediately notice that he appears to be extremely ill. The eyes are sunken, though they may retain their brightness, the body is more or less emaciated, and the general aspect is that of apathy and drowsiness. Not infrequently the *facies Hippocratica* is seen, and this, with the drawn-up position of the lower limbs and usual dorsal decubitus, indicates the abdominal pain from a local or general peritonitis. The skin, until the fifth or eighth day, is generally hot and dry. After this time, or before in a few cases, profuse diaphoresis comes on, chiefly remarka-

ble for irregularity. The tongue is dry and coated with a brown fur, sometimes creamy at the onset. The dorsum of the tongue may be brown while the edges are pale or red, and sordes collect on the teeth. Abdominal distention, occurring with ascites, a general peritonitis, or local peritonitis about the liver with rigid recti, is an almost constant symptom. The respiration is thoracic, as would be expected, may reach 38 or 44, and the breath is sometimes sweetish. Though not a constant symptom we generally find enlargement of the liver, which progressively increases. With the enlargement of the liver, the thoracic respiration, and the peritonitis, local or general, there is, except in rare cases, abdominal tenderness or positive pain, especially in the hepatic region, auscultation showing the peritoneal rub, evincing inflammation over the hepatic surface. Percussion may cause intense pain over the whole hepatic region. Sometimes there is a throbbing pain across the front of the lower part of the chest, continuing for hours, or the pain may be of the sharp cutting nature common to local peritonitis.

Vomiting is not a constant symptom ; it is present in about one-half of the cases. The vomitæ may consist of blood or blood-stained fluid, giving bile reaction, and are intensely bitter. If the blood comes up in clots we are safe in diagnosing a concomitant gastric or duodenal ulcer. Diarrhea and constipation may be said to be equally frequent and are connected with obvious causes, as dysentery, gastric ulcer, and peritonitis. When diarrhoea with pea-soup stools occurs, it is due to an ulcerative process of the bowel, generally in the region of the cæcum. Rigors may or may not be present ; they are by no means constant. Jaundice is present in about one-third of the cases ; it varies in intensity but is general, the urine containing bile-pigment, and, where the liver substance is extensively involved, contains leucin and tyrosin with diminution of urea (one case, however, is reported in which there was an excess of urea). Albumen and sugar may be entirely absent, or there may be a large amount of one or the other. The specific gravity varies between 1.020 and 1.025, and the color may be described as that of porter or strong tea, though it may be normal. Where there is much bile pigment we should expect acicular or violet-colored crystals. Inability to pass the urine is quite a common symptom. The temperature may be described as irregularly febrile. In the same case it may run as high as 106° or 106.5°, and may then, in a comparatively short space of time, become subnormal. In the cases reported by Dr. Carrington the evening temperature rarely went below that of the morning. At the moment of death the thermometer has noted 111° Fahr. in the rectum. The pulse is weak—very feeble in some cases—and compressible. It not uncommonly runs as high as 125 to 135 and may even reach 175 and higher.

From the above description it is seen how inconstant are the symptoms, and, consequently, how difficult the diagnosis must almost necessarily be. With regard to constancy and importance, the febrile temperature may be placed first. Even this, however, is not an invariable symptom, for Murchison has recorded a case of multiple pyæmic abscess of the liver without pyrexia. But with a febrile temperature, our attention is naturally directed either to the thoracic or abdominal cavity, in these cases more especially to the latter, when we consider the aspect

of the patient, the abdominal pain and tenderness, and the hepatic enlargement, with the peritoneal "rub," the emaciation, the apathy, and the dry brown tongue. These are the most constant and important symptoms. As a matter of course, a previous history of an affection which is recognized as a factor in suppurative hepatitis is an important point, but, unfortunately, it is not always to be had.

The pathology of this affection is interesting. The liver is studded with numerous small abscesses, which, on section, pour forth a quantity of pus mixed with bile. The portal veins are found to be extremely distended throughout in many cases, being in a state of intense suppurative inflammation, and contain pus. Section through the portal vessels shows a purulent fluid running from the vein. The venous walls are thickened and soft, and, in parts, detached from the surrounding hepatic tissue. With the exception of cases commencing in an obstructive inflammation of the hepatic ducts, the pus-point is always in a radicle of the portal vein. In some cases the portal and splenic veins are plugged by pus and emboli. Save the exceptions above noted the hepatic ducts are not the principal or primary seat of the disease, for though the smaller ducts may contain pus the main branches are unaffected, and their walls present no appearance of inflammatory exudation. Although the tubes may contain a yellow tenacious material, they are not all distended, and the distention of the smaller ducts is, therefore, secondary. In parts the suppuration may extend as far as the capillaries and secreting system, and a section shows the lobules distinctly marked out, they being of a dull yellow color, with the hepatic vein visible as a red spot in the centre. We may infer that the inflammation has been primarily in Glisson's capsule and the tubes afterward involved. It is to be regretted that no examination was made in these cases for pyemic micrococci, as their presence or absence might throw much light on the subject.

ABSCESSSES OF THE NECK CAUSING SUDDEN DEATH.

THE last contribution to our literature from the pen of the lamented Lidell is not the least instructive of his many interesting papers. In the *American Journal of the Medical Sciences* for October, 1883, is an article showing that certain abscesses of the neck, apparently of but little surgical importance, may cause sudden death from hemorrhage or asphyxia. While these cases are not common, they do occasionally occur, and, as is seen from Dr. Lidell's paper, are more than likely to cause very troublesome symptoms and death, if not promptly dealt with.

A most important feature of these abscesses, as regards prognosis, is their tendency to burrow in the connective tissue of the neck, especially downward (as in a case reported), causing inflammation or compression of the recurrent laryngeal nerves, inflammation and adhesions at the apex of the lung, even pulmonary engorgement and pneumonia, death taking place from asphyxia. The dyspnoea and subsequent asphyxia may be due to œdema of the glottis, caused by inflammation of the adjacent tissue. This œdema glottidis may manifest itself even one or two days after the discharge of

the abscess. Added to this there is danger from opening of the œsophagus or trachea by the inflammation and erosion, or the abscess may discharge itself into the pleural cavity, or mediastinum.

No less important, from a prognostic point of view, is the tendency, in some cases, to erosion of the cervical blood-vessels, and death from hemorrhage. The walls of vessels may become so softened and weakened by the inflammatory process, that, when the external support is removed by the evacuation of the pus, they immediately give way to the blood-pressure. In cases of hemorrhage from this cause it is difficult to determine its exact source. It may come from a branch of the external carotid or from the trunk of the internal, or several arteries may be involved at the same time. Finally, such an amount of dysphagia may be produced as to lead to death from starvation.

As regards the treatment of these deep-seated abscesses of the neck, it should first be remembered that they rarely tend to spontaneous cure. If left to themselves or treated expectantly, their tendency is to burrow and cause the destructive results already mentioned. They should, therefore, be laid open as early as possible, wheresoever they may form. In opening them, he would be a rash surgeon who would follow the general directions for opening abscesses, and plunge the lancet down to the seat of pus. The cervical structures are too important for any such procedure as this. If convenient or possible, the patient should be anesthetized, and a most careful dissection of the superjacent tissues be made down to the pus. As regards after-dressings, these cases call for drainage-tubes and antiseptics. Where hemorrhage occurs, the bleeding vessel should be found and ligated on either side of the bleeding portion. If the vessel walls are so softened as that the ligature cuts through, the actual cautery should be used, but never styptics. It may be that the abscess cavity cannot be laid open so as to bring the delinquent vessel into view. In these cases the common carotid should be firmly and continuously compressed against the cervical vertebrae so as to allow coagula to form and plug the bleeding point. Should this procedure fail, the external, preferably the common carotid, should be ligated. The latter, because as before stated, cannot always be determined, whether the hemorrhage comes from the internal carotid or from some branch of the external. By the timely performance of this operation considerable reputation may be gained and a life saved.

CHLOROFORM NARCOSIS DURING SLEEP.

FOR some time past considerable discussion has taken place through the columns of *THE RECORD* relative to the possibility of producing chloroform narcosis during sleep. In the article by Dr. John H. Girdner (vol. xxiii., p. 457), he reports five cases, in each of which he found it impossible to induce a chloroform sleep without first causing a prior interval of consciousness, marked by sudden awakening, with resistance, etc. In all of these cases the drug was administered from a towel and at a distance of eight inches from the face; in every instance, also, in the same manner and without the slightest variation. Viewed in this light, possibly the results were

not in the main remarkable. Therefore, perhaps, it is not at all surprising that some of our readers, while submitting certain cases flatly opposed in their results to those of Dr. G., should suggest that the drug be held at a greater distance, that the extreme liability to reflex disturbance be carefully avoided, and the approach made more gradually, instead of maintaining a specified distance of eight inches; also, that a certain variation in its quantity and mode of administration be practised. Still, from "the large experience in the administration of anesthetics" which Dr. G. has had, and from the fact that in his experiments "every possible precaution was taken that no error should creep into the result," a certain amount of presumption would appear to lurk in outside advice; on the contrary, nevertheless, we are glad to note that the gentleman mentioned (in a second article which we publish elsewhere) has availed himself of the suggestions offered, and evidently in the spirit with which they were intended. In the article referred to, eighteen additional cases are recorded, all unsuccessful. Of these latter cases, while some of them undoubtedly show positive results, yet others are open to criticism. It would also be interesting to know in what number of instances, while securing these eighteen, the attempt was attended with success.

Moreover, although it has been stated that the testimony of medical experts is anything but conclusive, yet perhaps we might accredit these gentlemen with a slight amount of judgment and discrimination. And while some of our correspondents have seen fit to take issue with Dr. G., especially relative to the final clause of his paper, still we believe, however broad the assertion referred to may appear at first sight, that the medical profession of America is of sufficient number to leave no doubt as to the plain truth contained in it.

In reviewing the several cases which have come to our notice, a few of which have appeared in previous issues, we give a short *résumé*:

In Dr. Murill's case the desired result was secured, apparently with the greatest ease. He omits, however, to state the method of administration, as well as the distance and approach. Dr. Borcheim, formerly house-physician at Mt. Sinai Hospital, mentions numerous instances in which narcosis from chloroform during sleep has been produced by him, while resident at the above institution, and likewise without the slightest difficulty. In Dr. May's case a similar success followed upon the careful and gradual administration of the drug. In Dr. Morgan's patient the first attempt was quite satisfactory, but on a subsequent occasion this was not so marked. Dr. Nelson found some slight restlessness precede the narcotism. This condition passed off, however, on removing the towel somewhat farther, and then upon gradually bringing it nearer the face complete narcosis followed. Finally, Dr. Halderman mentions three cases, the subjects of which were convicts in the Ohio State Penitentiary. Of these two were completely successful. The patient was then roughly handled and otherwise tested, so as to admit of no doubt as to the result. In these cases the chloroform was given from a handkerchief, and, at first, from a distance of two feet.

With the exception of Dr. Halderman's, all the cases above cited were children.

It would appear, therefore, from the foregoing and from other accumulated evidence, that it is quite possible to bring a sleeping patient profoundly under the influence of chloroform, without first causing a period of consciousness. This is more especially true of children. In adults, chloroform narcosis during sleep is, apparently, not so easy, and in many instances it probably cannot be accomplished at all. But that in certain cases it is possible, particularly where careful judgment and skill is exercised in the administration of the drug, we think there can be no doubt. To be successful, however, it is necessary that the means employed, the quantity used, etc., should be selected with excellent judgment, and the drug given by an experienced physician, with great care and by easy and gradual approaches. But that even this plan faithfully carried out will not succeed in all cases is equally evident. In this light, however, we cannot help thinking that the possibility of this procedure would be more practically conclusive were all the successful attempts recorded side by side with the failures.

THE ELECTION AT THE COUNTY SOCIETY OF NEW YORK, AND WHAT CAME OF IT.

THE result of the recent election of officers of the Medical Society of the County of New York for the ensuing year, is quite significant of the sentiment in the medical profession of this city and county, concerning the New Code. The attendance was unprecedentedly large. Never before in the history of the Society had so many assembled on the occasion of an annual election. The reason was well understood by all present. The issue did not rest on a mere choice of the individual gentlemen nominated, for they were all thoroughly representative and beyond reproach. But each ticket was openly nominated as representing one or other side of the Code question. There was the Old Code ticket, composed of gentlemen committed to a repeal of the recent action of the State Society, and the New Code ticket, supporting such action. Each party selected its strongest men, Thomas heading the ticket of the Old Code advocates, and Van der Poel representing the liberals. In fact, the tickets were so arranged as to leave little, if any, chance for purely personal preferences for candidates. The election was to be an expression of opinion regarding the principles which each ticket advocated. And so it is generally conceded by all who took part in the contest. The New Code ticket was elected by an unquestioned majority in a perfectly fair election, and as the result of the largest vote ever polled in this or any other County Society. It is quite probable that the question will remain settled with the County Society for a long time to come. At least it shows the relative strength of the two parties in a very decided manner.

Now, certainly the time seems to have arrived for dropping the discussion of the Code question. There has been altogether too much acrimony infused in the expression of individual views on both sides. Each gentleman is entitled to his own opinions and beliefs. But that is no good reason why there should be so many volunteer missionaries on both sides who should deem it their duty to preach to the benighted heathen.

We have enough of honest men on both sides to save the profession, no matter how the Code question may

be settled. There are enough of medical men good and true who, acting according to the dictates of their consciences, can take care of the fair fame of scientific medicine whether they govern themselves by Old Code, New Code, or no code. We have more trust in the men themselves than in any laws that can be made for them. There is a common platform upon which all can meet. The well-educated professional gentlemen need not be told where it is. There is no law which, of itself, can make a bad man do right, or a good man do wrong. The triumph of the New Code shows that medical men are growing more liberal as to interpretations of professional conduct, and that of itself is a good sign. But the most liberal man among the New Coders cannot abuse his privileges if he is made of the right material, is and just to himself, to his patients, and his profession. It is the man after all. If the doctor, Old Code, New Code, or no code, is not a man, all the voting, one side or the other, does no good. It is perfectly proper to wish that the right sort of man should be as free as possible to do what he believes to be just. There is certainly no harm in that; and from such a standpoint the result of the election on Monday evening may be viewed with becoming satisfaction.

SANITARY INSPECTION OF SCHOOLS.

WE are glad to learn that the energetic President of the Board of Health is taking the proper steps for a sanitary inspection of the different public school buildings in the metropolitan districts. Such an inspection, which we doubt not will be carried on in a thorough and systematic manner, is very much needed. We shall be prepared for all sorts of developments regarding defective plumbing, bad ventilation, deficient light, and improper heating appliances.

General Shaler, in his communication to Sanitary Superintendent Day, asks as an initiative to his movement that a consolidated report of the school-house inspectors recently made be forwarded, and that the sanitary inspectors be directed to continue such inspections, embracing every school-house, including those of the parochial schools in the city.

As soon as inspections of a district are completed a synopsis of them is to be made, showing which are found in a satisfactory condition and which defective, and the character of the defects.

The sanitary inspectors are also requested to make frequent visits to the school-houses within their respective districts as a part of their regular duties, with a view of detecting any neglect of the sanitary rules in reference to the case of the sinks and closets.

We shall be glad to note the progress of this good work.

ANOTHER PRIZE FOR SCIENTIFIC WORK.—A prize, established in accordance with the wishes of the late Signor Bufalini, Minister of Public Instruction in Italy, of the value of 5,000 francs, and to be known as the Bufalini Prize, has been announced for international competition. The subject for 1883-84 is, "The Application of the Experimental Methods to Science." The essays must be received by the Secretary of the Medical Faculty of Florence before October, 1884.

News of the Week.

SIR WILLIAM MAC CORMAC, the distinguished surgeon to St. Thomas' Hospital, London, during his visit in this city the past week, has been the recipient of many courtesies from the leading men of the profession. Numerous private dinners have been given to him, and altogether he has had the freedom of medical New York. On Thursday evening a brilliant reception was tendered him by Drs. J. Marion and Harry Marion Sims, at which a large number of representative men from this city and elsewhere were present. Nor has he been here merely for sight-seeing. During his short stay with us he has delivered two lectures upon surgical subjects which were models of their sort, and were appreciated accordingly by the large audiences which assembled to hear him. Sir William sails for his home to-day and carries with him the best wishes of his many friends in this city, Philadelphia, Boston, and Washington.

PRIZES AWARDED BY THE INTERNATIONAL COMMITTEE OF THE RED CROSS.—The Society of the Red Cross has awarded, through its Committee, the following prizes:

First.—A prize of 2,000 francs for the best essay on "Improvised Methods of Treating the Wounded and Sick," awarded to Dr. Port, of Munich.

Second.—A prize of 2,000 francs for the best essay on the "Improvising Means of Transporting the Sick and Wounded," awarded to Dr. Port, of Munich. These essays are to be published.

The prize offered for the best essay on the Improvising Isolation Hospitals was not awarded.

GAILLARD'S MEDICAL JOURNAL comes to us in its monthly form again and presents a most attractive appearance.

THE PHILADELPHIA COUNTY MEDICAL SOCIETY at its last business meeting again rejected women candidates for membership.

THE BRAIN OF CAREY, THE INFORMER, has been weighed by the district medical officer, at Port Edward, Dr. Ensor. Its weight was sixty-three ounces, "the mass lying in the cerebellum!"

This is just the weight of Dr. Abercrombie's brain, and it exceeds the average by about fourteen ounces.

BLACK-MAILING A PHYSICIAN.—The papers relate a curious story regarding an attempt to rob Dr. George A. Gordon, a prominent and wealthy physician of Sandusky, O. He was one day last week summoned by telephone to call upon a sick person at a house in the suburbs. The doctor drove at once to the house, and was politely ushered in by a man in his shirt sleeves. The door was quickly closed, and the man instantly seized the doctor by the throat and held a "billy" menacingly above his head and demanded his money. The doctor only had \$10 about him, and offered that to the man, but the latter refused it and compelled the doctor to give him a check for \$500 and an order on Mrs. Gordon for a similar sum. The man then tied the doctor's hands, locked him in the house, took the doctor's horse and buggy, and drove away.

The doctor managed to free his hands, leaped from the window, ran to a store near by and telephoned his wife

not to pay the order, and to summon the police to arrest the man if he presented it. The fellow drove to the doctor's house, but seeing the police hurriedly approaching the residence he turned and drove rapidly into the country. He was subsequently apprehended and found to be a homeopathic physician who had graduated from the Cleveland College about five years ago.

THE HOSPITAL SUNDAY COLLECTIONS.—The Saturday and Sunday Hospital Association of this city held a meeting, last week, at St. Luke's Hospital, preparatory to the annual hospital collection for 1883. A report made by the Executive Committee indicates that the association has made large extension in its field of activity, and that the collection to be taken in the different churches and synagogues of the city on the last Sunday of the present year, on behalf of the city hospitals, will be by far the largest in the history of the association. Last year's collection fell somewhat short of the amount realized the two years previous, and this fact brought to the association a conviction that the work required more systematic efforts than it had previously received. There are about 350 Protestant churches, chapels, and missions in New York, together with about 30 synagogues. Of this number, only 97, most of them being Episcopalian, Presbyterian, and Reformed Dutch, contributed last year. This year nearly every minister in the city has received a call from a gentleman duly authorized to represent the association, and by this method of personal appeal all the denominations have been brought heartily into the work, and the canvass now approaching a close indicates that there is a probability that the number of contributing churches on Hospital Sunday the present year will be nearly trebled, 275 churches being already pledged to make contributions. Besides those given above as fully pledged to a collection, about 25 churches are on the list as having given provisional promises, and as there are still a score of churches whose pastors have not been visited, and hence constitute promising recruiting material, the association seems justified in indulging the hope that it will be able to report at the close of the collection for 1883 that on Hospital Sunday the sick poor of the city were remembered by 300 Christian and Jewish congregations. It was reported that in addition to the churches that sent their contributions to the treasurer of the association, 23 churches sent their collections directly to the treasurers of various hospitals.

THE SOCIETY OF GERMAN NATURALISTS AND PHYSICIANS met September 17th, 18th, and 19th, at Freiburg. About six hundred members and visitors were present, a smaller number than was expected. The medical work, so far as is yet reported, was not very extensive. Professor Liebermeister delivered a long address upon "Recent Work in and Contributions to Therapeutics." The address was mainly a review. In the Section for Internal Medicine, Weil, of Heidelberg, described a hereditary form of diabetes insipidus. Among ninety-one members of a family, of whom seventy were alive, twenty-three had diabetes insipidus. Rumpf, of Bonn, stated that the narcotics chloral and morphine, as well as to a less extent chloroform, ether, and alcohol, produced lowering of bodily temperature, which he found to be due to a lessened consumption of oxygen.

In the Section for Pædiatry, Demme, of Berne, presented evidence of the infection of children with tuberculosis by cows' milk. In the Section for Military Medicine, a discussion on the best form of dressing for wounds took place. Maas contended for sublimate dressings, Küster for iodoform dressings. Considerable material was presented in the Sections on Surgery, Gynecology, Laryngology, and Psychiatry.

YELLOW FEVER.—The reported appearance of yellow fever at Brewton, Ala., has been investigated by direction of Surgeon-General Hamilton, who ordered Acting-Assistant-Surgeon Stone (stationed at Savannah), to make a report upon the subject after a thorough examination. Dr. Stone telegraphed that the disease prevailing at Brewton is yellow fever and that 34 cases with 18 deaths had occurred up to the 19th inst. An official report in writing will be given in a few days by Dr. Stone.

The Cape Charles Quarantine Station on Fisherman's Island, Chesapeake Bay, was discontinued on the 15th inst. It is contemplated to erect permanent buildings on the island for quarantine purposes, if Congress decides to keep up a Government station at that point.

The cordon at Pensacola navy yard was ordered removed on the 25th inst., as there had been no new cases of yellow fever developed since the 7th inst., and the last case was convalescent on the 11th. The villages of Woster and Warrington have suffered severely from the scourge, and will be glad to have all restrictions removed.

Reports from Havana to include the 13th inst. show that there had been 19 deaths during the week. Surgeon Burgess states that he had inspected and fumigated twelve vessels bound to United States ports, among them the steamer British Empire from Vera Cruz bound to New York.

The disease is gradually disappearing from Vera Cruz, there having been only 11 deaths from yellow fever during the week ending October 4th. Surgeon Mamegra, sanitary inspector, has been ordered to return home at the close of the month: he reports no cases of yellow fever in the shipping for the past two months. The disease at Guaymas, Mexico, is pronounced to be yellow fever by experienced medical men, though it lacks some of the prominent symptoms of that disease, such as acid vomit, suppression of urine, etc. It is now on the decrease, only 7 deaths having occurred during the three days ending October 4th. In Hermosillo the cases have been more numerous but the deaths less frequent.

THE CHOLERA.—Consular reports from China indicate that cholera is gradually dying out, though sporadic cases still continue to occur. In August there were five deaths at Shanghai among foreigners, as against ten in July, while none are reported up to the 11th for September. Among the natives the mortality was in July 127, in August 120.

Quarantine restrictions have been modified at Malta so that vessels from quarantine ports are only detained sufficient time to cover ten or fifteen days from port of departure, the allowance for voyage being included. Twenty-two days are, however, required from Syrian ports, Barbary ports, Tunis, Turkish ports in the Levant, Austro-Hungarian ports, Algeria, and Cyprus.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, October 10, 1883.

GEORGE F. SHRADY, M.D., PRESIDENT, IN THE CHAIR.

CURIOUS LESION OF FEMUR—POSSIBLE SPINAL ARTHROPATHY WITH HEMATOMA.

DR. WACKERHAGEN presented a specimen with the following history: On September 17th he was called in consultation to see Captain W——, who was suffering from an affection of the left knee-joint. The patient, aged fifty-two years, was born in the State of New York. He was greatly prostrated, emaciated, and anæmic, with loss of appetite; temperature, $102\frac{1}{2}^{\circ}$ F.; pulse, 120 and feeble. The knee was flexed, the joint and surrounding tissues were greatly swollen, and appeared to be distended by some semifluid substance. He did not complain of severe pain unless pressure was made over the joint, or an attempt at motion was made, when his suffering was greatly increased. Upon paracentesis of the joint, only a small quantity of very dark-colored blood was discharged. The patient stated that he had always enjoyed good health until about three months prior to the operation, when he complained of pain at the knee-joint, and was treated for rheumatism. The pain was lancinating in character, and would occasionally disappear for a week at a time. A month later, he first noticed a slight swelling of the joint, which commenced to increase very rapidly three weeks before the operation. There was no family history of cancer or tuberculosis. The diagnosis was osteo sarcoma, and amputation advised.

The patient having consented to the operation, it was performed on September 19th, at the upper third of the thigh, under strict antiseptic precautions. Es-march's bandage was applied and very little blood was lost while ligating the vessels. Present—Drs. Gregory, Rockwell, Anderson, Hallock, and McCary.

The temperature fell after the operation to $100\frac{1}{2}^{\circ}$ F.; pulse, 100, and much improved in quality. The first dressings were not disturbed until the sixth day, when they were changed under the carbolyzed spray. Union by first intention, excepting a slight discharge of a brownish color through the inner drainage-tube, which gradually disappeared. Temperature continued to fall to normal, and did not at any time after the operation go above $99\frac{1}{2}^{\circ}$ F. The patient's appetite returned on the day following, and he is now in excellent health, and ready to return to his home in Ulster County.

The specimen included three inches of the upper end of the tibia and fibula, the lower half of the femur, the muscles and external integuments of the part.

Upon section, immediately after the operation, the muscles, particularly the adductors of the thigh, appeared glazed, flabby, and infiltrated with serum. They were abnormally dark in color, and lacked the characteristics of healthy muscular tissue.

Occupying the cavity left by the rarifying bone was a recent blood-clot, quite firm, of uniform color and consistency throughout; while the absence of pus or other inflammatory products was a marked feature.

The posterior surface of the patella was softened in the centre and eroded at its lower border. The articular surface was roughened and showed evidence of beginning changes.

The usual layer of compact tissue at the head of the tibia was wanting, and the cancellous structure, which was bright yellow from the large amount of infiltrated fat and the absence of the coloring matters of the blood, extended to the articular cartilage. The edges of the semilunar cartilage were ragged, and the articular cartilage covering the head of the tibia was perforated at one point and excavation beginning.

The medullary canal of the femur, from the point of the amputation downward, was enlarged, and toward the lower extremity cancellated tissue encroached upon the compact shaft until this was entirely replaced.

Then the cancellous bone itself disappeared, the space which had been occupied by the bone, except a part of the external condyle, being filled with the clot of blood referred to above.

A thin shell of articular cartilage remained at the seat of the inner condyle.

THE PRESIDENT regarded the case as remarkable and unique. He suggested spinal arthropathy as a possible explanation.

DR. BIRDSALL thought the period from the first development of symptoms was rather short for the joint changes accompanying locomotor ataxy. Again, the change in locomotor arthropathy manifests itself first in the articular cartilages and in the bone subsequently, whereas in Dr. Wackerhagen's specimen the articular cartilages were least affected.

THE PRESIDENT had recently seen two cases of spinal arthropathy in which the joints were in the condition described by Charcot, Buzzard, and others. The cartilages were eroded, the articular ends of the bones absorbed and expanded by pressure, the joint surfaces dry and crepitating, and the ligaments relaxed. In neither case was there pain on pressure, and the patients could walk reasonably well, allowing for the flail-like condition of the joints. In one case the patient was sent to the hospital for supposed tumor of the lower part of the thigh. In Dr. Wackerhagen's case it seemed that the hæmatoma was recent and accidental, and subsequent to the occurrence of the alteration in the osseous tissue.

DR. ELLIOTT asked if it might not be a case of purulent osteitis progressing rapidly.

THE PRESIDENT thought that if such were the condition considerable pus would have been found.

DR. GEORGE R. ELLIOTT presented specimens removed from the body of a man who had been operated upon for

CONGENITAL STRANGULATED HERNIA.

Wilson H——, eighteen years of age, United States, single, clerk by occupation, was admitted into the New York Hospital June 19, 1883, with the following history:

About 6 P.M. on the 17th inst. he began to have severe pain in the lower part of the abdomen, followed by nausea and infrequent vomiting. He was sailing in a yacht, and nothing was done for him till the next day at noon, when, after reaching land, an unsuccessful attempt at reduction of a tumor in the groin by taxis was made.

During the afternoon the vomiting became more frequent, and at night became stercoraceous in character. These symptoms persisted up to time of admission—12 M. of the 19th.

Examination revealed a tumor somewhat pear-shaped about the size of a hen's egg, occupying the right half of the scrotum, and extending to the external abdominal ring. The tumor was non-fluctuating, tender, and doughy to the touch, non-tympanitic on percussion, and there was no impulse on coughing.

Deep pressure over the abdomen gave rise to no pain, and there was no tympanites present. Vomiting was frequent and stercoraceous, the pulse could not be counted at the wrist, extremities were cold; in short, he was in a condition of partial collapse.

Operation was performed at 2.30 P.M. Upon opening the sac two drachms of dark fluid escaped. There was no marked odor present. The stricture was divided, and the contents of the sac, which were omental and intestinal, were not returned into the abdominal cavity, as they were thought to be gangrenous.

The patient did not rally after the operation, but remained unconscious, with a normal temperature, a very rapid and feeble pulse, and died at 2.30 P.M. the next day, forty-eight hours afterward.

At the autopsy, made eighteen hours after death, the lungs were found oedematous and congested.

The peritoneal cavity contained 50 c.c. of clear serum. The intestine in immediate proximity to the inguinal canal on the right side was slightly congested. There were no very marked signs of peritonitis present.

Four inches of the ileum, at a distance of eight inches from the caput coli, were found outside of the abdominal cavity, in immediate contact with the testicle. Omentum was also found in the sac beneath the coil of intestine, and at the point of constriction quite encircled the gut.

The loop of intestine which had been constricted was dark-colored in places, lustreless, coats thickened, and bound to the omentum beneath by recent adhesions. He did not consider the protruded gut gangrenous. The other organs were found normal.

The specimen was interesting, first with reference to the slight amount of peritonitis present. The only evidence of this was found in immediate proximity to the internal ring, where there was only a slight amount of congestion.

Another point of interest was the fact of a congenital inguinal hernia appearing at so late a date. It is not uncommon for a congenital inguinal hernia to become strangulated; but it is rather unusual for this form of hernia to appear for the first time as late as the eighteenth year of age.

An interesting question connected with the operation was, If the intestine was not gangrenous, and had been reduced completely, instead of being left in the sac, would it not have regained its normal condition more readily? The exact cause of death did not seem clear.

DR. W. M. CARPENTER referred to a case of strangulated hernia of the omentum, and a very small knuckle of intestine, in which he was called upon, many years ago, to operate on the fifth day after the strangulation occurred. When the omentum was exposed, it was found of a dark red color, but it was decided that it was admissible to reduce it completely. The general condition of the patient was bad; he did not rally from the influence of the ether and the operation, and died thirty-six hours afterward. At the autopsy there was no evidence of peritonitis, and the strangulated portion of the omentum and intestine had returned considerably toward the normal appearance, the restoration of the intestine being more marked than that of the omentum. He supposed at the time that the patient died of shock.

THE PRESIDENT thought it well, in case of doubt, to leave the contents in the sac rather than to return them to the abdominal cavity. If the constriction is divided completely, there is no special danger from the adoption of this plan, while there may be a great deal of danger from interfering with recent adhesions by attempting to reduce the contents entirely.

DR. J. C. PETERS, Chairman of the Committee, made a partial report on

EQUINE SCARLET FEVER.

It consisted chiefly of a communication from Dr. J. W. Stickler, one of the members of the committee (see p. 421). Dr. Peters referred to the historical fact that the first descriptions of scarlet fever and diphtheria were closely preceded by the occurrence of these diseases in horses.

DR. FERGUSON presented specimens, with the following history:

CARCINOMA OF THE STOMACH, LIVER, AND KIDNEYS,

occurring in a female, aged sixty, a native of Ireland, and single. Excepting rheumatism, from which she suffered thirty years ago, she has been well all her life. She had no family history bearing on her disease. There was no specific nor alcoholic history. She was received for treatment into the New York Hospital, on the 24th of July, 1883. For one year previous to her admission she had been losing flesh and strength, and during the

last six months of that time she suffered from nausea and vomiting after taking food. She complained of pain, not constant, but present the greater part of the time in the region of the stomach. A tumor could be felt in the epigastrium.

On examination, area of liver dulness was extended, and there was an area of dulness in the epigastric region over the tumor above alluded to, and continuous with the dulness over the liver area.

She did not improve on appropriate diet and medication, and after three weeks' stay in the hospital she began to vomit blood (which did not characterize her first vomiting) in large amounts; she also passed blood from her bowels. This was followed by collapse, and she died within twenty-four hours of the first appearance of hemorrhage.

Her temperature, which had been elevated— 100° to 101° —previous to her hemorrhage, became subnormal after it— 97° to 98° .

Her pulse and respiration became accelerated, the former varying from 100 to 120, and the latter superficial and from 30 to 40 per minute.

The cancerous masses in the organs involved are spheroidal in shape, varying in size from a pin-head to a pullet egg. Microscopically they are characterized by an abundance of small cuboidal cells, closely packed together and supported by a small amount of stroma, arranged into alveoli of very variable shape and size.

The Society then went into executive session.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Annual Meeting, October 22, 1883.

DAVID WEBSTER, M.D., PRESIDENT, IN THE CHAIR.

AFTER the reading of the minutes of the last stated meeting,

THE REPORT OF THE COMITIA MINORA

for the year was read, including the recommendation of eighty-one candidates for election to membership.

DR. AUSTIN FLINT, JR., moved to lay the report upon the table until after the election of officers.

THE PRESIDENT decided that the motion was out of order.

The recommendation of the Comitia was adopted.

THE EXPULSION OF DR. H. H. KANE.

The Comitia further reported recommending that H. H. Kane be expelled. The recommendation was unanimously adopted.

The Treasurer, DR. O. B. DOUGLAS read his report, which, together with the report of the Auditing Committee, were accepted and ordered entered upon the minutes.

HONORARY MEMBERSHIP.

On motion, DR. J. P. MILHAU was instructed to cast an affirmative ballot for Brevet-Lieutenant-Colonel Bennett A. Clements, Surgeon U.S.A., for honorary member.

ELECTION OF OFFICERS.

THE PRESIDENT appointed as Tellers, Drs. H. G. Piffard, W. T. White, E. F. Ward, W. T. Alexander, and Geo. F. Carey, who subsequently reported that 599 ballots had been cast, and that of these—

Dr. S. Oakley Van der Poel had received 375 for President; Dr. Andrew H. Smith, 380 for Vice-President; Dr. Wesley M. Carpenter, 385 for Secretary; Dr. Charles H. Avery, 380 for Assistant Secretary; Dr. Orlando B. Douglas, 384 for Treasurer; and Dr. F. R. Sturgis, 385; Dr. David Webster, 383; Dr. Daniel Lewis, 377; Dr. F. R. S. Drake, 373; and Dr. Joseph W. Howe, 378 for Censors.

Dr. T. Gaillard Thomas had received 220 for President; Dr. Charles A. Leale, 215 for Vice-President;

Dr. E. A. Judson, 210 for Secretary; Dr. P. Brynberg Porter, 215 for Assistant Secretary; Dr. H. D. Nicoll, 208 for Treasurer; and Dr. Charles McBurney, 224; Dr. Richard H. Derby, 208; Dr. Charles S. Wood, 210; Dr. Charles Hitchcock, 213; and Dr. Thomas H. Burchard, 215 for Censors.

The President declared that those members who had received the majority of all the ballots cast had been elected to the offices for which they had respectively been nominated.

DR. CHARLES S. WARD, Chairman, submitted the

REPORT OF THE COMMITTEE ON ETHICS,

in which it was stated that only three cases had been brought before the Committee during the year, that one had been settled by arbitration, and the other two had been reported to the Comitia Minora.

REPORT OF THE BOARD OF CENSORS.

DR. H. B. CONRAD, Secretary, read the report in which it appeared that the work of causing compliance with the medical act of 1880, and of punishing offenders against that law, had been successfully continued.

It also appeared that a suit had been successfully carried on against the United States Medical College, which had no legal right to confer the degree of Doctor of Medicine.

Special reference was made to the importance of having some common standard of qualifications, which shall govern the admission of candidates for the privileges of the practice of medicine and of the appointment of some proper board which shall pass upon the fitness of the future practitioners of the State of New York.

The Board, adopting the recommendation of the Counsel, E. C. Ripley, Esq., earnestly recommended that the faculties of the various schools endorse no diplomas in which there is the slightest ground for doubt; that it would be better if all candidates for the practice of medicine holding diplomas requiring endorsement should be compelled to pass an examination before being allowed to register.

The other members of the Board were Dr. Daniel Lewis, Chairman, Drs. J. D. Bryant, F. R. Sturgis, and Walter R. Gillette.

The report was accompanied by a report from the Counsel, giving a detailed account of the legal work which had been done by the society.

DR. A. E. M. PURDY, Chairman, read the

REPORT OF THE COMMITTEE ON PRIZE ESSAYS,

in which it appeared that only one essay had been submitted, and the committee deemed it unworthy of a prize.

THE SECRETARY read the following resolutions received from the Medical Society of the County of Westchester:

Resolved, That the representatives of this County in the State Legislature be requested to urge the passage of an

ACT TO PROHIBIT ALL MEDICAL COLLEGES FROM GRANTING DIPLOMAS,

and requesting all candidates for the degree of Doctor in Medicine to appear before a State Board of Medical Examiners, who shall recommend successful candidates to the Regents of the State University for a diploma.

Resolved, That the Secretary send a copy of this resolution to the members of the Legislature from this County, and to every County Medical Society in the State, and urge them to take the same action.

The communication was referred to the Comitia Minora.

DR. J. C. PETERS made a verbal report on

EQUINE SCARLET FEVER,

and referred especially to communications on that subject already published in THE MEDICAL RECORD by Dr.

Stickler. The Committee was continued, increased to five, with power to fill vacancies, and accept resignations subject to the will of the Society.

On motion, the Treasurer, Dr. O. B. Douglas, 123 East Thirty-sixth Street, was instructed to send by mail a volume of the "Transactions of the State Medical Society for 1883" to any member who requested the same, not to exceed one hundred and twenty volumes, for *one dollar* per volume.

The Society adjourned to meet at the College of Physicians and Surgeons, on November 26th, at 8 P.M.

Correspondence.

RANDOM NOTES AND OBSERVATIONS OF A TRIP THROUGH THE GREAT NORTHWEST.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR: It is but two decades that the settlers in Minnesota have held undisputed possession of its soil. The horrors of the great Sioux massacre, which occurred in 1862, are still fresh in the memories of many men. In view of these facts, the rapid growth and development of the former "land of the Dakotahs," and more especially of its twin cities, St. Paul and Minneapolis, must strike us as truly phenomenal. Exactly why these neighboring towns are still called twins it would be difficult to determine, however, for the only Siamese bond that at present links them is the reciprocal spirit of eager rivalry, watchful jealousy, and utmost contempt. Still, it seems quite possible that the very ardor of mutual antipathy has been instrumental in raising both cities far above the level of other towns in the State. So that here again the life of two cities illustrates an old experience, that intense competition may prove an unmixed blessing to both competitors. The universal activity and restless enterprise of these pioneer cities is but faintly reflected in their professional life, in so far, at least, as this relates to medicine.

The stream of practice flows along rather slowly and quite smoothly. But it is the slowness of equanimity, and not of sickly, exhausted lethargy. Of course there are occasional homœopathic and other irregular eddies. But these are utterly impotent to disturb the main current. Such distressing whirlpools and rapids as we Eastern code-contentionists wilfully and wickedly create, are nowhere to be found. Indeed the Western medico generally does not, apparently, envy us the open display of bitter feud and strife within the ranks of a profession that can ill afford to merit public scorn and ridicule.

Our Western *confrère* has perhaps heard of the code. In rare instances he has even "read it some." That is the old one. But he does not hanker after it. Nevertheless, he tries to live the life of a gentleman. He feels satisfied that he can do this through the prompting power of his own impulses; hence he cares very little for the old code, and just about as much for the new one. He upholds regularity, especially in the matter of sending bills. Yet he rarely hesitates to meet his homœopathic brother—openly, as they do most things out there in that benighted West, not on the sly, as they do some things down here. The result is a happy one. Almost universally, in the far West, there exists a feeling of harmony within the profession that sounds to Gotham ears like the strains of sweet music long forgotten, though dearly loved. The evident moral of the matter is this: let the western doctor come East to learn the refinements of differential diagnosis; but by all means let us go West to be taught the refinement of undifferentiated fellowship. Evolution is doubtless a great science, but we have not yet reached that point of mutability which will allow a man born without the instincts of a gentleman, to become metamorphosed into one through the potent agency of a code. And the gentleman-born carries within his breast

a better, brighter, nobler code than human pen or printer's ink can ever devise.

There is no dearth of doctors in St. Paul and Minneapolis; still the profession is not overcrowded, and there is room for good physicians. As for the two years' product of our vast grinding mills, that species of dazzling ignorance would find transplantation to Minnesota soil unprofitable, if not ruinous. It could never take root there and bring forth choice blossoms of bungling stupidity, gross carelessness, and reckless behavior generally.

Some of the Westerners are so pachycephalic and vulgar that they fail utterly to appreciate such dainty delicacies. And what they do not appreciate they sometimes shoot. At least so the writer was credibly informed, although he never saw it done.

Dr. C. H. Boardman, of St. Paul, the medical director of the Northern Pacific Railroad, kindly gave your correspondent a few points about the practice of medicine in that city and Minneapolis. It would appear that the largest incomes, in both towns, are derived by homœopaths. And in neither does it exceed \$15,000. The established physician in good standing earns on an average between four and six thousand dollars. The usual office fee is one dollar, and a visit to the house of the patient two. Consultations pay five dollars. Confinements from ten to twenty-five. There are no dispensaries to lure the willing patients from the office of the doctor. A majority of the people habitually pay their bills. The inevitable blackleg and deadhead is represented by an insignificant minority. The personal relations between the representatives of the two schools are quite good. Quarrels but rarely occur. Consultations between them are infrequent, but entail no far-reaching consequences, and rarely engender even temporary partisan dissensions.

Pure science naturally has few votaries there; but the average practitioner is a busy, intelligent man, fertile in resource, quick to imitate what is new, and eager to advance his art with himself. It should be understood, however, that art precedes self, in this statement, solely by courtesy. But it may be comforting to our Western brethren to be assured that such precedence is not utterly unknown, even in the enlightened East.

As regards lady practitioners, they appear to be fairly successful, and while they can hardly claim to excel the average male physician, they are justly entitled to all the credit that belongs to holding one's own, even when handicapped by natural and artificial disadvantages. The specialties are at present but little developed, although oculists and aurists are beginning to crop up rather numerously.

Dr. Ames, the Mayor of Minneapolis, assured the writer that the professional duties and responsibilities of a large office practice were quite compatible with the faithful and energetic management of municipal affairs. In an eastern city of over one hundred thousand inhabitants a physician elected to the mayoralty would have to give up that office, or his office practice would give up him. They appear to govern less West than East, although they may seem to require more government.

Your correspondent has purposely dwelt at some length on the local aspect of medicine in St. Paul and Minneapolis, for what was said concerning these cities applies to a great extent to all the larger towns of the region visited. As regards the smaller places, a young physician locating there would have to take his chances. If fortunate, the settlement may quickly prosper, and he would then be assured of a rather handsome competence. On the other hand, it might remain stationary, or even retrogress. In that case, unless he could afford to begin anew elsewhere, his life would remain one of toil, anxiety, and hardship, unilluminated by any legitimate hope of future prosperity. There is a great deal of quiet heroism and touching pathos about the weary struggle for existence of many a medical man in the little border-towns of advancing civilization. Life there is a rugged

reality, very apt to quickly dissipate illusions, and, alas, too often to inflict, through shattered hopes and dire disappointments, a wound that rankles but can never heal. Many a promising career has there been wrecked through insufficient equipment, a mistaken sense of power of sustained energy, or a yielding to temptation in the shape of gambling and other vices. Yet the man of conscious strength and integrity may easily walk unscathed through the alluring valley of sin, and avoiding its numerous pitfalls, safely climb the hill of success and eminence.

This little wayside sermon is preached for the benefit of the young eastern graduate, who is uncertain where to settle. Let him not blindly believe that in the New Northwest fame and money will be poured into his lap undeservedly, or with but slight exertion. Let him rather take to heart the words of Dante, and—

"Think not that under the shade of
Canopy reposing, fair fame is won,
Without which, whoso'er consumes his days,
Leaveth no vestige of himself on earth."

The gospel of overwork has latterly been preached into quite a fashion, and with some amount of justice, one may readily concede. But work should not be confounded with overwork. It may often, in individual cases, be difficult to draw the line between the two. Yet, surely, where the general welfare of a village, a town, or any large community is concerned, it is safer to err on the side of overwork than on that of idleness. America owes its proud greatness to American work, call it overwork if you will, but not to transatlantic habits of underwork, or indolence.

A prominent German guest of Mr. Villard on this excursion, a quick observer and close student of the life of various nations, said that if the Teuton laborer and farmer could but be taught to work as the American does, he could make as much of a proverbially poor country as we are making of a proverbially rich one. In a concluding letter the writer hopes to bring to a close these random observations of a trip that, to him at least, was highly entertaining and instructive.

Very truly yours,

EDMUND C. WENDT.

136 WEST THIRTY-FOURTH STREET,
New York, October 18, 1883.

New Instruments.

THE ELECTRO-OSTEOTOME.

A NEW INSTRUMENT FOR THE PERFORMANCE OF THE OPERATION OF OSTEOTOMY.

By MILTON JOSIAH ROBERTS, M.D.,

NEW YORK,

PROFESSOR OF ORTHOPEDIC SURGERY AND MECHANICAL THERAPEUTICS IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL; VISITING ORTHOPEDIC SURGEON TO THE CITY HOSPITALS ON RANDALL'S ISLAND, ETC.

GRANTING that surgeons, especially of late, have too frequently resorted to operative procedure for the relief of bony deformities; that they have shown a disinclination to adopt the more judicious, safe, and rational treatment by means of suitably constructed orthopedic apparatus, there is nevertheless a large and diversified class of cases which can only be successfully dealt with by operative interference. Many patients suffering from bony deformities that would have been amenable to mechanical treatment in their early stages come under the observations of the surgeon too late in life to avoid an operation. Again, in general hospitals and amputatory clinics, where we have to do even with young subjects, the expense of orthopedic apparatus and the necessarily long continuance of mechanical treatment to effect a cure, may deprive the patient of therapeutic measures which would be adopted in private practice, thereby relegating his destinies to the domain of osteotomies.

It therefore becomes the subject of legitimate inquiry as to the best means of performing these operations.

It is not the purpose of this communication, however, to review the various operations of Mayer, Annandale, Barton, Adams, Ogston, Boswell, Reeves, Macewen, and other surgeons; nor to discuss in detail the merits and demerits of the tools which have been used by operators other than myself. I wish simply to call attention to an instrument which, in my opinion, in a large range of cases possesses important advantages over any that have hitherto been employed. This conclusion has been reached after a sufficiently extended and varied personal experience from which to make deductions.

The instruments used by the surgeon in the operation of osteotomy¹ may all be classified under the following heads: 1, chisels; 2, cutting forceps or nippers; 3, shears; 4, gimlets; 5, drills; 6, saws.

Of these instruments the saw possesses the superior qualities of rapidity, certainty, and evenness of cut. Furthermore, by its use the concussion and shock incident to the employment of the chisel and mallet, are entirely avoided. Why then do surgeons ever resort to the use of chisels, drills, etc.? The reasons are as follows:

First, as to the use of the long or straight saw. Though admirably adapted to the direct application of hand-power, its to-and-fro movements render it hazardous to the soft parts under many circumstances. This objection, however, has been very successfully overcome in that form of the instrument devised by Dr. George F. Shady, in which the blade is operated through a protecting metallic sheath. His saw is very narrow, and was especially designed for simple subcutaneous transverse section of bone. Another objection to the straight saw is the impossibility of executing the to-and-fro movements in certain situations. Moreover, it is not well adapted to the removal of conical segments from bone deeply embedded in the soft parts. And, finally, it is, for the most part, impracticable to use it in making longitudinal cuts.

I pass in review the objections to the use of the hollow (trephine) and chain saws, which must be patent to all.

The circular saw, though equally well suited in form to the removal of transverse wedges of bone and the making of longitudinal cuts, and not open to the objection of to-and-fro movements, has never been extensively employed by surgeons. The reasons for its disuse lie, then, not in its form, nor in its rotary movement. Carrying our inquiry a little further, however, they become evident. Paramount among these is the impossibility of a direct application of hand-power to the evolution of the rotary motion of the circular saw. If manual power be used at all, some mechanism is necessary in order to develop rotation of the blade.

Two difficulties present themselves in the adaptation of hand-power to driving the circular saw. One of these is the disadvantage with which force is applied at the axis of motion to overcome resistance at the peripheral margin. The other is the rapidity of rotation necessary to effective work. If the problem were the construction of a hand machine to rotate a circular blade meeting with no resistance at its periphery, nothing would be more simple. Or, if power could be applied at the margin of the blade to overcome resistance at the axis of motion, the device of such a machine would still be a very simple mechanical problem. It is, then, the great resistance which the serrated edge meets when in contact with bone, and the necessity of overcoming this by power applied to the arbor of the blade that make the task of construction and propulsion so difficult.

A number of ingenious inventions have been offered, but when put to the test of sawing bone on the living subject have not answered in practice what they promised in speculation. As a rule their blades have been placed at a right angle with the main shaft, and, on this

account, have been difficult to hold in position. They have, without exception, been deficient in power, or speed, or both. Of the hand or foot-motors which have been devised for driving circular saws, that which is ordinarily used for dental purposes is the most complete in its workmanship and satisfactory in its execution. But the blades of these saws are of too small diameter to frequently be of service to the surgeon, and the engines and gearing which drive them are not built of sufficient strength to admit of the employment of larger saws. In concluding the adduction of objections to the circular saw it is necessary to state that surgeons have always experienced great difficulty in protecting the soft parts while using it.

From what has been said it will be seen that in order to produce an osteotome of superior excellence to any we now have, it must be capable of dividing any bone in the human body, from the smallest to the largest, such division to be rapid, smooth, and certain, even though it be of the hardest bone; the blade of the instrument should readily follow the direction given it by the surgeon; it should be adapted to simple, coniform, and longitudinal osteotomies in any situation, of easy manipulation and imparting to the hand of the surgeon all the sensations that could be appreciated with a probe; possessing strength and portability, and not likely to get out of order; and, finally, capable of being used without danger to the soft parts.

Such an instrument is illustrated in Fig. 1, from a photograph. It is here represented as it appears when

Fig. 1.

suspended and grasped by the hand of the surgeon ready for action. It consists of a small electro-motor actuated, through insulated wires, by a powerful battery and carrying a circular saw that revolves in a plane parallel with that of the central shaft. A hollow cylinder with a collar-like base is firmly screwed to the end plate of the motor and forms the handle of the instrument. Upon this a soft-rubber hand-piece, fashioned like that of a carpenter's chisel, is slipped and fastened in position; an arrangement which adds security to the surgeon's grip when operating. The central shaft of the motor is continuous through the hollow hand-piece. At its distal end, a right-angle mitre-gearing connects it with the saw-bearing pivot. A metallic shield guards the proximal aspect of the serrated blade. Shields are provided for each size

¹ The word is here used in its broadest signification.

of saw. The depth of cut which it is possible to make with a given saw of course depends upon the diameter of the blade, being a trifle less than the distance from the centre to the periphery. The direction of the kerf, however, can be so modified as to enable the operator to easily divide a bone having a greater diameter than half that of the saw he is using.

The saws which I now use have been constructed with great care in accordance with my directions. Prior to their adoption I made extended experiments with many forms and sizes of teeth and thicknesses of blade. In order to adapt the saw to the requirements of individual cases, I have thus far found it desirable to have four sizes, viz.: 32 ($1\frac{1}{4}$ inch), 41 ($1\frac{5}{8}$ inch), 51 (2 inches), and 63 ($2\frac{1}{2}$ inches) millimetres in diameter. The teeth are coarse in proportion to the size of the saw, and number 18, 16, 14, and 12, respectively, per linear inch (25 mm.). These saws are so ground as to gradually diminish in thickness from the periphery to the centre. Binding in the kerf, when making deep cuts, is thus prevented. If the blade be made of the same thickness throughout, the side friction will be so great that the motor will be unable to drive the saw with adequate force and speed after it has fairly entered the bone. Provision is still further made for increasing the width of the kerf over that of the saw by giving to the teeth a little "set." This latter procedure is a very delicate operation and requires considerable mechanical skill to do it properly. It is important that the alternate lateral inclination of the teeth should be perfectly regular throughout; otherwise, the smooth and easy cutting of the saw will be interfered with. In form, the serrations are slightly *raked* instead of *hooked*. They are so filed that their cutting edge is at a right angle with the blade, instead of being at an oblique angle, as in most circular saws. The blades are made of the best steel and have a special spring temper. They are not so hard as those used in cutting iron or brass, nor are they so soft as those used in cutting wood. Saws tempered for metal work, are too brittle for sawing bone; they would be apt to snap in the kerf, should the operator permit any lateral deviation of the blade. Tempered for sawing timber, the teeth would soon become dull by contact with hard bone. Lastly, great pains is taken to have the blades of the saws absolutely free from "buckle" or twist. This is necessary in order that they shall run perfectly true and not bind in the kerf.

Upon the plate at the opposite end of the motor from that to which the hand-piece is attached are two binding-posts, which receive the ends of the electrodes connecting the instrument with the battery. Considerable experimenting was necessary in order to determine upon a form of battery having sufficient duration and power without unnecessary bulk. A general idea of the battery which I use can be gained from Fig. 2. It is a *zinc carbon* battery. The cells are of glass and ten in number. Their dimensions are 2 x 7 x 8 inches. Each cell contains one zinc plate 6 x 8 inches, placed between two carbon plates of equal size. The fluid used is a solution of bichromate of potassium, known as red acid, somewhat stronger than that used in the ordinary faradic batteries. The duration of maximum power furnished by this battery is from twenty to twenty-five minutes, sufficient time for the performance of any number of osteotomies which the surgeon will ever be called upon to do at one sitting. The battery is only permitted to be in action during the brief periods required for making sections of bone. The zinc and carbon plates are firmly fastened to a board which is suspended above the glass cells by means of coiled springs, as shown in the cut. A lever at the side of the battery-box furnishes the means of submerging the plates in the fluid at pleasure, by simply depressing it. Upon releasing the lever, the plates are automatically drawn out of the fluid by the action of the springs. Conservation of battery-power is thus made perfectly feasible, for as soon as the surgeon has made a simple or cuneiform section of bone, the lever

can be released and the further working of the battery prevented until he is again ready for action. In transportation the fluid is emptied from the cells. The framework which serves for the suspension of the plates is so constructed that it can be quickly taken apart and laid in the battery-box on top of the board to which the plates are fastened. This arrangement makes the battery very compact and readily transportable.

FIG. 2.

"When using the electro-osteotome, it is suspended by a solid rubber cord, six or seven millimeters in diameter, from the cross-bar of an adjustable crane screwed to the edge of the operating-table. In this way all weight is removed from the hand of the surgeon, and leaves the instrument as thoroughly at his command as would be the most delicate probe.

The high rate of speed (about six thousand revolutions per minute) and the great force with which the saw is driven, necessitates skilful manipulations and great vigilance on the part of the operator in using the osteotome. The limb of the patient should be firmly held by an assistant, and the precise direction and extent of the cut determined upon before permitting the first impact of the blade against the bone. The keen eye and sense of touch of a skilful surgeon will readily appreciate whether there is any departure from the predetermined line of incision, or binding of the blade in the kerf.

And now as to the means of protecting the soft parts. Fig. 3 represents one form of protecting retractor, which I use in osteotomy operations. It was made for me by Messrs. Stohlmann, Pfarre & Co., and its form is specially adapted to the supracondyloid operation for genu-

FIG. 3.

valgum. Two such instruments as is here represented form a pair. They are introduced one at a time through the linear incision in the soft parts, carried down to the bone and passed around it, much after the fashion of applying obstetric forceps. When in position they are pressed apart so as to make room for the blade of the osteotome. By their use there is no possibility of injuring any of the soft tissues while operating. The retractors are provided with a double curve at each end, one large, the other small, so as to adapt them to large and small bones.

In conclusion, I may say, in illustration of the labor and time-saving qualities of the electro-osteotome, that in operating for double knock-knee and bow-legs, I have

removed wedges of bone in from thirty seconds to one minute that would require from fifteen to thirty minutes to chisel out. The incision made with the saw is clean, the severed ends of the bone are not comminuted, and the two cut surfaces can be readily and perfectly coaptated.

The mechanical details connected with the perfection of the instruments and battery above described have been very numerous, vexatious, and at times discouraging. In prosecuting this work I have been the recipient of many courtesies at the hands of Mr. Edward P. Suter, of the Electro-Dynamic Co., Messrs. Wait & Bartlet, and the Western Electric Co., all of this city.

Army and Navy News.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from October 13 to October 20, 1883.

BACHE, DALLAS, Major and Surgeon. Assigned to duty at Willett's Point, New York. S. O. 238, par. 1, A. G. O., October 18, 1883.

HUNTINGTON, DAVID L., Major and Surgeon, by direction of the President, will, until further orders, take charge of the office of the Surgeon-General of the Army and perform the duties pertaining thereto. S. O. 234, par. 3, A. G. O., October 11, 1883.

STERNBERG, GEORGE M., Major and Surgeon. Granted leave of absence for one month, to date from October 6, 1883, with permission to go beyond the limits of the Department, and to apply for extension of one month. S. O. 134, par. 3, Department of California, October 4, 1883.

TAYLOR, MORSE K., Major and Surgeon. Assigned to duty at Fort Sill, I. T. S. O. 210, par. 4, Department of the Missouri, October 13, 1883.

HEIZMANN, CHARLES L., Captain and Assistant Surgeon. Granted leave of absence for six months, with permission to go beyond sea. S. O. 235, par. 3, A. G. O., October 15, 1883.

Official List of Changes in the Medical Corps of the Navy, for the week ending October 20, 1883.

BROWNE, J. M., Medical Director, ordered as member of the National Board of Health.

CLEBORNE, C. J., Medical Inspector, ordered to the U.S.S. Hartford at Panama, on duty connected with a court martial.

GORGAS, A. C., Medical Inspector, detached from Naval Hospital, Chelsea, Mass., November 10th, and ordered to the Naval Hospital, Mare Island, Cal.

HEFFINGER, A. C., Passed Assistant Surgeon, ordered to temporary duty at Navy Yard, Portsmouth, N. H.

HORD, W. T., Medical Director, ordered to the U.S.S. Hartford at Panama, on duty connected with a court martial.

WHITING, ROBERT, Passed Assistant Surgeon, granted leave of absence for three months.

The orders of W. J. Simon, Surgeon, and M. H. Crawford, Passed Assistant Surgeon, in last week's report, should read U.S.S. Shenandoah, instead of U.S.S. Trenton.

FELICITY AS AN OBJECT OF SANITARY RESEARCH is the novel title of an address delivered recently by Dr. B. W. Richardson before the Sanitary Association of Great Britain. That one should not only have a healthy life and a long life, but a happy one, was the burden of the oration. Felicity based on good plumbing, tight cellars, no cesspools, running water, perfect ventilation, no stimulants, no narcotics, no pastry, no bacteria—this is to be the object of the future rational man's endeavor.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending October 23, 1883:

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
<i>Cases.</i>								
October 16, 1883.....	0	59	40	4	17	37	0	0
October 23, 1883.....	0	59	45	1	13	38	0	0
<i>Deaths.</i>								
October 16, 1883.....	0	19	5	3	4	13	0	0
October 23, 1883.....	0	20	12	1	2	20	0	0

THE USES OF HYDROBROMIC ACID.—Dr. Joseph Parrish, of Burlington, N. J., writes, referring to an article by Dr. C. L. Dana (*Journal of Nervous and Mental Diseases*) on hydrobromic acid, that he has recently used it in two cases: "In one, it relieves the insomnia in f3j. doses, taken P.M., say three doses a few hours before retiring. The other is a neurasthenic case, in which there is enlargement and hardening of sciatic nerve and general neuralgia. In this case I have given the bromides in several forms with but little impression, except bromism. Hoping to avoid the bromism, I resorted to 10 per cent. acid, with the effect of bringing out the bromism as distinctly as when she took either of the salts. In direct opposition to this case I have a lady of forty, an epileptic, who has taken bromid. potassium, in doses of from half a drachm to a drachm and a half, three times daily for the last fourteen years without the slightest sign of bromidism."

Dr. Squibb writes of hydrobromic acid in *Ephemeris*: "Its most common and probably most effective use, is as an addition, either constantly or intermittently, to solutions of the bromides when these have to be taken for a long time and in full doses. In this way full bromine doses may be easily maintained, while the effect of the bases is diminished. Full doses of the acid are difficult to administer on account of its intense acidity. It is best given with sugar, or with syrup, or with syrup of acacia, and with lemon syrup it is somewhat like lemonade. Large dilution is always advisable. The dose of the officinal acid is 2 to 4 fluidrachms, which is equal in bromine to 17 to 34 grains of the potassium salt. An equivalent dose of the 34 per cent. acid is about 27 to 54 minims. This acid is very useful in making extemporaneous solutions of many bromides. For example, the very effective bromide of lithium may be very easily made extemporaneously by prescription, by simply saturating, or nearly saturating, the acid with lithium carbonate."

MAD WITNESSES.—The United States Supreme Court has recently decided: "A lunatic or person affected with insanity is admissible as a witness if he has sufficient understanding to apprehend the obligation of an oath, and to be capable of giving a correct account of the matters which he has seen or heard with reference to the questions at issue; and whether he has that understanding is a question to be determined by the court upon examination of the party himself, and any competent witnesses who can speak to the nature and extent of his insanity."

THE DISEASE OF THE LATE COMTE DE CHAMBORD.—A recent issue of the *Gazette de Médecine et de Chirurgie* contains a long report upon the malady of the late Comte de Chambord, from the pen of Dr. Vulpian, the

physician so much favored by the deceased prince. Dr. Vulpian gives a detailed account of the post-mortem examination, and makes afterward an important admission. He says: "There can be no doubt that a diagnostic error was committed during the lifetime of the deceased, since we have not found the cancer we expected to meet in the epigastric region. In fine, the malady of the Comte de Chambord has been characterized, from an anatomical point of view, by ulcerations of the mucous membrane of the stomach, and especially of the mucous membrane of the gullet, and, from a clinical point of view, by a collection of symptoms that rendered at least probable the existence of a cancer in the stomach. This is an extremely rare, and, I think, a very interesting fact, for which reason I have published an account of it."

ITALIAN DOCTORS PUZZLED.—For some time past the medical faculty in Italy have been sorely puzzled by a strange disease of a contagious nature, which, although in its clinical features is somewhat like yellow fever, differs in some essential points from that and all other known diseases. The first appearance of the strange malady took place at Torre Annunziata, in June last. Early in that month a man attacked by fever, accompanied by a grave form of jaundice, died. During the interval since then fifteen other cases, followed by death, have occurred, exclusive of those last reported. In all the first symptoms were those of jaundice, followed by high fever, extreme prostration, and stupor. No case was accompanied by vomiting. Professors Semmola and Petronio were unable, in the post-mortem examinations they made, to recognize the pathological signs of any known clinical deaths or the characteristics of yellow fever. They found, however, enlargement with ulceration of the spleen, great fluidity of blood, and other indications of contagion, and describe the malady as a serious form of jaundice caused by infection, and belonging to the infectious typhoid-jaundice group of diseases.

BILLROTH'S LINIMENT AGAINST LUPUS.—

R. Potas. sod. 5. grammes.
Iodin. metallic. 0.10
Glycerin. pur. 50.

M. Apply with cloths to the affected region. Internally, give cod liver oil and depuratives.

A NOVEL METHOD OF BLEEDING.—The *British Medical Journal* of September 15th notes the relief of a case of cerebral congestion through blood-letting by means of a novel device. The patient, a fat, plethoric lady, fifty years of age, came under the charge of Charles Coppinger, F.R.C.S.I., and at the time of the surgeon's visit was in a condition of stupor, out of which she could be roused with some effort, but only to relapse into sleep again. Her breathing was heavy, and she presented all the symptoms characteristic of an overloaded vascular system. The indications for treatment were plain, and leeches not being obtainable, depletion by means of venesection was proposed. The friends of the patient, who were ladies, gave their consent, but were horrified at the suggestion of so barbarous a proceeding, and Mr. Coppinger, anxious to spare them the sight of blood, then and there conceived the idea of substituting the aspirator for the lancet. The patient, who had not long before been treated for hemicrania by hypodermic injections of morphia, was roused up and told that the needle was about to be "inserted into the skin of her neck, to which she at once consented." The needle of the aspirator was then passed into the external jugular vein, which was much distended, and four ounces of blood were withdrawn without difficulty. The result of this trial being satisfactory, the surgeon repeated the operation in the course of a half-hour, abstracting six ounces more of blood. The patient was speedily relieved of her alarming symptoms, and neither she nor her attendants suspected that she had been bled, until the procedure was subsequently explained to them.

A PROMISING SPECIALTY.—The *Canada Medical and Surgical Journal* places the proportion of people in the United States who have corns at one to five, and then asks: "If it costs \$1.30 to effect a cure in each case, what would be the cost of placing every person on a sound footing?" The answer is not difficult, says the *Detroit Medical Age*: 5:50,000,000 :: 1:10,000,000 × 1.30 = \$13,000,000. Here is manifestly a rich field for cultivation. Of all the specialties that of chiropody is, we believe, the least crowded. In our city of 140,000 we have but one, and, as far as we are able to ascertain, a similar distressing dearth is prevalent throughout this country.

SENSATION AND CONSCIOUSNESS NOT SIMULTANEOUS.

—In the *Comptes Rendus*, M. Beaunis has given an account of his interesting investigations to determine the time between the instant of excitation of a sense and the instant at which the person indicates by a signal that he has become conscious of the sensation. In the matter of smell, for instance, he gives a table of the numbers obtained with ten substances, these ranging from thirty-seven hundredths of a second for ammonia and forty-six for acetic acid, to sixty-three for mint, and sixty-seven for carbolic acid; in the case of musk, M. Beaunis was unable, notwithstanding repeated attempts, to fix precisely the moment of the smell sensation. The numbers obtained are said to show that the reaction time for smell is longer than that for touch, sight, and hearing.

THE DRY OR MOIST TREATMENT OF CHRONIC PURULENT INFLAMMATION OF THE MIDDLE EAR.—Dr. L. S. Oppenheimer discusses the relative value of the dry and moist treatment of middle-ear inflammation, and advocates the former (*Louisville Medical News*). His method is as follows: The ear is first thoroughly cleansed by means of a syringe and warm water; it is then carefully dried and the powder insufflated, or applied on a piece of cotton through the speculum, the cotton being allowed to remain for twenty-four hours. The cotton absorbs the fluids and prevents them from again irritating the external ear. The powder may be insufflated through a goose-quill, care being taken to apply it to all parts of the cavity. The above is repeated daily for a few days, then on alternate days, then once a week for a week or two. The syringe is not required after the first two or three days. The agents which I employ in nearly all cases are iodoform and salicylic acid, the latter being applied daily whenever granulations exist; a few days after iodoform is substituted. It is of importance that absorbent cotton be inserted after each application, and removed the following day. It is also a good practice to use the Politzer air-bag once or twice a week during the treatment, as it helps to dislodge inspissated pus, tenacious mucus, etc. In brief, then, thorough cleansing before each application, insufflation of dry powders, and keeping the parts as dry as possible between the periods of treatment, will, I think, cure nearly if not quite all of these cases in a much shorter time than any other kind of treatment.

THE CONTAGIOUSNESS OF ECZEMA.—A correspondent of the *Boston Medical and Surgical Journal* describes the following case, asking if it was a coincidence. To us it appears more likely to be mistaken diagnosis: A., aged nineteen years, while living in New York, was attacked with acute general eczema. He returned to Boston, and slept a few nights with his brother W., and afterward with another brother, N. In about ten days W. and N. were both seized with this affection, and within a fortnight W.'s lady love also broke out with it. They were all healthy people, and had never before had any skin disease. Only two of the four were surrounded by the same hygienic conditions. Did one catch the disease from the other, or was it a coincidence? Duhring says: "Eczema is not contagious. It cannot be acquired from being in contact with or from handling the patient; nor can it be taken from the discharge."

GUNSHOT WOUNDS.

A LECTURE DELIVERED AT BELLEVUE HOSPITAL MEDICAL COLLEGE, OCTOBER 24, 1883.

By SIR WILLIAM MAC CORMAC,

SURGEON TO ST. THOMAS' HOSPITAL, LONDON.

(Specially Reported for THE MEDICAL RECORD.)

GENTLEMEN: When your Professor of Surgery, Dr. Dennis, invited me to lecture to you, I asked to be excused because I felt that I had nothing ready worthy of your special notice. But he took away my objection by choosing a subject for me, and therefore I ask you to regard my presence here, and also whatever I may say, as being under his responsibility and not mine. The subject which Dr. Dennis chose for me, one which could not possibly be disposed of satisfactorily in a single lecture, is of very great interest, of very wide application, and one which I feel a great hesitation in speaking of at all, because in this country, perhaps more than in any other with which I am acquainted, the experience of surgeons with gunshot wounds has been very large and of an unusual kind. In your great civil war surgeons acquired a knowledge in this matter which is not exceeded by that possessed by surgeons in any other part of the world. Therefore it seems somewhat like, as we call it in our country, carrying coals to Newcastle, for me to speak upon this subject at all. The results of the experience which your surgeons have gained are embodied in those volumes coming from the Surgeon-General's office, which I may say for magnificence, for completeness of detail, and for abundance of illustrations, are equalled nowhere else in the world. The other day I had the pleasure and the advantage of visiting that volume of the war at the Medical Museum under the guidance of your distinguished countryman Dr. Billings, and there I saw abundantly illustrated, with the greatest detail, every form and kind of gunshot injury. There is enough material there to stock a dozen museums. I thought, therefore, that this was neither the time nor the place, altogether fitting, for a general discussion of surgical matters in time of war. Possibly, however, you may be somewhat interested in a few remarks which I may make regarding my personal experience during the time of the war between France and Germany, which took place some twelve years ago.

I speak not my own opinion, but that which has often been expressed by very competent authorities, of the work accomplished by that volunteer organization of which I had the honor to be a member during the Franco-Prussian war. It was superior both in quality and quantity to that done by any other voluntary organization, and there were many from different countries. I need scarcely have said this when I state that at the head of that ambulance corps was placed a man who is known not only in this country, but all over the world, as a surgeon of ingenuity, of device, of fertility of resource equalled by few; a man whose character is loved by every one who knows him—Dr. Marion Sims. One afternoon we received orders at Paris to reach, as soon as possible, the scene of action between the contending armies at a once important place, fortified by one of the

greatest engineers of his day. When we reached the town, the hostile armies not being far distant, it was striking to notice that, although almost within hearing distance of war, there was not in the whole place a single soldier to be seen; not a single man in military uniform. The only doctor whom I found was a fine old French army surgeon, who entreated us to remain where we were, saying we should have plenty of work to do, and the result showed him to be right. But we were bound to push on, and we tried our best to do so. After spending the night on some benches at a railroad station, the next morning we accepted an offer, previously made, of a hospital pavilion containing four hundred beds, and situated on the ramparts of the town, overlooking the whole scene of action as far as the eye could reach. The beds were equipped fairly enough, although the cleanliness might have been a little more perfect. In the morning the battle began, and continued all day, and soon our wounded came in in very large numbers. The beds were full in a short time with the most serious of cases. Not only were the beds filled, but the wounded occupied the stair-steps, the floor, and every possible nook and corner; all the houses in the town and about the town were full of wounded soldiers. There were several thousand wounded men, the result of the day's fight. I scarcely need say that all that we could do was but very little amidst so much suffering. There was work for ten times, yes, a hundred times, as many as we, but all that we could do we tried to do to the best of our abilities. All sorts of operations had to be done continuously by day and by night. We were blessed, fortunately, with a certain amount of equipments, as we had drugs, appliances of various kinds, and we had the advantage of a hospital placed in the front line of battle. All that day, while the battle was raging, we were in the very foremost of it. The shells exploding and whizzing around our heads was not, I assure you, very agreeable when about to perform an operation. Once in a while a shell would explode and strike the pavilion, but it was evident that the fire was not directed purposely against us. Had it been, I think we should have been knocked into a cocked hat without the slightest doubt. Indeed, years later I met in Berlin the officer who had been in charge at this point of action, and he told me that he saw our flag, and avoided as far as possible firing in that direction. This gentleman was a son of that distinguished surgeon, both in military and civil practice, Von Langenbeck.

Well, gentlemen, we had certainly a large number of operations to perform; and operations upon wounds of all kinds. There were fractures of all sorts to treat. Later on we had secondary operations and resections to perform. Opportunities such as these are of course rarely given to any one, and we tried to avail ourselves of the opportunities as far as we could. The operations were performed in accordance with our then recognized best methods, and the results were affected by the demoralized condition of the French troops from defeat in battle. We had, of course, very inadequate nourishment for them, a condition of things which lasted for some time. At first we had an insufficiency of appliances, but this did not last long, for supplies of all kinds soon came pouring in upon us. We had not the advantages of antiseptic surgery, which you at present, and in time of peace possess, and we of course had the sad fortune, in spite of all our efforts, to see patients upon whom we had performed am-

putations, treated compound fractures, or operated even for simple wounds, die one after another, and often from blood-poisoning.

RESECTIONS IN MILITARY SURGERY.

I have said that we came later to perform a certain number of resections, and upon this subject I will make a few remarks. The great Langenbeck, who had greater experience in military surgery than any other surgeon, I believe, says that resections are not satisfactory; that they are very dangerous to life, and certainly the results, so far as function is concerned, are, unfortunately, even less favorable. Many of the resections which I had to perform were upon soldiers sent in later, after the rush, and I may say that very satisfactory results in some instances were obtained. In the second period after the injury, after inflammation has subsided, there are reasons why such operations should be more favorably performed, both as regards use and physiological function. In the first place, in comminuted fracture, we find often, after the second period, that certain of the fragments have recovered themselves; they are not detached sufficiently to lose all vitality, and therefore we are able to ascertain, with greater accuracy than at first, the proper limitation of the operation. We are thus enabled possibly to decide upon a partial operation. I think that the experience of surgeons teaches us that in partial operations we should do just what is sufficient and no more, and that such a course is not only less dangerous to the patient's life, but is also often followed by much more satisfactory results. For at that period the periosteum has become thicker, it has greater vascularity, it is easily detached from the bone, and above all it possesses a greater degree of osteo-genetic function; whilst immediately after the injury the periosteum is exceedingly thin, is very difficult to detach, it tears while detaching it, and in addition it possesses very little osteo-genetic power. So these are reasons, I think, which show that excision after gunshot injury of bones can be more safely and more wisely performed at this period than immediately after the receipt of the injury.

I will not weary you with a recitation of cases, but I wish simply to give you an account of one or two which will illustrate the point in question. I need not dwell upon the fact of the greater risk which attends these operations upon the joints, or the reasons why resections are more applicable to the wrist and shoulder than to the ankle and the knee. The knee and hip are least fitted for an operation of this kind, as is shown by the experience of the civil war in this country, and since then by wars in other countries. In the case of the ankle-joint, showing how complete may be the function after shattering and subsequent excision, I will mention the case of a young German officer of noble rank, under the care of Professor Langenbeck. The result of the operation was not only recovery, but such complete reproduction of the parts excised that apparently the limb on one side was as well formed as that on the other. The function was so perfect that the officer was afterward able to walk to the top of Mount Rosa, one of the highest peaks of the Alps, a peak which the larger proportion of you would not care to ascend.

Another case, which came under my own care, I will mention as it is somewhat unique. Ten or eleven days after the battle of which I have been speaking, a French chasseur was carried to the hospital. The man's wounds were very extensive, and were evidence of his great bravery. The entire shoulder and arm were severely injured, the shoulder-joint was opened into in every direction, the deltoid was torn away, the radius and the ulna were implicated, and I was obliged when I saw the man, which was not until suppuration had set in, to resect a portion of the humerus and also of the radius, and about three inches of the ulna. The patient finally recovered after a very severe attack of septic poisoning. I have heard from him once every year since. There was nearly

complete reproduction of the shaft of the humerus, four inches of the upper and one inch of the lower portion of which had been excised, besides a considerable portion of the remainder being in a necrosed condition. There was such complete reproduction of the lower end that the condyles are quite perfectly formed. The man is now able to dig with the spade, to roll casks, to do all ordinary work, although he is of course unable to raise the arm perfectly because of the injury done the deltoid. The family physician described the appearance of the parts as apparently entirely normal, and his description was perfectly correct, as I afterward had opportunity to verify.

Speaking of injuries to the upper extremity, I would call attention to the triangular pad invented by Stromeier, a man of great experience in military surgery, who considered it more useful than any other one instrument or piece of apparatus. By means of this splint any wound of the upper extremity can be treated with the greatest comfort to the patient, and with the greatest prospects of success. It is carried between the arm and the body, and may be used as a splint to bind the parts together in almost any injury of the upper extremity.

AVOID PROBING GUNSHOT WOUNDS.

Another thing which I think I have learned in my experience with gunshot injuries, and one which I should like also to teach you, is to avoid unnecessary probing, or to avoid probing altogether as far as you may. I see from the manner in which you receive this remark that it requires little emphasis from me, but I think it cannot be too strongly stated that the bullet, or what has become of it, is really of secondary importance in the treatment of gunshot injuries. Usually, the first inquiry of the individual wounded is, what has become of the bullet? If it remain in the body, he asks to be relieved of it, and sometimes the surgeon, in his enthusiasm, makes a very considerable effort to fulfil the patient's desire. One instrument after another is introduced, until the end of the list is reached, which is a long one, for every sort of device and appliance has been invented for this purpose. I know by repeated experience how difficult it is to discriminate between a piece of lead or an exposed surface of bone, or even the edge of fascia or a tendon, and if the surgeon fails with the probe, as he often does, one forceps after another is then introduced, and the limb is almost removed piecemeal in the determined efforts to find the foreign body. Septic matter is necessarily introduced with the instruments and the surgeon's finger, and thus a trivial wound may ultimately result, from septic suppuration, in the death of the patient or loss of function of the member. Experience shows us how constantly bullets become impacted or lodged in parts of the body and remain there for years without causing any damage at all. No doubt it is not particularly desirable to have them remain if they can be easily taken away; but what I wish to insist upon is, that there is infinitely more damage capable of being done by the injudicious efforts of the surgeon in trying to remove the bullet than would be done by the presence of half a dozen bullets. In the museum at Washington, and in all museums, there are specimens of bullets lodged in the brain, in the lungs, in bones, etc., in some cases remaining there for years. In the museum at Washington I saw a specimen in which a bullet, entering near the knee, passed into the cartilage of the joint, penetrating almost entirely through it into the joint. The man, at the time of the receipt of this wound, also sustained a wound of the elbow, and he told the surgeon that a bullet had gone into the knee-joint. The surgeon fortunately did not believe him and let the knee alone, and the man lived for years afterward with perfect use of the limb, and at his death the bullet was found in the position mentioned. I might multiply examples going to show that bullets are often not so damaging if left in the

limb, while great damage may result from injudicious attempts to remove them.

PENETRATING GUNSHOT WOUNDS OF JOINTS.

In the Turko Russian war the advantage of this practice received one of the strongest illustrations possible. A hospital was established in which penetrating wounds of the joints were treated simply by sealing up the wound by some antiseptic method, and by immobilizing the joint completely. I quote from memory, not having the exact statistics at hand, when I say that in twenty-one cases of such wounds there were nineteen which recovered with the use of the limb. These were cases of undoubted penetrating wounds of the joint. If you can give such a series as that as compared with the results of former methods, by which I heard Langenbeck say that he did not believe a single case of penetrating wound of the knee-joint recovered in the whole duration of the Franco-Prussian war, you can see what an amazing stride has been made in the treatment of gunshot wounds. The distinguished surgeon, Stromeyer, states that he never probes or interferes in any way with gunshot fractures of the joint, but does his utmost to treat such cases by rest and antiseptics, and the published results of this method of treating fractures in his hands have been infinitely better than those obtained by any other surgeon. We know how common the opinion had been to consider that gunshot fracture of the femur necessitated amputation; and we now see on the other hand how surprisingly successful have been the results of the later method. I hope, gentlemen, that these remarks may lead you to reflect on the importance of the maxim from which Prof. Esmarch, of Kiel, preaches, which, translated from the Latin, means, do not injure, do not do damage.

GUNSHOT WOUNDS OF THE ABDOMEN.

There is one other subject to which I would like to refer, namely, the question of gunshot wounds of the abdomen. A short time since, my honored friend, Dr. Marion Sims, published some most interesting papers in which he advocated that these injuries should not simply be let alone, but that some effort should be made to save the patients from what would otherwise prove inevitable death. He proposed to open the abdominal cavity, search for the wounded intestine, and either excise or suture it, or treat it in the most appropriate manner, and then to cleanse the cavity and close the wound, and possibly recovery might follow. Now, there is everything in favor of such an attempt, I think. We now make exploratory abdominal operations every day. The abdominal cavity is opened without hesitation, under proper precautions, to see what is the matter inside. I think that almost every viscus of this cavity, except the liver, has been excised more or less successfully, in whole or in part. Part of the stomach, considerable stretches of the intestine, the uterus, etc., have been removed; and you all know with what wonderful success ovarian operations have been performed. Therefore there can be no just cause why such an operation as that suggested should not be performed in these otherwise certainly fatal cases. We know that there are great and various dangers attending the entrance of a bullet into the abdominal cavity; the danger of extravasation of blood, of fecal extravasation, etc., and the cases in which the ball passes through without injuring the intestine can only be very exceptional. Now, when patients have recovered after pouring out of urine into the abdominal cavity, have gone through the dangers of breaking up firm adhesions in the removal of ovarian cysts, etc., should we fold our hands and do nothing in cases of gunshot wounds of the abdomen?

Formerly there were many obstacles in the way of treating gunshot wounds in time of war according to approved antiseptic methods: the clumsiness of the material making it difficult of transportation, the use of the spray being considered a necessity, etc. But now the

spray may be dispensed with. We have antiseptic materials, iodoform, for instance, of small bulk compared with their strength, easy of transportation, and ever at hand. Add to these the fact that many wounds which formerly would have called for amputation are now treated by simply sealing them up with an antiseptic and maintaining rest, and I think, gentlemen, you may feel that you have a great future before you in military surgery. This belief is supported by the results achieved in the late war in Egypt. Although there were not a great many wounded during that campaign, yet on one occasion the number accumulated very rapidly, many of the cases calling for amputation. This expedition had gone out with the best possible equipment that money could purchase or experience devise. Every antiseptic most approved of, and every appliance which could be thought of, were at the disposal of our surgeons. The result was, and I speak again from memory, but I think I am correct in saying that out of four hundred and thirty-six wounded men thrown on the hands of our surgeons in a very brief period, there was not a single instance, throughout the entire campaign, of any form whatever of infectious disease; there was no erysipelas, and not a single case of pyæmia.

Gentlemen, after all, what is surgery? It is work for a man's hands, and the old chirurgien was the tool in the hands of other people. But is that the surgeon of to-day? No. He works with his hands, but he has got to work with his head and with his heart as well. Surgery is a fight with death, in which, unfortunately, the surgeon is often powerless; but never before in the history of surgery have the equipments of the surgeon been more complete, and never before have the victories which he has won been more glorious.

We speak of conservative surgery. I think it is a misapplied term, for is not all surgery conservative? If the surgeon has to amputate a crushed limb or remove a malignant tumor, is not that conservation? Is any surgeon not conservative in surgery? I think the word should be almost banished from our language as applied to this science.

The field of medicine is vast, and our best efforts will prove none too great when devoted to coping with the various human ills to which the different vocations in life expose us. The surgeon who will realize the best results is he who takes on the greater degree of appropriate knowledge and culture. While the field for the future is vast, human intelligence seems capable of growing with the requirements, and I feel assured that, as the surgeon of to-day is better able to grasp with the difficulties which he encounters than the surgeon of the past, so the surgeon of the future will be in advance of his brethren of the present, and his efforts to lessen the amount of human suffering will be crowned with a greater degree of success.

Gentlemen, I have but one word more to say in conclusion, and that is to express how deeply I appreciate the compliment in asking me to address you, and, however unworthily I have fulfilled my part of the undertaking, I thank you for your courtesy in so patiently listening to me. I am now on the point of returning to my own country, and I return carrying with me the happiest recollections. The courtesy and hospitality which have everywhere been shown me I can but regard as a great compliment on the part of the highly cultured portion of this community. In my travels here I have heard expressed but one sentiment toward us, a sentiment of good-will and good feeling, and I assure you that this feeling is reciprocated by us at home.

AN EPIDEMIC OF DIPHTHERIA has appeared in the Blind Asylum at Batavia, N. Y., most of the pupils have been sent away. A large number of deaths from diphtheria have occurred, it is said, in the village, which is wretchedly drained.

Original Articles.

A SIMPLIFIED EVACUATOR FOR THE REMOVAL OF DEBRIS FROM THE BLADDER AFTER LITHOTRITY.

By F. N. OTIS, M.D.,

CLINICAL PROFESSOR GENITO-URINARY DISEASES IN THE COLLEGE OF PHYSICIANS AND SURGEONS, ETC., NEW YORK.

THE revolution which has occurred, in the mode of removing stone from the bladder, within the last five years, may now be said to be complete. The new method, first put into practice by Professor Bigelow, of Boston, whereby, as a rule, stones of any size and degree of hardness may be removed at a single sitting, has been formally and explicitly accepted, by the leading authorities, in Europe and America, as an illustrious advance in genito-urinary surgery, and has found successful imitators and enthusiastic advocates in every country. In presenting this new method, at the meeting of the International Medical Congress, held at London, England, in 1881, Dr. Bigelow briefly reviewed the methods previously in use, and as briefly alluded to his own. He said, "From the days of Civiale to the year 1878, there was little change in the operation. The duration of a sitting, was as brief as the skill of the surgeon, stimulated by the fear of producing cystitis, could make it. Three minutes, or less, was the limit inculcated by standard books, and the teaching of specialists, and the use of anaesthesia was exceptional. At present anaesthetics are the rule. The instruments have been already modified, in an important manner, while the sittings often last half an hour, and have been successfully extended to three hours and more." In explaining the manner in which these important changes had been brought about, Professor Bigelow referred to the first instrument devised for the rapid evacuation of stone from the bladder after crushing. This was the invention of Sir Philip Crampton, in 1846. The apparatus consisted of a glass receiver, in form and size like a large soda-water bottle, from which, by means of an exhausting syringe he removed the air, and then applied it to a silver evacuating catheter, previously introduced into the bladder, into the cavity of which some ten or twelve ounces of water had been previously injected. On turning the tap, attached to the receiver, a powerful rush of water and calculous debris, through the catheter, took place. "This," says Sir Henry Thompson, "was found to be dangerously rough in its action and required to be so repeatedly charged that I desisted from its use."

FIG. 1.—Sir Philip Crampton's Evacuator.

This instrument was modified by Mr. Clover, of London, who substituted, for the glass receiver and the exhausting syringe, an india-rubber bottle placed behind a glass receiver. On compression of the elastic bottle, the necessary vacuum was formed, and the debris was deposited gently into the receiver. The first form of the receiver was a simple cylinder of glass, as in the accompanying cut, Fig. 2.

This instrument was subsequently modified by the addition of a vertical glass chamber for the prevention of a return of the debris into the bladder.

Professor Bigelow pays a merited tribute to Mr. Clover, whose instrument for evacuating calculous material from

the bladder, after lithotripsy, was the only one of practical value previous to his own.

He says, "Had Clover, whose catheter had a calibre of only 21 of the French standard (about 12 English), or Mercier, employed larger catheters (between 25 and 31

FIG. 2.—Mr. Clover's First Evacuator.

French—15 to 20 English) they might have evacuated the bladder completely! They would have found how little affected it was by a long operation, if no fragments were left behind, and that polished instruments were not injurious, while sharp fragments were. They would have discovered a tolerance, on the part of the bladder, wholly at variance with the traditions of half a century. Upon this tolerance modern lithotripsy is based.

"The new and essential instrument, is the large catheter (25 to 31), whether straight or curved. This is indispensable." Then follows a description of the evacuator of Professor Bigelow. It will at once be seen that there is an important hiatus, between the old, inefficient instrument of Clover, and "the new and essential instrument" of Bigelow, and that is, an explanation of the reason why the larger instrument was not constructed and used by Clover, and thus have secured, at once, the later advantages of modern lithotripsy. In order to complete the history of this important advance in genito-urinary surgery, I may, perhaps, be permitted to state, that it was in consequence of the fact that all anatomical and surgical authorities, previous to the invention of Clover's evacuator, and up to the year 1874, taught that the normal calibre of the urethra did not exceed 21 mm. in circumference. In accordance with that teaching, Mr. Clover could not use an evacuating tube of more than 21 mm. in circumference, hence, its capacity for evacuation of calculous debris, was so limited as to render its use of comparatively little value.

After a careful practical study of the dimensions of the urethra, extending over several years, and finally, through the invention of the urethrametre in 1874, I discovered, and was able publicly to demonstrate, an average normal urethral calibre of at least 32 mm. circumference.

Professor Bigelow, in his earliest monograph on "Litholapaxy, or Rapid Lithotripsy with Evacuation," page 11, says: "Whether or not we adopt the view of Otis, that the average capacity of the normal urethra is about thirty-three of Charrière, there can be no question that it will admit a much larger tube than that commonly attached to either Clover's or the French apparatus."

FIG. 3.—Clover's Improved Evacuator. A, india-rubber air-chamber; B, glass receiver; C, tube projecting into receiver; D, junction between evacuating catheter and suction apparatus. Size of evacuating catheter 12—English—equal to 21 mm. in circumference.

While fully accepting the truth of this statement, it seems to me proper to suggest that, it is not a question of "Whether or not we accept the view of Otis," etc. The fact stated, "that there can be no question that the urethra will admit a much larger tube than that commonly attached to either Clover's or the French apparatus, *was not established nor claimed*, prior to my demonstrations in America and Europe in 1874 and 1875."¹

Dr. Bigelow, in his paper before the International Congress, previously alluded to, thus vigorously states the result of a failure to appreciate the true or normal calibre of the male urethra. There he says: "*The small size of the previous evacuating catheters delayed surgical progress for nearly half a century.*"

By thus explaining why the use of an evacuating tube from 25 to 32 mm. in circumference, was not adopted by Clover and Mercier, the hiatus in the history of this important advance in surgery, previously alluded to, is completely filled.

Professor Bigelow, in his report to the International Congress, modestly disclaimed any credit in the operation, except in the use of the large evacuating tube, and assumed that Clover and Mercier, certainly would have discovered the tolerance on the part of the bladder, upon which he claims "modern lithotripsy is based."²

It is true, that Professor Bigelow did not discover the tolerance of the bladder to instrumental interference. This was previously well known. On March 3, 1876, and thus over two years previous to the publication of his brochure on "Litholapaxy," I was called upon by Dr. Fred. P. Mann, of Brooklyn, to remove a calculus from the bladder of a lady sixty-four years of age. With the assistance of my associate Dr. Bangs, and Dr. Mann, the urethra, which easily admitted 30 under ether, was dilated up to 45. A forceps was introduced, the stone (a phosphatic one) was crushed, and the debris washed out with Clover's apparatus attached to a 30 silver, open-end, evacuating tube. On subsequently examining the walls of the bladder with the finger, they were found coated with calculous material, which, by the aid of a scoop, my finger, and repeated washings, I was enabled completely to remove. The time, during which the bladder was subjected to this necessary procedure, was just one hour and ten minutes.

The patient rallied quickly from the anaesthesia; the operation was not followed by the slightest constitutional disturbance, and she made a perfect recovery, and is at the present writing alive and in good health.

November 6, 1877, I was called to Sag Harbor to see a case of supposed urethral stricture with ulceration of the bladder. The patient had been confined to his bed for more than a year. On examination, I found a stone in the bladder, and operating by Dolbeau's method I passed a forceps through the perineal opening, crushed and removed a calculus, the debris of which, filled a large goblet. The calculus was so large, that I was nearly an hour in crushing off the sides of the stone, before it could be brought fairly within the jaws of the forceps. After this, the operation was speedily finished, but, with the necessary instrumental interference within the bladder, and the subsequent manipulations for cleansing it, from the commencement of the crushing, to complete evacuation, the time was an hour and a quarter. No local trouble re-

sulted from this prolonged operative interference within the bladder. The patient made a perfectly satisfactory recovery under the care of Dr. Rodgers, of Sag Harbor.

I am sure that many surgeons have experiences, practically equivalent to the foregoing, antedating the operation of litholapaxy by many years. And thus I claim, that Professor Bigelow did not *discover* the tolerance of the human bladder to prolonged instrumental interference. He did much more—he utilized the knowledge which he in common with other surgeons possessed. He had the inspiration to conceive of its value as a factor in a great life-saving operation. He seized the demonstration of an average urethral calibre of 32 mm. in circumference. He joined it with his knowledge of the toleration of the bladder to legitimate surgical procedures, and *litholapaxy* was born. He had the courage, the surgical knowledge, the skill, the inventive mechanical genius, and the perseverance to carry it, *vi et armis*, to a successful maturity, *thus finally achieving one of the most brilliant surgical triumphs of modern times.*

The size of the evacuating tube has been shown by Professor Bigelow to be the most important factor in the operation of litholapaxy. The smallest calibre to be really efficient and satisfactory may be fixed at 27 F., and the largest affording all desirable facility in evacuating the debris may be fixed at 32 F., which is less than the average normal calibre of the urethra by over one millimetre.

In a normal urethra, that is to say, one free from localized contractions or obstructions, it may be assumed that an evacuating tube of proper shape and corresponding size may, as a rule, be easily and safely passed through it, into the bladder. The normal calibre of any urethra may, in all cases, be safely assumed, from a measurement of the circumference of the penis.

After a careful experience on this point, in many hundred instances, I do not hesitate to claim, that the relation of the size of the urethra to the size of the penis, in any given case, is invariable, and that any variation from it is abnormal. I have never yet met with a single case, where the estimate of the calibre of a urethra, based upon this proportionate relation, has proved excessive.

This relation was formulated by me, in a table presented to the profession in 1875, as follows:

CIRCUMFERENCE MIDWAY OF THE PENIS.		
Of Penis.		Of Urethra.
3 inches, or 75 mm.		30 mm., or more.
3½ " " 81 mm.		32 mm., "
3¾ " " 87 mm.		34 mm., "]
4 " " 93 mm.		36 mm., "
4½ " " 100 mm.		38 mm., "
4¾ to 4½ " 105 to 112 mm.		40 mm., "

Now, while I have seen many cases, where the urethra was larger than that claimed in the foregoing table, I have never seen a single case where it was less. Whenever a full-sized instrument, selected in accordance with the proportionate relation, above claimed, did not easily traverse the urethra, then, the failure was always shown to be due, to localized contractions, either at the meatus, as the result of malformation, or pathological causes, or from easily recognized stricture at some deeper point in the canal. Obstructions resulting from prostatic enlargement should always be respected, and in such cases *the smallest tube which will be efficient in removing the debris* should be used. This, because all forcible interference with the parts thus diseased, is to be avoided as much as is possible. All localized contractions of the urethra, should be removed before the operation of litholapaxy. Contractions at the meatus, should be divided, and allowed to heal, before operation for litholapaxy. The chief dangers of litholapaxy, reside in the injuries to the deep urethra, during the operation—hence the urethra should be put in the best possible condition, throughout, before the operation is attempted. Time should always be allowed for complete healing of the wounds resulting from preliminary division of the meatus,

² Trans. Int. Cong., vol. ii., p. 293.

or of deeper contractions, before the operation of litholapaxy is attempted. In this way any hemorrhage, resulting during the operation, will be referred to its real cause, and the operator will be relieved from the embarrassment of a hemorrhage from the urethra, resulting from division of the meatus, or deeper stricture, at the time of operation, which could not then be quickly differentiated from hemorrhage produced by injury of the bladder, in the process of crushing. Civiale was in the habit of dividing the meatus and allowing the wound to heal, before attempting the operation of crushing the stone. In this way he discovered that many reflex irritations, simulating stone in the bladder, were due to the contraction of the meatus alone. Having, then, thoroughly cleared the urethra from all localized contractions, the operation of litholapaxy may be approached, with the greatest security against embarrassment from mechanical obstruction in the urethra.

The facility, and safety, with which the operation of removing the débris from the bladder, in litholapaxy, depends, in a very important degree, on the size and shape of the evacuating tube or catheter. Professor Bigelow recommends that the size shall not be below 25 mm. in circumference, nor above 31 mm. For my own part I have never yet met with a normal adult urethra of less than 28 mm. in circumference. Whenever, therefore, the urethra will not admit an evacuating tube of 26 or 27 mm. in circumference I do not hesitate to claim that stricture is present, either at the meatus, or at some deeper point, and, after verifying this claim by examination, to recommend restoration of the canal, by removal of the contractions by dilatation or by division, before operating, rather than to use an evacuating tube of a smaller size.

The difference of even 2 or 3 mm. in the size of an evacuating tube, when below 30 mm. in circumference, makes an astonishing difference in its evacuating capacity. For instance, in using the evacuating tube 30 mm. in circumference, twenty pressures of the bulb, at intervals of one and a half second, withdrew from the glass bottle (representing the bladder) and deposited in the receiver, 300 grains of crushed coral, which is almost identical in weight and mode of cleavage with mixed calculi. Whereas, under the same circumstances, with the same number of pressures of the bulb, and in exactly the same time, with an evacuating tube of 27 mm. circumference only 180 grains were deposited in the receiver. It may, I think, be confidently stated that in the absence of stricture, or congenital contraction of the meatus, or of prostatic enlargement, an evacuating tube, two or three sizes smaller than the normal urethra, according to estimate previously stated, may, as a rule, be easily and safely used.

Professor Bigelow uses, and recommends, the straight evacuating tube, in preference to the curved. The calculous débris finds its way through it, much more directly and easily, and while less liable to become clogged, it is more readily cleared. The only objection appears to be, the somewhat greater difficulty of introducing it into the bladder, especially in cases of enlargement of the prostate. I have modified the straight instrument of Professor Bigelow, by adding a small curved projection, which, with all the advantages of the former, I have found more easy of introduction, and preventing, in greater degree, the closure of the opening in the tube, from engagement of mucous membrane in it, during the process of evacuation. (See evacuating tubes in Fig. 12.)

Notwithstanding the statement of Professor Bigelow, already quoted, to the contrary, *something more than a large evacuating tube* was essential to the new operation. This was a more powerful evacuating apparatus than that of either Clover or Mercier. This lack was supplied by Professor Bigelow—thus finally enabling him to perfect his operation of “*rapid lithotripsy with evacuation*.”

His first apparatus consisted, simply, in a large, strong, india-rubber bulb, furnished with a glass receiver for the débris, and a tube at the opposite extremity for attachment to the evacuating tube. (See Fig. 5.)

This instrument was found perfectly efficient and came into general use, although it was open to the objection that fragments and débris, having been once withdrawn from the bladder, were again carried back into it by the return current. There was also the real, or theoretical, complaint, that, during its use, it permitted too free access of air into the bladder.

Sir Henry Thompson, of London, who was quick to recognize the great improvement of Bigelow's method over those previously followed, adopted Bigelow's procedure, and produced, in 1879, an evacuating apparatus differing from that of Professor Bigelow, in that the débris fell from the evacuating tube, directly into the receiver or trap, and that the connection of the tube with the bulb, was rigid and metallic, instead of by rubber tubing, and was filled, previous to use, through a funnel and stop-cock at its apex, instead of through the tubing. (See Fig. 6.) Efficient in Sir Henry's hands, it was exposed to the same objections that had been raised against Professor Bigelow's instrument. In 1880, in the third edition of his work on “*Practical Lith-*

FIG. 5.—Professor Bigelow's Original Evacuator. 1, elastic bulb; 2, curved rubber tube; 3, curved evacuating tube of silver; 4, straight evacuating tube, which is preferable to the curved one; 5, front view of same; 6, glass receptacle with bayonet joint for débris; 7, stand. (Tiemann & Co., New York.)

otomy and Lithotripsy,” page 186 (J. & A. Churchill, London), he presented the following modification of the apparatus (see Fig. 7), the advantages of which he claims are, that “the change in the position of the lower tap shortens the distance for the fragments to traverse, which thus reach the receiver by the shortest possible route. The current having less distance to travel, has thus more powerful action on the fragments, and consequently the aspiration is more perfectly made than it has hitherto been. The fragments enter, fall downward through the tube, and cannot mount again into the apparatus, in consequence of the projection of the tube into the glass receiver.” He also says, “for those who prefer a portion of flexible tube between the aspirator and the evacuating catheter¹ two inches thus interposed will insure freedom from any jar to the bladder in using the instrument, and will only lengthen the route *pro tanto*.” “For myself,” he concludes, “I prefer the absolutely direct and short-

¹ As in Professor Bigelow's original evacuator.

est route, having no more fear of hurting the bladder, with the inflexible evacuating catheter, than I have with the inflexible lithotrite."

Up to this point the evacuator of the great English lithotritist, appeared to possess the advantage over his American rival, in the more direct route for the débris, while the greater freedom from angles on this route (see

says: "I am not disposed to think that the utility of the instrument is thereby seriously impaired."

Professor Bigelow, nevertheless, began a series of experiments, with the view of increasing the excellence of his evacuator, addressed not only to excluding the air from it, during operation, but in preventing the débris from re-entering the bladder by the return current.¹

FIG. 6.—Sir Henry Thompson's Original Evacuator.

Fig. 5, page 482) seemed to promise at least equal efficiency for the latter.

Practically I had made use of Professor Bigelow's original instrument from an early date, with complete success in every instance, and without finding anything in its working, which appeared to decrease its efficiency, in any marked degree. Of it, as late as April, 1883, Mr. Harrison, of Liverpool, in his valuable brochure on

FIG. 7.—Sir Henry Thompson's Improved Evacuator, showing the mechanism of the taps through which the débris passes to the glass receiver.

In the improved instrument (see Fig. 8), heavy stop-cocks at DD, one attached to the evacuating tube and the other to that in connection with the bulb, and subsequently a catheter valve or strainer was interposed between the latter stop-cock and the bulb; also a tube F, guarded by a stop-cock at G, for refilling the bulb, if necessary, without withdrawing the evacuating catheter from the bladder.

FIG. 8.—Professor Bigelow's Evacuator, complete. Curves in the elastic tube make it less liable to flatten when bent. The hose is attached when it is needed. (From Bigelow, op. cit., page 297.)

lithotomy, lithotripsy, etc., writes of Professor Bigelow's evacuator thus: "After trying several modifications of it, I must express my satisfaction, so far, with the original instrument" (represented at page 482). He further says: "Exception has been taken to it on the grounds (1) that the trapping of the fragments is imperfect, (2) that the apparatus permits air to enter the bladder." Admitting the truth of these objections to some extent, he

FIG. 9.—The "Simplified Evacuator" and Stand. The catheter is prolonged, by a long tubular strainer, into the bulb. This makes a catheter-valve, though still advantageous, less necessary. An elastic ball or universal joint, with a small tubular strainer, is also substituted at the head of the catheter for the elastic tube, and makes the instrument shorter. The stand is here a retort stand. The bulb hangs firmly in a fork, and can be variously inclined.

This was subsequently modified by transferring the strainer to the body of the bulb and dispensing with the ball valve, as in Fig. 9.

In this, the route for débris is much shortened by the substitution of a universal joint in place of the tubing, and entering the bulb at its centre, instead of at its

¹ Transactions of the International Medical Congress, 1881, vol. ii., p. 293.

apex—on all these points more nearly approaching the evacuator of Sir Henry Thompson. The instrument, however, although more perfect in its working, was more complicated and expensive. Probably for this reason Professor Bigelow continued his efforts for a perfect and

Fig. 4 (Fig. 7, previous page) directly under the bottle, and may be influenced by currents, is removed to the front of it, and is perhaps less disturbed by the current which passes over the mouth of the receiver. . . . In neither Fig. 4 (Fig. 7, previous page) nor Fig. 5

FIG. 10.—Professor Bigelow's Evacuator, improved 1883.

more simple apparatus. These were signally successful, resulting, during the early part of the present year, in the instrument represented in the above sketch. In this the route for the *débris* is again greatly shortened.

(Fig. 11, above shown) is any stand required, and the connection with the bladder, is the shortest and simplest possible." The connection of the aspirator with the bladder, is also cut off in both instruments by the taps "T".

FIG. 11.—Sir Henry Thompson's latest Evacuator, modified by Weiss.

Notwithstanding their excellence in other respects, the weight and size of the different evacuators had often occurred to me as an objection, as well as their necessary expense, a good modern instrument costing about thirty dollars. After a careful experimental study of the matter, bearing in mind the excellent points of all the instruments in use for this purpose, the plan of a new instrument was evolved by me, and elaborated by the surgical cutlers, Messrs. George Tiemann & Co. It consists of a strong annealed glass bulb, A, two inches in diameter, the reservoir, into one side of which a metal tube, B, forty mm. in circumference, curving down to its lowest part, is inserted. This is connected to the evacuating catheter C by the india-rubber tube; attached to the floor of the reservoir by a bayonet-joint, E, is a short, strong, glass bottle, F, the receiver. On the side of the bulb, opposite the tube connecting with

FIG. 12.—The Author's Simplified Evacuator.

The return of *débris* to the bladder, is prevented by the strainer, which is here prolonged into the bulb at an acute angle. The movable joint is dispensed with, and probably, for the reasons given by Sir Henry Thompson on page 482, the connection with the bulb, is without an intervening flexible tube. I have used this on a single occasion, and its operation was perfect. I felt satisfied that for this form of instrument it was the most simple, direct, and efficient in action of any that had been devised. In the meantime, Sir Henry Thompson's improved evacuator, had been modified, at the suggestion of Messrs. Weiss & Son, surgical cutlers, of London, in order to carry out more perfectly one of the conditions for a perfect evacuator previously insisted on by Sir Henry Thompson, viz., to secure the shortest possible route for the passage of *débris* from the bladder to the receiver. This modification is shown in the appended woodcut (Fig. 11). "This," says Sir Henry, "is identical with Fig. 4 (as represented in Fig. 7 on previous page) in every particular, except that the cylindrical receiver which is in

evacuating catheter C by the india-rubber tube; attached to the floor of the reservoir by a bayonet-joint, E, is a short, strong, glass bottle, F, the receiver. On the side of the bulb, opposite the tube connecting with

FIG. 13.—The same reversed for filling.

the evacuating catheter, is another metal tube (at G) curving upward to near the top of the bulb A. This is connected by another flexible tube, H, with a strong india-rubber bulb, I, constituting an independent air-chamber. A stop-cock at the extremity of the flexible

tube permits the removal of the catheter without leakage from the reservoir A. The capacity of the reservoir A is just four fluid ounces, that of the receiver F one and one half ounce. To put the instrument in operation it is necessary, first, to shut the stop-cock, then disconnecting the receiver F from the reservoir A, and reversing the latter, so that its opening looks directly upward, with a small pitcher, or cup, fill it with water to the brim, requiring just two ounces.

Then, with the reservoir still in the same position, attach the receiver F (see Fig. 13). Return the instrument to its upright position and it is ready to be attached to the evacuating catheter, previously introduced into the bladder. Or the instrument, in the position shown, may be emptied of the contained air by firm compression of the bulb I, and the evacuating catheter placed in a vessel containing sufficient water, when by removing the pressure the instrument fills instantly and is then ready for use.

Directions for operating, the reservoir having been filled as above shown.—The evacuating catheter having been well oiled and carefully introduced into the bladder, the contained urine is evacuated and six to eight ounces of tepid water are introduced into the bladder. The evacuating catheter is then attached to the evacuator. Gentle pressure of the bulb—sufficient to displace one-third to one-half its contained air—drives a current of water into the bladder and produces the necessary vacuum. The returning current from the bladder brings a portion of its contained water, and with it the calculous debris. This is quietly, quickly, and certainly deposited into the receiver, from which there is no possibility of return into the bladder. Repeating the pressure on the bulb at intervals of two or three seconds, as long as the fragments are seen to fall into the receiver, the catheter, the point of which has been in contact with the most dependent portion of the bladder, is then withdrawn a little and gently moved about, in order that floating or reluctant fragments may find access to it, and the rhythmic pressure of the bulb is continued until no more debris is seen to fall into the receiver.

If, then, there are evidences that calculous material still remains in the bladder after removal of the evacuating catheter the crushing is renewed, after which the same operation for removal of the debris is repeated, and so on until the stone is completely removed.

In order to show how completely the debris is removed from the influence of the current which returns to the bladder, a colored solution may be placed in a bottle, the receiver filled to the brim with pure water or glycerine, and attached to the reservoir. Pressure of the bulb drives the colored solution into the reservoir without materially coloring the water in the receiver, thus showing that the current is between the mouth of the evacuating tube emptying into the reservoir, and that of the independent air-chamber, placing the receiver out of the influence of the current; consequently the debris drops quietly into the receiver and is there retained.

A MEDICAL HERO.—Says Dr. Parvin: How many a surgeon, after performing tracheotomy in a case of diphtheria, has found the tube obstructed, his patient in peril of instant death, and has applied his mouth to the tube and removed the obstruction, saving his patient, it may be, but killing himself! When the Alabama was hopelessly disabled by the well-directed shots of the Kearsarge, the gallant surgeon, Lewellyn, got his wounded men in the only two boats left, but, though urged, refused to enter either of them, lest, by overloading, the safety of his patients might be imperilled, and went down with the ill-fated ship to sudden death, but to an immortal memory.

DIGITALIN causes a decrease in the total work of the heart (of frogs and turtles), according to Messrs. Donaldson and Stevens.

THE ARCHITECTURE AND FUNCTIONS OF THE CEREBELLUM.¹

By AMBROSE L. RANNEY, M.D.,

NEW YORK.

(Continued from p. 452.)

If you study the *fourth ventricle*, the exposed portion of this tract will be seen to constitute the lateral boundary walls of that cavity (*processus e cerebello ad testes*), with the so-called "valve of Vieussens" (*velum medullary anterius*) enclosed between them. The latter formation deserves special notice in this connection.

The *processus cerebelli ad cerebrum* itself is by no means free from admixture of foreign elements during its passage from the cerebrum to the cerebellum, the details of which I have just given. At the level of origin of the fifth cranial nerve (*trigeminus*) fibres from the cerebellum to the greater root of that nerve can be demonstrated as fasciculi which in part cover it and in part traverse it. It is also traversed, at a lower plane, by fasciculi destined to belong to the eighth cranial nerve (*auditory*).

Valve of Vieussens.—In this commissural band (the medullary velum) three different systems of fibres lie interwoven: 1. The great mass of its substance is composed of bundles of fibres derived from the frenulum. 2. The decussating fibres of the fourth cranial nerve (*trochlearis*), which are grouped at the anterior extremity of the valve into bundles of extreme thickness, are inter-twined transversely with the fasciculi of the frenulum. 3. Certain longitudinal fibres may be demonstrated which can be traced to the superior vermiform process of the cerebellum. The course of these fibres is peculiar. They decussate before leaving the superior vermiform process; they then traverse the valve of Vieussens almost to the lower border of the corpus quadrigeminum; at this point, they double upon themselves, describing curves whose convexity looks upward; finally, they join the inferior lamina of the lemniscus at its posterior bundle, and pass onward with the latter, in the posterior division of the pons Varolii, to the spinal cord.

Processus cerebelli ad pontem (middle peduncle of cerebellum).—When the general architecture of the cerebro-spinal axis was under consideration,² the relation of the cerebellum to certain fibres which helped to form the "basis cruris" of Meynert (*crusta cruris*) was touched upon, as an anatomical explanation of the fact that the number of fibres of the middle projection system suffered an apparent decrease during their passage through the pons Varolii. It was then stated that some of the efferent fibres of the corpus striatum probably left the direct tract of the projection system within the region of the pons, and passed to the cerebellum. Some points pertaining to the physiological importance of these fibres were also mentioned in connection with my description of the corpus striatum. It has, moreover, been stated, in previous lectures, that the region of the pons contained certain *transverse fibres* connected with the cerebellum, which interlaced with the fibres of the cerebral projection tracts, and were probably more or less intimately associated with the nodal masses of gray matter found in that region. Some of these fibres are unquestionably commissural in character, serving to unite homologous regions of the cerebellar hemispheres; others probably serve to unite the hemispheres of the cerebellum with the gray matter of the crus of the opposite side. In man the pons is long, because the crusta cruris is developed in proportion to the size of the cerebral lobes; in animals it becomes shorter in proportion to the decrease in size of the cerebellum. The interlacement of the fibres of the projection system with those of the "*processus cerebelli ad pontem*" occupies the region of the pons and the upper half of the medulla (Meynert). It is somewhat curious to observe that the lateral regions of the cerebellum keep pace

¹ A part of a course of lectures delivered before the students of the University of the City of New York.

² See article by the author in the New York Medical Journal, April, 1883.

in their development with the cerebral lobes, and the "*nucleus dentatus*" of the cerebellum is developed in direct proportion to that of the olivary bodies of the medulla oblongata.

Cross sections of the region of the pons reveal the fact that the transverse fibres of the *processus cerebelli ad pontem* may be divided into *three sets*, as follows: 1, a superficial layer; 2, fibres which interlace with longitudinal fibres escaping from the crus; 3, a deep-seated layer. The superficial and deep layers appear to be perfectly independent of any association with the fibres which belong to the middle projection system of the cerebrum (those of the *crusta* and *tegmenum cruris*). Meynert, however, brings forward certain reasons, based upon a minute study of the general relations of these layers, which apparently lend support to the view that the fibres of these strata are in communication with nerve-cells embedded in the pons, that certain crural fibres are likewise joined to these cells, and that the two sets of fibres are thus brought into communication with each other. He states his conclusion as follows:

"Each fasciculus of the *basis cruris cerebri* that terminates in either side of the anterior division of the pons is represented in the *cerebellar hemisphere of the opposite side* by *two fasciculi*, one of which runs with the superficial, the other with the deep stratum of the transverse system of fibres from the point of their connection with the crural fasciculus into the *processus cerebelli ad pontem* of the opposite side."

Processus cerebelli ad medullam (restiform body, inferior peduncle of the cerebellum).—A complete description of this important bundle properly belongs to a subsequent article, which shall treat of the architecture of the medulla oblongata. It is a round and prominent cord, which passes directly into the corresponding hemisphere of the cerebellum. The fibres of the lateral cerebellar tract and the arched fibres of the medulla oblongata can positively be traced from it to the substance of the cerebellum. The distribution of some other bundles found within it is still unsettled. The fibres of the restiform body probably terminate either in the *corpus dentatum* or the cortex of the posterior surface of the hemisphere.

Relations of the cerebellum to cranial nerves.—At various times, articles have appeared which tend to show that the fibres of origin of some of the cranial nerves can be traced to the cerebellum. When a positive demonstration of the statements made by some of the later anatomists can be furnished, much light will be shed upon the functions of this ganglion. There seems to be every reason, at present, to believe that the *auditory nerve* can be traced to the cerebellum after its fibres have passed through the auditory nucleus; and the number of such fibres appears to be in excess of those actually comprised within the nerve itself. In this respect a strong analogy is presented between the auditory fibres and those of the *corona radiata* of the cerebrum, which are themselves more numerous than those of the *crus*, although they appear to be a direct continuation of them (as was stated when the basal ganglia of the cerebrum were under consideration). The opinion advanced by Spitzka, that the fibres of the sensory root of the *trigeminus* can be also traced to the cerebellum, lacks positive confirmation as yet; and the same remark might apply with equal justness to the views of those observers who believe that the *third*, *fourth*, and *tenth cranial nerves* have a direct association with that ganglion. There are physiological experiments on record which seem to sustain all of these views as well as others which combat them. These will be explained later. The proof, however, that fibres of the nerves mentioned can be actually demonstrated within the substance of the cerebellum, cannot, to my mind, be considered as final, although some neurologists are inclining more strongly of late toward that belief.

The functions of the cerebellum.—From the date of Flourens' first experiments upon the cerebellum of ani-

mals down to the present time, neither sensibility nor marked excitability seems to have been demonstrated as attributes of this ganglion. Animals which have suffered extreme mutilation of the cerebellum experience no apparent pain, nor does direct irritation of that ganglion result in pain or convulsive movements. The opinion that the cerebellum is incapable of direct stimulation, which is still held by some physiologists, seems to be confuted, however, by the experiments of Budge, who observed that movements of the testicle and *vas deferens* occurred in the male, and of the horn of the uterus and the Fallopian tubes in the female, when direct irritation of the cerebellum was employed. The same observer produced movements in the stomach and *œsophagus* by means of cerebellar stimulation.

The widest differences in opinion exist among physiologists and neurologists regarding the functions of this ganglion, since the most positive and direct results of experimentation upon animals are apparently contradicted by pathological observations upon the human subject. There is one conclusion, however, in which most physiological observers, since the date of Flourens' original experiments, concur, viz., that the cerebellum, in some way, influences to a marked degree the *co-ordination of muscular movements*. This is very apparent in birds deprived of the cerebellum in whole or in part; since the power of performing definite and regular acts of locomotion is lost, although the animal is not paralyzed. If laid upon the back, the bird cannot recover itself, in spite of exhausting efforts to do so. If placed upon the feet, it executes sudden and disordered movements, and shows an agitation which is in marked contrast to the stupor which follows a removal of the cerebral lobes; it can still see and hear, feel pain, exhibit evidences of volition in its endeavors to avoid a threatening blow, and apparently it possesses normal intellectual faculties. Life is not particularly endangered by these experiments, as some of Flourens' birds lived several months, although severe hemorrhage and injury to the medulla may sometimes occur in performing them. If only portions of the cerebellum are removed, the animal appears to *slowly regain* its power of co-ordination of muscular movement; this fact may tend to explain the absence of marked symptoms in the human subject, in spite of extensive lesions.

When Andral published a collection of ninety-three cases in which well-marked lesions of the cerebellum were found after death, and announced that only one sustained the view that the cerebellum governed co-ordination of movement, physiologists were startled and made to doubt the positiveness of their own conclusions. These cases were, however, carefully analyzed by Flint, who entered into a lengthy argument to prove that the cases cited did not warrant the conclusion of their compiler. Nothnagel published in 1878 the results of his analysis of more than two hundred and fifty cases of cerebellar disease. He is inclined to admit the existence of cerebellar ataxia (which he describes as a perversion of equilibrium resembling alcoholic intoxication) as characteristic of cerebellar disease, but he thinks that the *superior vermiform process* is especially liable to produce it, if extensively affected. In the majority of instances the upper extremities remain free from inco-ordination. Subjects in whom cerebellar ataxia is well marked stand, as a rule, with their feet well apart, in order, as it were, to increase their base of support; they sway from side to side and titubate; the toes are seen to be in active motion if the patient stands barefooted; in walking, the body sways and the heel and ball of the foot are brought into contact with the ground irregularly; the ataxic symptoms may and may not be increased by closing the eyes; in the recumbent posture all these ataxic manifestations entirely disappear.

The *tentorium cerebelli*, which serves to separate the cerebellum from the posterior cerebral lobes, and which in some animals is a portion of bone, appears to have

a clinical bearing upon the development of lesions of the cerebellum, since it seems to favor their growth in a forward and downward direction. It is important for you to bear this in mind when the effects of local destruction of this ganglion are under consideration, as well as the fact that an experimental or pathological lesion seldom, if ever, involves all the numerous nerve-tracts and centres which exist within this ganglion, but have different peripheral connections.

By recalling the important connections of the cerebellum with other parts of the brain and the spinal nerve-tracts, by means of its three crura, and bearing in mind also that the third, fourth, fifth, acoustic, and pneumogastric nerves may possibly have direct sources of origin within its substance (the proof of a relation with all of which, however, is still somewhat unsatisfactory¹), you can readily understand that the symptomatology of cerebellar lesions must, of necessity, be peculiarly involved and complex. The important organs which underlie the cerebellum (the corpora quadrigemina, the tegmentum cruris, and the medulla oblongata) are liable, furthermore, to be simultaneously affected, either by pressure or the extension of the disease to these parts. Within the first of these we probably have centres which govern the movements of the eyeball (Adamuck), and some decussating fibres of the nerve of sight (Charcot); in the second, a vasomotor centre, and possibly one which presides over convulsive movements (?) are believed by some authorities to exist; in the third we find the olivary bodies, which are connected with the cerebellum, and the various nuclei of origin of important cranial nerves.

FIG. 3.—A Diagram Designed to Show the Probable Connections of Certain Nerve-Tracts with the Different Portions of the Cerebellum.—B-B, the mesial line of the cerebellum; N.F., nucleus fastigii, situated in the worm N.D., nucleus dentatum, situated in the hemisphere; C.C., cerebellar cortex, covering the peripheral parts of the hemisphere; A.N., auditory nucleus, connected with the auditory nerve (A), and also with fibres which decussate and pass backward to become united with the nucleus fastigii and the nucleus dentatum; R.N., red nucleus of the tegmentum, connected with fibres springing from the dentate nucleus and the cerebellar cortex, and decussating before they reach the region of the red nucleus of the opposite side; V.P., vermiform process (worm), which contains the nucleus fastigii of either side within its substance, and gives origin to fibres of the trapezium from within its white or medullary substance; O.B., olivary body of one side of the medulla, connected with fibres passing to the dentate nucleus and cerebellar cortex; T, fibres of the trapezium, springing from the medulla and connected with the nucleus fastigii and the medullary substance of the worm; R.B., fibres of the restiform body (inferior peduncle of the cerebellum), connected with the olivary body and also with the cerebellar cortex, the dentate nucleus of the opposite side and the worm.

We are apparently justified, on anatomical grounds, in attributing the affections of *sight* which are so often observed in connection with lesions of the cerebellum to pressure upon the geniculate bodies, the corpora quadrigemina, or the fibres or nuclei of origin of the third, fourth, or sixth nerves. On similar grounds, the attacks of *nausea*, *vomiting*, *cardiac disturbances*, and *sudden death* may be attributed to the pressure of cerebellar lesions upon the nuclei of origin of the vagus nerve

within the floor of the fourth ventricle, resulting in either irritation or complete paralysis of that nerve. The *convulsive attacks*, which are occasionally observed in connection with cerebellar lesions, may perhaps be explained by pressure upon the convulsive centre of the tegmentum cruris; and the development of *hemiplegia* of an imperfect type, or of *general paralysis*, both of which have been reported as occurring from cerebellar disease, may be explained by a similar effect upon the direct motor tract of the cerebral projection system.

In direct antagonism to the results of Flourens' experiments, lesions of the cerebellum of the human race seem to be often associated with pain which predominates in the occipital region. In fact, the diagnosis of cerebellar disease is made chiefly on the predominant occipital pain (Brown-Séquard), with titubation and other peculiarities observed during the erect attitude of the patient. Exclusion of disease in adjoining regions must, however, always be made by the absence of symptoms before making a positive diagnosis; because occipital pain and titubation may both be often wanting, and the so-called "ataxic symptoms," when present, do not exist in the marked degree commonly met with in posterior spinal sclerosis. It is uncommon to find true ataxic jerking; and choreic movements and tremor are usually absent. The want of harmony between antagonistic groups of muscles is also wanting.

An attempt has been made to connect the cerebellum with the generative function, but physiological experiment has apparently demonstrated its fallacy. A rooster, in whom the cerebellum had been removed, attempted to mount a hen eight months afterward, and failed apparently only on account of the lack of power to co-ordinate his muscles (Flourens). There seems to be no well-authenticated instance where the sexual instinct has been destroyed in animals by removal of the cerebellum. Leuret found that the cerebellum was even larger in geldings than in stallions or mares. Among the numerous cases of disease of this ganglion to which we have referred, some suffered from a marked excitation of the sexual apparatus, while others had a well-marked atrophy of the genital organs and impotency. There are many physiological as well as pathological facts which tend to refute the idea that the cerebellum is the seat of sexual instinct, and to locate it in the lumbar region of the spinal cord; still it cannot be denied that numerous cases, on the other hand, seem to point to some connection between the cerebellum and that centre, or the organs of generation, in the human subject.

When the corpus striatum was discussed,¹ it was stated that the superior peduncles of the cerebellum could be traced to the so-called "yellow nucleus" of the caudate portion of that ganglion. Luys considers that by means of these fibres the cerebellum is enabled to constantly reinforce the cells of the corpus striatum when they become exhausted, thus enabling them to exert their modifying effects upon all the motor impulses arising in the cerebral cortex which are forced to pass through them, as well as to manifest a peculiar automatism which the cells of the basal ganglia seem to possess. This theory of Luys does not differ markedly from that advanced by Mitchell, viz., that the cerebellum serves as a storehouse of nerve-force, which may be drawn by means of any of its peduncles when emergencies arise to demand it. Some interesting physiological experiments have been made, which seem to point to some intimate association between the cerebellum and the basal ganglia. We know that section of the middle peduncle of the cerebellum almost invariably gives rise to a peculiar "forced movement," the animal rolling rapidly round its own longitudinal axis, the rotation being commonly toward the side operated upon.² This is accompanied by a peculiar dancing and oscillation of the eyeballs, termed "nystagmus."

¹ The connection of the auditory nerve with the cerebellum is now quite generally accepted by neurologists.

² Journal of Nervous and Mental Diseases, January, 1883.

² Bechterew has lately shown that section of the olivary bodies has the same effect.

Now, Purkinje observed long ago that electric currents sent through the head from ear to ear produced the same movements of the eyeballs and a tendency toward the forced movement of rotation. The patient leans toward the anode, and objects spin before the eyes in the direction of the electric current. When the current is broken the objects revolve in an opposite direction, and the patient leans toward the cathode. Hitzig has shown that neither the vertigo nor the movements of the patient's body depend upon the objects perceived by vision, since the same phenomena were witnessed in blind subjects and in those whose eyes were closed. He found also that vertigo could be excited in this way with a current too feeble to excite ocular movements.

These remarkable experiments have been used by different authors as confirmatory evidence of the three following propositions: 1, that the symptoms produced indicated an anelectronic and catelectronic state of the respective auditory nerves; 2, that the cerebellar structures were called into action by the current; 3, that parts of the cerebrum were affected by the current.

The experiments of Cyon afforded ground for the first proposition, since he found that, when the semicircular canals of the ear were divided, peculiar "forced movements" and a loss of co-ordination were produced. The symptoms noticed in auditory vertigo (Menière's disease) are strongly in accord with these experiments, since slight defects in hearing appear to produce in some instances alarming vertigo, vomiting, and unconsciousness.

The second proposition seems improbable, because the seat of the electrodes would appear to be too far removed from the cerebellum to directly affect it.

The third proposition is based upon the situation of the electrodes and the fact that the electric current may be supposed to pass in the most direct line through the cerebral substance. It is possible that the artificial current is sufficiently strong to arrest in its passage the cerebellar current which constantly flows into the cells of the caudate nucleus of the corpus striatum, and that the symptoms of vertigo and inco-ordination are to be thus explained.

From a standpoint of our present knowledge, the cerebellum must be considered as the "terra incognita" of the brain. The clinical evidence is discordant. The anatomical connections of the cerebellum with other parts of the nervous system are remarkable, and their minute structure is, as yet, imperfectly understood. The region overlapped by the cerebellum is interspersed with important collections of gray matter which act as nuclei of origin for important nerve-tracts; so that all experiments made upon the cerebellum itself or its peduncles are liable to cause injury to some of the neighboring parts, and thus to yield results which are puzzling and unreliable. Conjecture inevitably forms an important element in all of the theories advanced respecting the functions of the ganglion itself, or of certain of its parts. Nothnagel claims to have demonstrated that mechanical stimulation of the surface of the cerebellum will give rise to muscular movement without signs of pain being perceived. He found that these movements developed slowly, appearing first on the side operated upon and then ceasing, only to appear upon the opposite side. He states that he has demonstrated that the fifth, facial, and hypoglossal nerves, as well as nerves distributed to the trunk and extremities, can be thus called into action. The same observer concludes that destruction of the *commissural fibres* of the cerebellum alone produces inco-ordination of movement. Hitzig and Ferrier believe that injuries to the lateral lobe produce the same varieties of "forced movements" as are noticed after section of the middle peduncle. Flourens observed that injuries to the anterior or posterior parts of the median process caused animals to fall forward or backward respectively, and his views have been confirmed by others. Ferrier found that stimulation of the cerebellar cortex by the interrupted electric current produced in monkeys, cats, and dogs

movements of the eyeballs, with associated movements of the head, limbs, and pupils. Adamuck produced the same effects, however, by stimulating the corpora quadrigemina. Hitzig refutes the view that Ferrier's results were due to an escape of the current by claiming to have produced similar effects by mechanical irritation of the cortex. Eckhard has brought forward facts which tend to show that in certain parts of the cerebellum lesions tend to produce diabetes or simple hydruria, thus resembling the effects of irritation of the medulla in the region of the floor of the fourth ventricle.

In the face of this conflicting mass of experimental evidence, I mention now one of the most plausible and attractive theories respecting the relation of the cerebellum and cerebrum to muscular contraction, which has been advocated by Spencer and sustained by Hughlings-Jackson, Ross, and others. It is believed by these authors that all *continuous tonic muscular contraction* is governed by the cerebellum, and the *alternate or clonic muscular contractions* by the cerebrum, in so far as they are required to maintain a posture or produce a change in attitude. In all efforts to maintain an attitude (once assumed as the result of some cerebral impression received), the cerebellum holds the muscular apparatus in its proper state of tonicity; but when the attitude is to be changed, for any possible reason of which the cerebrum is conscious, the proper muscles are relaxed and others thrown into a state of contraction by means of the higher ganglion. The body is then entrusted to the influence of the cerebellum if the attitude is to be again

FIG. 4.—A Diagram designed to illustrate the Encephalo-Spinal Action. (Modified from Ross.) C, cerebral cell; C', cerebellar cell; S, spinal cell; 1, fibres connecting the cerebellum with the optic apparatus; 2, fibres connecting the same with the auditory apparatus; 3, fibres connecting the same with the tactile apparatus; A, afferent fibres of the cerebrum; A', fibres connecting the cerebellum with the cerebrum; E, efferent fibres of the cerebrum to the spinal cells; E', efferent fibres of the cerebellum to the spinal cells; 5, 6, motor fibres from the spinal cells to the motor plates of muscles (M); 4, afferent (sensory) fibres from the peripheral parts of the body to the cells of the spinal cord (3 has probably a communication with the spinal cells before reaching the cerebellum). Note that each of these three sets of nerve-cells possesses a group of afferent (sensory) as well as efferent (motor) fibres connected with them; also that each can thus exert an automatic action, when required to do so, or be governed at other times by the cells of the ganglia above.

maintained. Thus it is suggested that the cerebellum be considered as capable of automatic action, but still as a subordinate to the cerebrum, which possesses the power of overcoming it in one of two ways: First, by increasing the supply of nerve-force to certain sets of cells, then under the influence of the cerebellum, and thus altering their action upon muscles; or second, by inhibiting or totally arresting the cerebellar influx to the antagonistic sets of muscles. Both are designed, according to this view, to act either automatically or in unison, but the cerebellum is the servant of the cerebrum to do its bidding when required.

It will be at once perceived that this theory applies to the complex physiological acts of walking; the prolonged maintenance of any given posture; the transfer of the

centre of gravity; the passive state of groups of muscles; and many of the morbid phenomena observed in muscles, as the result of impairment of the higher nerve-centres. It will be impossible to discuss all of these conditions in this connection. Hughlings-Jackson and Ross have covered the more important points in their works. If we form our views of the physiological functions of the cerebellum purely from the standpoint of the anatomical connections which that ganglion is known to possess, we cannot but agree with Bechterew in some of the conclusions which he has lately advanced. This author believes that the cerebellum is intimately connected with three organs, which tend to exert an influence upon equilibrium, as follows: First, the *semicircular canals*, connected with the organ of hearing; second, the *organ of sight*, since the movements of the globe of the eye and possibly the sense of vision may be traced to a relation with the gray matter in the floor of the third ventricle and subsequently with the cerebellum; third, the *olivary gray matter*, which the author thinks is probably connected with the organs of tactile sensibility.

The views of this author have been in part anticipated and sustained by Spitzka, who, in an article published about two years ago, considered the cerebellum as the centre where "impressions of touch and position are associated with those of time and space," and hence the seat of coördination of the most delicate forms of movements; such as are necessary, for instance, to the proper adjustment of the drum-membrane of the ear for the correct appreciation of sounds, the appreciation of time and rhythm, and the finer acts of equilibrium. In filling this position, the latter author believes that the cerebellum is subordinate to the cerebrum, to which it acts as an "informing depot" for coördination, rather than as a distinct centre.

Progress of Medical Science.

RECOVERY AFTER A LARGE DOSE OF DIGITALIS.—Dr. Antonin Martin reports in *L'Union Médicale*, for September 18, 1883, the case of a man, forty years of age, who had taken through mistake an infusion containing six hundred grains of digitalis leaves. He was not seen until twenty-two hours after the accident, at which time he was vomiting incessantly, the skin was cold and dry, the extremities were cold, and he complained of pains in the legs; there was no headache, the pulse was slow, 25 to the minute, strong and regular. Two days after the digitalis had been taken, he began to suffer with intense cephalalgia, located in the left side of the frontal region, and at the same time there were troubles of vision. The patient saw bright specks dancing before his eyes, and even figures of all sorts of animals. Two days after this again he was seized with aphasia, which continued for four days and then ceased. After this the cephalalgia disappeared and the visual disturbances gradually subsided. The recovery, Dr. Martin thinks, was attributable to the poor quality of the digitalis rather than to any remarkable powers of resistance to the poison on the part of the patient.

TREATMENT OF CATARRHAL OTITIS IN INFANTS.—In catarrhal otitis of the new-born, poultices should be applied to the pavilion, and injections made into the auditory canal of a decoction of poppy heads as hot as can be borne. As soon as a discharge is established, a little borax is to be added to the injection. When the pain is severe, a pledget of cotton dipped in an oily solution of morphine may be placed in the ear. When the pain seems to be nearly gone the decoction of poppies may be replaced by a one per cent. solution of chloral, warmed, and injected slowly by means of a small syringe. Finally, when the pain has ceased entirely, an application of alum and glycerine (1 part to 20) is to be made after each injection.—*L'Union Médicale*, September 18, 1883.

ANTISEPTIC SUGAR DRESSINGS FOR WOUNDS.—Dr. Fischer reports in the *Centralblatt für Chirurgie* for August 25, 1883, that he and Professor Lücke have used this application in several instances with satisfactory results. They have used a mixture containing equal parts of sugar and naphthaline, and one of iodoform one part to sugar five parts. The mixture is rubbed into gauze, which is applied over the line of suture, or, where there is a loss of integument, the sugar is strewn directly upon the tissues. Sugar cushions were prepared and used in the same way as peat or sublimate sand cushions. The dressings may be left *in situ* for eight or ten days. The secretions are diffused equally throughout the mass of sugar, except when the layer is too thick it sometimes becomes lumpy. There was never any bad odor about the dressings, even when they had been on a long time. Granulation proceeded finely under the sugar; there was no bleeding, and cicatrization was quickly accomplished.

IRREDUCIBLE PHALANGEAL DISLOCATIONS.—In a patient under the care of Dr. Weinlechner there occurred a dislocation of the thumb from over-extension. Although the thumb could be replaced and the joint surfaces separated for some distance by traction, as soon as this was remitted the phalanx returned to its former place on the dorsum. Even after a resection of the head of the metacarpal bone, the luxation was still irreducible. No cause could be found for this, as neither the palmar portion of the capsule nor the tendon of the long flexor was interposed between the ends of the bones.—*Centralblatt für Chirurgie*, August 25, 1883.

In the following number of the same journal is the report of a case by Dr. Willemer of dislocation of the index finger. Although, as in the former case, it could be easily reduced, it could not be retained in its normal position. An incision was made, when the obstacle to reposition was seen in a small sesamoid bone in the capsule of the joint, which had slipped in between the ends of the bones. This was removed, and the finger was then easily retained in place.

TREATMENT OF RECTO-VAGINAL FISTULÆ.—In cases in which the fistula is situated not more than an inch above the anus, Dr. Monod incises the perineum up to the seat of injury, freshens the edges of the fistula, and then closes the wound by deep sutures passed from the vagina. In order to insure success, he recommends that, prior to the slitting up of the perineum, a stick of nitrate of silver be introduced into the fistula and passed carefully around its entire circumference. By this means the edges are whitened, and can be easily recognized during the operation.—*Centralblatt für Gynäkologie*, September 8, 1883.

URETHRAL CALCULI.—In a recently published monograph upon calculi in the male urethra, Dr. Maximilian Zeissl relates several hitherto unreported cases of this affection. Most frequently the calculi have a renal origin, but sometimes are formed in the urethra itself from particles of mucus which become lodged behind a stricture, in the bulbous portion of the urethra, in the fossa navicularis, or in some diverticulum. They may also be formed from some pieces left behind after an operation for stone in the bladder. The lumen of the urethra is narrowed and sometimes completely closed by the continued growth of a calculus. In other cases stones are formed about foreign bodies introduced from without. Frequently the stones are seen to be channelled out on one of their sides, so as to afford a passage for the urine. The diagnosis of urethral calculi may present great difficulties when they lie in a diverticulum, and also at times when they occupy the prostatic portion. When the urethra is large, it is sometimes possible to push an impacted stone back into the bladder, and then to extract it through a large eyed catheter. If this procedure fails, the calculus is to be removed by an instrument adapted to the purpose, or by direct incision through the wall of the urethra.—*Centralblatt für Chirurgie*, September 8, 1883.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

SECONDARY DEGENERATION OF THE SPINAL CORD—SOME NEW FACTS.

PROF. SCHULTZE, of Heidelberg, successor to Erb in the chair of Nervous Diseases, has recently published (*Arch. f. Psychiatrie*, xiv., 2.) an article upon the pathology of secondary degeneration in the spinal cord, which contains many new facts. His conclusions are based on a study of microscopic sections of the cord at different levels in five cases of compression myelitis. In each of these cases the compression was exerted on different parts of the cord, from the cauda equina to the cervical enlargement. In one of these cases the symptoms, persisting for seven years, were paralysis and anæsthesia in the regions supplied by both sciatic nerves, and the lesion was limited to them near their origin. In the other cases the lesion involved other nerves as well. All the cases were accompanied by ascending degeneration in the cord, limited to the posterior columns and to the direct cerebellar columns.

In regard to the degeneration in the posterior columns, Schultze finds that while the entire posterior columns, except a small zone to be mentioned below, are involved just above the lesion, the area of degeneration diminishes as it ascends, and is limited to the columns of Goll, *i.e.*, the posterior median columns, at the level of the cervical enlargement. In the case in which the sciatics alone were involved, the area of degeneration in the cervical region was limited to the posterior and inner portions of the columns of Goll. Where all the nerves below the eleventh dorsal segment were cut off from the brain, the entire column of Goll was involved. When the lesion was still higher, the columns of Burdach—*i.e.*, the posterior lateral columns, as well as the columns of Goll, were in a state of degeneration. He concludes that the extent of the area of degeneration is in exact proportion to the clinically ascertained disturbance of function, *i.e.*, the more sensory nerves cut off from communication with the brain the greater the area of degeneration in the cord. The tracts connecting the sciatic nerves with the brain lie in the inner and posterior part of the columns of Goll. The tracts connecting the lower extremities with the brain lie wholly in the columns of Goll, and are sufficient to make it up. Hence the columns of Goll in their entire extent are connected functionally with the sensitive nerves of the legs, and not with those of the arms as well. The longest bundles of

centripetal nerves lie in the columns of Goll, just as the longest bundles of centrifugal nerves lie in the pyramidal columns. As nerve after nerve enters the cord as we ascend from below upward, its fibres arrange themselves in succession, laterally and posteriorly, in the posterior columns, taken as a whole, the sciatic nerve-fibres lying farthest back and most nearly to the median fissure, those of the crural nerves next to these and bounding them antero-laterally, those of the dorsal nerves next, and lastly the fibres from the cervical nerves filling up the columns of Burdach.

Since the area of degeneration after a lesion at any point becomes smaller as it ascends, it follows that a part of the fibres which were degenerated near the lesion either stop short, or cease to degenerate as they ascend. The latter is improbable, since it is in the very longest fibres, *viz.*, the sciatics, that degeneration is always found. Hence it is probable that a part of the fibres which enter the cord from the nerve-roots and start upward in the columns of Goll, end without reaching the medulla. Schultze therefore distinguishes long and short nerve-fibres in the posterior columns. He thinks that at first, *i.e.*, opposite any given nerve-root, these are mingled, but higher up the long fibres alone remain, and are collected together in the posterior and inner part of the posterior columns, in the order previously mentioned. A sharp line cannot be drawn at present, however, between the median long and the lateral short tracts at every height.

In the area of degeneration in the posterior columns just *above* the lesion, there is always to be found a small half-moon-shaped zone lying next to the posterior gray roots and free from evidence of change. Just *below* the lesion, however, a similarly situated area is found degenerated, though no other part of the posterior column is here affected. Schultze considers that this is proof of the existence of fibres from the posterior nerve-roots which bend downward after entering the posterior columns. Such fibres are only 2 to 3 ctm. in length, as determined by the extent of degeneration. This confirms the statement of the anatomist Schwalbe. There is, therefore, a small amount of descending degeneration to be found in the posterior columns, as well as a large amount of ascending degeneration after a transverse lesion.

In regard to the ascending degeneration in the direct cerebellar columns, Schultze finds that it occurs only when the lesion is located at a point higher than the last dorsal segment of the cord. The fibres to these columns are known to have their origin in the large gray cells of the postero-internal gray matter of the dorsal region—the columns of Clarke. As long as connection between these cells and the brain remains, the cerebellar tracts do not degenerate. Lesions above the last dorsal segment will break this connection and produce the degeneration. Schultze maintains that these direct cerebellar columns extend further forward than in Flechsig's diagrams, and states that when they are degenerated the zone of degeneration reaches the anterior nerve-roots, without, however, involving them.

In regard to descending degeneration, Schultze also makes an addition to our knowledge. Such degeneration has been supposed to be limited to the direct columns of Türeck, *i.e.*, the anterior median columns; and to the

crossed pyramidal tracts in the lateral columns. Schultze shows that in all his cases there was also a decided degeneration in the anterior and in the lateral columns, extending from 8 to 10 ctm. below the lesion. He considers this evidence of the existence in these columns of short centrifugal fibres connecting adjacent segments of the cord.

The lateral fibres lying just adjacent to the gray matter escaped degeneration in all cases. Hence they will neither degenerate upward nor downward. It has been supposed that these fibres convey impulses in both directions, and thus connect reflex arcs. Schultze prefers to consider them as in connection with gray ganglion-cells at both ends, and thus capable of being nourished from the cell at either end.

As to the nature of the process of secondary degeneration, Schultze declares himself in favor of the theory that the increase of connective tissue is a consequence of the destruction of nerve-fibres, and suggests that the debris of degenerated fibres acts as an irritant and produces the connective-tissue inflammation.

The difference between degeneration in the posterior columns secondary to compression, and the degeneration present in locomotor ataxia, is that in the former the short fibres escape except at the level of the lesion, while in the latter both short and long fibres are involved in the entire cord. Schultze finds a support for his statement that the columns of Goll are made up of fibres from the lower extremities, in the fact that in cases of ataxia where the legs are most implicated, the lesion is most intense in these columns in the cervical region; but where the arms also are involved, the lesion extends beyond them to the columns of Burdach.

Schultze urges a microscopic examination of diseased cords, as these distinctions are impossible from the macroscopic appearance.

AN UNUSUAL ADDRESS.

THE lambent flame of the average London introductory address burst up into something like fireworks a short time ago, beneath the breath of Dr. T. Clifford Allbutt, lecturer in the Leeds School of Medicine. It is plain from reading his address that Dr. Allbutt is not an ordinary orator, nor a commonplace thinker, whatever else we may call him; for in the space of an hour he trod with a perceptible pressure upon each particular toe, so to speak, of the British foot medical.

First of all, the speaker declared that the doctor's profession is not inherently a noble one. We beg our readers to listen to the heresy:

"As to the nobility of our calling, a man may sell fish to the glory of God—that, remember, is as it may please you to make it."

"Essentially speaking, to patch up a man's clay carries to my mind no sense of inherent nobleness as a calling. Skill, knowledge, acuteness, all these it must have, nobility, none necessarily. . . . Like him who made two blades of grass grow where one grew before, the doctor's useful business is to conserve or develop forces for higher ends than his own. If we be driven to such an issue, it is better we should be a free and great-hearted nation

than a healthy one!"—not mentioning the fact that unless you are healthy you are not very likely to be great-hearted. Dr. Allbutt dwells much upon the "ignoble ease" of a too sanitary existence, and recommends his hearers "to die young gloriously" rather than "live ignobly for a century."

The doctor, according to our English orator, is a kind of homoculturist, who prunes, purges, and fertilizes, that fruit may result. His services are personal and private, are rendered to the individual, not to the State. Therefore the doctor does not deserve and should not clamor for State rewards or distinctions (alas for the medical knights and baronets!); his reward is in his work.

But Dr. Allbutt is just enough to say that, although the doctor's life is not essentially a noble one, yet practically it generally is such.

"Do I say, then, that your lives shall be mean lives? God forbid."

"The general practitioner of medicine, as I often witness, even to my shame, devotes his profession, and indeed his life, to the good of others, after a fashion which ennobles any work. Herein, gentlemen, is our true patent of nobility, loftier far than any coronet. The doctor who does, however honestly, only the work that he is paid for is rare in the ranks of general practice; and his life, I repeat, is a useful, but not a noble one. General practitioners obey a far larger and more lovely idea than that.

"Our brethren walk fearlessly, unconscious of heroism, beside the pestilence, snatching men from its breath, and bearing away the stricken to safety. When the typhus epidemic fell upon us in 1865, and our fever hospital was a pest-house, men from general practice stood by me, holding their own lives cheap, at the call of duty and humanity. Mr. Burroughes died at his post; Mr. Swann died at his post; Mr. Libby, happily now living, was smitten heavily, and barely rose again from his bed. Yet I had no lack of volunteers."

In speaking at first of the personal character and secondary value of the doctor's service, slight mention is made of his work in preventive medicine. One must but feel that there is some injustice in sentiment and fallacy in argument here, as well as previously, for, after all, personal service and individual happiness form the ultimate aim of every kind of social work and political endeavor. State services, if we examine them closely, are really only valuable because they increase individual happiness, are in the end personal. Is it better or nobler to pass a tax-law than to prevent an epidemic? Dr. Allbutt makes amends for his first generalizings by the following concreteness:

"Less brilliant, but, in its steadfast unselfishness, perhaps incomparable, is the voluntary sanitary work done by general practitioners before the establishment of sanitary districts. Of these services the careless public is yet scarcely aware. Did the members of any other profession ever seek odium, and even rancorous enmity, by persistent endeavors to cut down their own incomes in the interests of their clients? To speak plainly: enteric fever, for instance, was worth perhaps a steady hundred a year to many a town or country practice—not counting the luck of epidemics. Now, hundreds of doctors—you know many of them yourselves—in human pity,

have striven to suppress this and other such maladies; spoiling their own incomes, and earning, not the thanks, but even the curses of the public; offending not the poor, but the rich—the landlords, the thriving farmers, the Poor-law guardians—the class upon whom the rest of their shrunken practice must depend.”

Perhaps we cannot on the whole complain of Dr. Allbutt's picture of the medical life. It is that doctors are of ordinary human clay, but that most of them find and use the rich opportunities for noble and self-sacrificing acts that a medical career furnishes. He should, Dr. Allbutt thinks, get his pleasure and reward in his work alone; and this is well, but we would add: Why not let him aspire to something further and higher if he wishes? The standing of the profession will be measured by its claims. If it is content to be a drudging, clystering business, it will remain such. Despite Dr. Allbutt, we say, let not the doctor think that a round of noble toil ignobly rewarded is the all that his profession offers. If there be high rewards in science, art, social regard, or governmental recognition let him get them if he can.

THE PRONUNCIATION OF MEDICAL WORDS.

A CORRESPONDENT from Mendon, Mich., writes us as follows:

“I have long noticed that among physicians there is a want of unanimity in the pronunciation of certain medical words, such as the termination ‘itis’ in bronchitis, etc., rôle, quinine, and perineum. Will you please give us the accepted pronunciation of these words and thus oblige.”

It is very unfortunate that there is no absolute standard for the pronunciation of many medical terms. Those that are derived from the Latin and Greek are pronounced by most teachers and lecturers chiefly according to the Continental or Roman methods. Many words, however, would not sound familiar if so pronounced, and consequently a sort of mongrel orthoëpy prevails. But even apart from this mixed and unjustifiable method, which applies chiefly to anatomical nomenclature, there are many commonly used words which are as frequently mispronounced.

We append here a few of them:

Abdomen has its accent on the penult, not the antepenult.

Excretory is accented on the antepenult.

Fibrile has a long *e* and a short *i*, the latter pronounced like *i* in hit, according to most authorities.

Hy- or *Hyd-a-tid* has the accent and division of syllables as indicated.

Maxillary has the accent on the antepenult.

Midwifery is accented as shown.

Phthisis, bronchitis, and all words ending in the inflammatory “itis,” are pronounced with a long *i* like that in mite, according to nearly all lexicographical authorities. The customary pronunciation of these syllables, however, in all parts of the United States (except to some extent in New England) is to give the *i* the sound of long *e*, which it had in its original Greek derivative. A custom so long and universally sanctioned, upheld by etymology, gives authority to this pronuncia-

tion and we believe it to be more justifiable and correct, as it certainly is more euphonious, than the lexicographical one.

Quinine, according to all dictionary authorities, has the first syllable pronounced like “kwi.” The word is variously divided and accented, there being no settled authority either as to this or the length of the vowels. No English or American lexicographer admits the very common pronunciation “kee-neen.” Yet we believe that this last is the more correct. Quinine was originally, and is now as it stands, a French word, and naturally should have the French pronunciation. Custom has given it this, although the dictionaries would take it away. An English equivalent, such as “quinia” might very properly be used and pronounced as an English word.

Secundine has its accent on the antepenult.

Trephine is accented on the last syllable.

Vaginal, according to most authorities, is accented on the antepenult, although the noun vagina is accented on the penult.

Emesis, not *Emé'sis*.

The list of words given in most dictionaries, whose pronunciation differs, according to different authorities, includes nearly fifty medical terms.

It follows that a correct medical pronunciation is not an easy thing to obtain, though a vast improvement might be made on the present practice.

A PRACTITIONER WHO IS NOT BUSY.

WE print below a letter received from a correspondent living in a large city. The author is apparently very much in earnest, and his appeal for advice will doubtless be found interesting to many. He writes:

“Dear Sir: I have a question to propose not very easy to answer. I am a man of two years' practice who has met with a fair measure of success. I have realized each year the income that Dr. Willard Parker, in his article on “Success in the Medical Profession,” names as the limit. I have a comfortable office, an examining room, and another apartment. I have besides my fees about two hundred a year. I am just able to make both ends meet and to have a little pleasure; yet without having any real hardships I am discontented. Now, the great cause of this discontent is idle time. The major portion of the day I have nothing to do. I am not connected with any school, hospital, or dispensary, and don't know how to get at them. I am sick of reading. I must have an object in my pursuits, and it must not be too distant, and I do not think I am alone in this. Now, studying up diseases which one does not see and delving into abstrusities that one can never ventilate is rather tasteless at the end of two years. But what am I to do with my time? Set me some task, tell me what I ought to do, lay out some useful line of study, anything with an end in view which a man with some resources, a fair mind, and an illimitable amount of energy can do. There must be a positive object within reach that is essential to interest in the work. Few of us like work simply for the work's sake. Do not think that I have no interest in my profession. I love it above all other work, but I love it in its practicable rather than in its sci-

entific aspect. There must be something to be accomplished, a test of the work—that is what I desire. Now can you solve the problem? I am but one of many, but am among the worst, as being the most restless. Very respectfully, A Master of Arts and Doctor of Medicine, an idle man with a desire for work."

It is somewhat rare to find a person of illimitable energy who can find nothing to expend it on. Perhaps our correspondent is mistaken about his being so industrious, and that what he thinks is energy is only restlessness and incapacity for systematic application. He has evidently, in reading medicine, been at it in a haphazard way. He should try studying some special line. Does he know German and French? If not he will be sorry later to find himself handicapped in his future struggles, when a busier man. To a person with "illimitable energy" there is no trouble in finding some dispensary-work, even if in the humble capacity of assistant or substitute. There are numerous physicians in the city who would be glad to have the leisure our correspondent deploras for such literary and scientific work as would supplement their practical experience. Our energetic correspondent should find out these and offer his services. Is there no practical work in the societies, clinics, hospitals, or dispensaries which pleases him? If so, let him attend these places and stick on till he finds some one whom he can tender his leisure to, or who will find some work for him.

We fear that our correspondent in reality lacks energy and perseverance.

THE RIGHT TO KILL MONSTROSITIES.

SOME correspondence has appeared in the columns of the *Boston Medical and Surgical Journal*, as to what physicians should do with living monstrosities, which they have just delivered. One correspondent writes that an old physician of high character and standing, had always been in the habit of killing them immediately after they were brought into the world. The writer himself had been content with simply neglecting them, hoping that life would cease if the ordinary precautions were not taken.

The question of what medical conduct should be in these circumstances is one that has often been raised. It appears, on the face of it, more humane both to child and parent to destroy a life which is at once revolting and painful. And it has even been claimed that the physician exhibits a moral weakness and timidity in refraining for personal reasons from "stilling the 'wrongly' spun life."

The same line of argument has been raised also as to the application of euthanasia in cases of painful and fatal disease. An ex-Judge of this city has openly and eloquently argued that it is right and justifiable to end the intolerable agonies of the moribund by medicinal means. In Paris, a fund has even been left for the creation of an institution where euthanasia may be practised.

Despite the strong case which apparently exists for the views thus cited, there is, so far as the medical profession is concerned, no justification in adopting them. Society requires for its own safety that human life in every form should be considered sacred. The physician in his in-

dividual capacity has no right to say that any spark of vitality, however feeble or miserable, shall be extinguished. If, in obeying this principle, he causes some increase of individual suffering, the general results of his conduct will be for the true interests of society. He should not destroy, either by active means or passive non-interference the life of even the most misshapen monsters.

POISONING BY STRYCHNINE—THE TRIAL OF MRS. COATS, OF BULWER, QUEBEC.¹

A RECENT trial for murder in the city of Sherbrooke, Province of Quebec, has caused intense excitement throughout the eastern townships of that Province. The facts, briefly stated, are as follows: On August 26th, ult., a respectable young merchant, of Bulwer, Quebec, suddenly died, with all the symptoms of poisoning by strychnine. Suspicious circumstances pointed to the wife of the deceased as the person who administered the poison. An inquest was held and a post-mortem examination was ordered, the results of which confirmed the suspicions that Coats had died from strychnia given by his wife. The latter was accordingly indicted for murder, and the trial has lately concluded with the acquittal of the accused woman. Such, in brief, are the facts. A more particular statement of certain features of the affair, brought out by the trial, will be of interest to physicians.

Mr. Coats had been in his usual health till within an hour of his death, when, complaining of a little pain from indigestion, his wife prepared for him, in molasses, and gave him what she called a dose of rhubarb powder. Tetanic convulsions in a few minutes supervened, from which Coats soon died, in the presence of two neighbors who were hastily summoned. The limbs were rigid and the jaws were set; the mind remaining clear to the last. The only explanation that the accused could give of this singularly sudden death was that the deceased had a short time previously eaten choke-cherries and drank freely of milk. The autopsy, which was conducted with sufficient care, revealed no choke-cherries and no milk-curd, and nothing apparently which could cause death. The contents of the stomach, however, on being submitted to an expert, were shown to contain a considerable quantity of strychnine, as proved by the bichromate test and by the frog test. Several frogs died in a few minutes from tetanic convulsions by being slightly wounded in their legs and then put into a filtered solution of the contents of the stomach of the deceased.

It was shown by the prosecution that there was a motive for the murder, and that the means—with too little adroitness—had been provided. A guilty correspondence with a paramour had been for some time going on, the prisoner writing to the latter under a fictitious name. It was also proved that the prisoner had been unfaithful to her marriage vows. On August 23d, just three days before the murder (which, with all the evidence before us, we cannot but regard as such), Mrs. Coats had taken from the post-office a letter from a neighboring apothecary, addressed to her care, and containing fifty cents worth of strychnia! This fact was not

¹ Report of trial of Mrs. S. E. Coats, for poisoning her husband by strychnine. Examiner's Office, Sherbrooke, P. Q. J.

denied by the defence, nor was any explanation attempted of the circumstance, or of what use was to be made of it, or of what disposal was finally made of it.

Mrs. Coats (who is said to have been young and good looking) was acquitted, although the judge strongly charged the jury to convict. Three or four circumstances contributed to unsettle and confuse the jury, and these it may be well to state.

It was alleged that the medical men who conducted the autopsy had been negligent in leaving the stomach of the deceased man exposed in an open jar for half an hour in a room to which any one might have had access while they were giving their testimony before the coroner's jury. During that time, said the defence, somebody might have tampered with the stomach, putting in a little strychnine! Foolish as is this plea, it doubtless had some weight with the jury. It is true that physicians conducting an autopsy where such important issues are at stake cannot be too careful to make such strictures and censures impossible. If the stomach is to be examined on the spot let it be done at once and before competent witnesses. If the contents of the stomach are to be removed let it be done immediately before witnesses, and let the jar containing the stomach or its contents be hermetically sealed till the proper time for examination. This is a medico-legal point of great importance, and it is surprising through what a little loophole lawyers for the defence will sometimes contrive to squeeze their client!

The evidence of one of the medical gentlemen summoned by the defence was of a somewhat surprising character. He regarded experiments performed on frogs with a view to determining the physiological action of toxic agents as unreliable. In the particular instance the tetanic convulsions from which the frogs died as a result of the experiments made to determine the nature of the contents of the stomach of the deceased man might have been caused by the incision in the legs of these animals; such wound having been made to facilitate absorption of the poison! Other frogs with similar wounds in their hind legs and placed in plain water did not have convulsions or apparently suffer. As if this specious pretence might not have sufficient weight with an ignorant jury, this same village expert gave as his opinion that septic products of decomposition, generated in the stomach of the dead man during the three days that elapsed between the decease and the examination, caused the convulsions in the frogs, and that Coats died of idiopathic tetanus! It is hardly necessary in a medical journal to comment on such a silly assumption, which was set aside by His Honor the judge as not worthy of serious consideration. There are, however, one or two points in this connection worthy of note. "Truth never can be confirmed enough," says Shakespeare. The analytical chemist should have carried his investigations farther. Having obtained a filtered watery extract of the stomach of the deceased, he should have tested it *by the hypodermic method* on frogs, and on animals higher in the scale; kittens, rabbits, fowls, dogs, etc. Then if he had produced speedy tetanoid convulsions, there would have been no reasonable basis for doubt. If the gentleman who gave such remarkable testimony for the defence had ever performed on animals experiments with the subcu-

taneous injections of septic fluids, he would not have risked his reputation by attributing the results which Dr. Vallie, on the occasion above referred to, obtained with his frogs to septic poisoning.

It is, moreover, always well when performing an autopsy that is likely to be of great medico-legal importance to remove by a catheter some of the urine of the deceased person for chemical examination. If the death had been caused by strychnia, enough would surely have been absorbed to affect the urine in which its presence might have been detected. If the color test be somewhat unreliable, surely as confirming other tests it cannot but have considerable weight; nor has it been shown that any substance except curare produces with bichromate of potash and sulphuric acid precisely the same colors as strychnia. But curare as a medicine or poison is almost unknown in this country.

THE WATERCOURSES IN NEW YORK CITY.

In view of the opinion expressed by many that New York city does not have the conditions (except in a few localities) for engendering malarial diseases, it is interesting to study some of the maps of the city which show the track of old watercourses. It is estimated that the volume of water drainage from the eighteen miles of sluice built above Fifty-ninth Street on the west side exceeds that of the sewage which empties just below it.

In 1871 there were 5,000 acres of undrained land in New York County. In 1873 there were still 2,500 acres of water-saturated land.

Of the watercourses south of Fifty-ninth Street there still remain traces of one, perhaps the largest, which is or was known as Minetta Water. This stream arose from two sources, nearly as high as Twenty-first Street, and drained the back-bone of the island for some distance, finally emptying into the North River.

In the earlier part of the present century, according to a writer in *The Times*, the Minetta, near Eighth Street, was a stream twelve feet wide. There is no reason to believe that its bounds became more circumscribed as it crossed Washington Square on its way to the fresh water pond and the North River. This width represented merely the actual width of the stream, which is said to have been a lovely brook, flowing between low banks. The ground, saturated with its waters, must have extended for some distance on either side, and this marshy territory was greatly increased when the hills were scraped down into the channel, streets graded, and the course of the water dammed. Fed by living springs, Minetta is to-day still an actual stream of water. The diminution in its volume is not due to the cessation of the springs which fed it one hundred years ago and feed it to-day, but to the diversion of at least a portion of the drainage, which formerly found its way into the stream, into the sewerage system of the city.

In 1859, a physician who had practised in New York for many years stated that he could trace the course of the stream by his practice in intermittent fevers.

Later experience has, we believe, shown that malarial fevers were frequent on the course of old streams. As the earth has become saturated with animal matter the types of fevers have changed.

News of the Week.

THE LATE DR. BEVERLEY LIVINGSTON.—At a stated meeting of the New York Pathological Society, held October 24, 1883, the following memorial tribute to the memory of the late Dr. Beverley Livingston was unanimously adopted: The decease of our late colleague, Dr. Beverley Livingston, brings to the Pathological Society an uncommon sorrow. When in the fulness of years one of our number is called from our midst, the knowledge that separation must come at last and the pleasurable recollection of completed labor reconcile us to our loss. But when we are deprived of the counsel of one who gave such promise of useful and invaluable aid, before whom there seemed to be a long and honorable career, and an almost achieved reputation, our sorrow is deep indeed. Dr. Beverley Livingston was distinguished by an earnest zeal, indefatigable industry, by love and devotion to his profession. While he gathered, in the pursuit of practice, some of the fruits which the latter yields, he gave an ample return by aiding, as an active co-worker with us, the advancement of science. Though his career was incomplete the lesson of his life is none the less perfect. To have won the respect and esteem of his colleagues, the admiration of his friends, to have been honored in the full discharge of his duties as a man and physician, is the reward which the memory of our late associate proudly and justly claims. The New York Pathological Society presents this tribute to the worthy family of the deceased, in the hope that in it they may find a better consolation than in words of sympathy.

H. N. HEINEMAN,

F. FERGUSON,

E. L. PARTRIDGE,

Committee.

THE INTERNATIONAL SANITARY CONFERENCE.—According to the Roman papers all the European powers have agreed to the proposition of Italy to send delegates to an international sanitary congress in Rome, in order to draw up an international sanitary code. The conference will meet during the present month of November.

THE SUCCESSOR OF THE LATE PROFESSOR LASÈGUE, M. Jaccoud, has been transferred, at his own request, from the chair of Internal Pathology to that of Clinical Medicine, left vacant by the death of Professor Lasègue.

THE ATTEMPTED MURDER OF DR. ROCHARD, a prominent physician of Paris, has excited much attention. The doctor, while walking along the street, was shot in the chest by a man who turns out to be a remarkable and interesting (except to M. Rochard) case of "Délire des Persécutions."

DR. TOMSA, of Kieu, has been appointed Professor of Physiology at Prague.

SOME IGNORANT CRITICISM.—*The Lancet* ventures to be facetious in an elephantine way over the "American Hay-Fever Association." This it considers an evidence of too great "differentiation of medical function," and suggests the formation of a "Bright's Disease Association," etc., etc. We would inform our insulated and

phlebotomistic contemporary that the association thus scornfully criticised is not a medical or scientific body, but is made up of sufferers from hay fever, who meet annually, in order, we are informed, to compare therapeutics.

THE GERMAN PHARMACOPŒIA.—The German Apothecaries' Society held its annual meeting at Wiesbaden recently, and appointed a commission to revise the *Pharmacopœia Germanica Editio II.*

A DRUGGIST SENTENCED.—A French wholesale druggist, who was accused of fraudulently substituting sulphate of cinchonidine for sulphate of quinine, which he supplied to the hospitals of Paris last autumn, has been sentenced to a year's imprisonment, to pay a fine of fifty francs, and to defray the expense of an advertisement of the judgment in a dozen French journals.

EXTIRPATION OF THE LUNG.—Dr. Domenico Biond has removed one entire lung fifty-seven different times in animals (sheep, dogs, cats, etc.), of which number thirty survived. In five instances, in which only portions of one or both lungs were extirpated, the animals all recovered. The failure, in the thirty cases of death, the experimenter attributed in great part to the neglect of proper antiseptic precautions.—*L'Union Médicale*, September 2, 1883.

THE PRICE OF QUININE.—According to the semi-annual report in *New Remedies*, quinine has within the past six months reached the lowest mark it has had for a long time. The chief cause of the depression was the competition between the European (Continental) and American manufacturers to monopolize the market in the United States, which was thereby overloaded. To realize on stock, sales had to be effected even at a loss and under compulsion, notably at one time the large amount of fifty-six thousand ounces, which were sold at auction in New York, London, and on the Continent at 195 marks per kilo. During June there suddenly appeared signs of a turning, the price advancing within a short time to 220, 240, and 250 marks. The simultaneous turn of the market permits the conclusion that there is an understanding among the manufacturers for the purpose of reducing exports to the United States, to refuse selling to speculators, to enforce higher rates for the article. Increased amounts of the cinchona bark are coming from India and Java.

A CREMATORY FOR THE VICTIMS OF YELLOW FEVER.—A crematory has been ordered built at Jurujaba, Brazil, in which the bodies of all patients dying from yellow fever at the marine hospital of St. Isabel will be cremated. This step is the result of the experiments of Dr. Friere, who has proved the existence of yellow fever germs in earth over the grave of a yellow fever patient who had been buried a year.

A PHYSICIAN TO BE EXPELLED.—At the semi-annual meeting of the New Haven County Medical Association, October 25th, the case of Dr. E. L. R. Thompson, a physician of large practice, who was recently indicted for illegal practice, was brought up. A motion that he be expelled was unanimously carried, subject to the consent of the State Medical Association.

QUARANTINING AGAINST LEPERS.—The quarantine officer of San Francisco is quarantining every vessel arriving in port having a leper on board. The vessel is released only upon the captain's giving a bond undertaking to return such leper.

THE PROPRIETARY RIGHT IN LECTURES.—A case of much interest was decided last week in the Court of Common Pleas of Philadelphia. The case was on a motion to dissolve the injunction recently granted to restrain Dr. Samuel M. Miller from publishing "An Epitome of Medicine, Surgery, and Obstetrics," in three parts, alleged to have been written by Dr. Alfred Stillé, Dr. Hayes Agnew, and Dr. R. A. F. Penrose, of the University of Pennsylvania. The complainants declared that the book was, in substance, a summary of their lectures before the medical classes at the University. Dr. Miller, they asserted, had contributed "nothing save the work of summarization and the errors to be found in the book." They never authorized the publication, and alleged that it deceived the public and tended to their financial and professional injury. Dr. Miller was formerly a student at the University. It was argued on his behalf that the matter, having been delivered at the lectures, became common property. It was urged that the students had never been notified that any right of property had been reserved, but, on the contrary, were directed to take copious notes, and the complainants had, in fact, corrected some of the proofs of their lectures that had been published in periodicals. Counsel for the complainants replied that a man has an absolute right of property in the production of his brain. Dr. Miller, it was held, had no right in law or equity to publish a book purporting to have been written by them, and to enjoy all the profits of the pretence, to the prejudice of the gentlemen whose names were used. The Court concurred in this view, and declined to dissolve the injunction.

The case involved a point somewhat similar to that raised in a suit in this city, a few years ago. A similar decision was made, viz.: that the lecturer had a proprietary right, so far as publishing goes, to his lectures.

WORK IN THE SECTIONS OF THE SOCIETY OF GERMAN NATURALISTS AND PHYSICIANS.—At the meeting of this Society, of which some account has already been given, considerable sectional work was done.

In the *Section for Pathological Anatomy*, Professor Bollinger reported the results of his experiments in the inoculation of tuberculosis. He found that milk from tuberculous cows, if injected into guinea-pigs, invariably caused tuberculosis. Bollinger declared himself unconditionally in favor of Koch's views of the specific origin of phthisis. Bollinger was warmly opposed by Recklinghausen, who took the occasion, when Friedlander exhibited specimens of the micrococci of pneumonia, to show the dangers of accepting too easily beliefs in the pathogenic powers of micro-organisms. He instanced the numerous forms of bacilli and bacteria which can be found in the dead body after various diseases. He did not think that Bollinger's experiments were conclusive. Professor Weigert, of Leipzig, stated that various inoculated substances will cause a pseudo-tubercle, but that only the tubercular virus itself will cause true tuberculosis.

In the *Section on Surgery*, Professor Küster described

his new method of controlling hemorrhage by the use of antiseptic iodoform tampons. It was especially to be used in wounds of very deep arteries not easily tied, such as the vertebræ. Englisch read a paper upon peri-urethritis tuberculosa, and Maas a paper on the treatment of goitre, giving the technique of his method of operating.

The *Section on Pædiatry* was occupied chiefly with discussions and papers on the subject of tuberculosis among children.

THE SEMI-ANNUAL MEETING OF THE AMERICAN ASSOCIATION FOR THE CURE OF INEBRIATES was held last week at the Fort Hamilton Home. Delegates were present from the New England States, New Jersey, Ohio, and Pennsylvania. The opening address was delivered by Dr. Joseph Parrish, of Burlington, N. J., the president of the association. Papers were read on "The Best Mode of Presenting the Subject of Alcoholic Inebriety to the Public Attention," by Dr. T. L. Wright, of Bellefonte, O.; "The Progress of Psychology," by Dr. Bradner, of Philadelphia, and "Inebriety Increased by Legal Punishment," by Dr. T. D. Crothers, of Hartford, Conn.

YELLOW FEVER IN MEXICO.—Reports from Mexico indicate that yellow fever has prevailed much more extensively in that country than is generally known in the United States. Acting-Assistant-Surgeon Main, in a letter to Surgeon-General Hamilton, dated October 16th, says that "but few Mexican papers reach the frontier, very few people read them, and fewer still reach or are read or understood in the United States." He reports that the disease continues to be quite fatal in the following named towns: Tabasco, Campeche, Progreso, Culiacan, Mazatlan, La Paz, Presidio, Concordia, Coraco, Qualian, Mazanillo, Mazatlan, and towns south and west of the latter places. There were 521 deaths at Mazatlan up to the 8th of October, and 381 deaths out of 3,000 cases in the State of Jalisco in ninety-two days. He says that Matamoras, Tampico, and Luxham are free from the fever, and that these places have modified their quarantine restrictions, requiring only eight days against Vera Cruz, but continue the twenty days' quarantine against Havana. He accounts for the latter cities' escape from yellow fever to be entirely due to their rigid quarantine and careful sanitary regulations. Reports from Havana up to the 20th of October, received by the Marine Hospital Service from Sanitary Inspector Burgess, show a slight decrease of yellow fever at that port, eighteen deaths having occurred during the week. Nine vessels bound for United States ports were inspected, four of which required disinfection. One, the bark *Neuvo Lautaro*, bound for New Orleans, had two cases of yellow fever on board during her stay of forty-five days at Havana, both of which recovered and sailed with their ship. Reports from Vera Cruz, through Sanitary Inspector Mainegra, indicate that the disease is rapidly disappearing from that section. He inspected and fumigated three vessels bound to United States ports during the week ending October 10th, and all sailed in good condition. Sanitary Inspector Chesley, at Benson, Arizona, and Sanitary Inspector Price, at Yuma, Arizona, report no further appearance of yellow fever northward, and they have both been relieved from duty and the quarantine at those places raised.

Reports of Societies.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

Stated Meeting, October 5, 1883.

ROBERT F. WEIR, M.D., PRESIDENT, IN THE CHAIR.
DR. A. A. SMITH read the report of a case in which death occurred a week after giving chloroform and apparently as the result of the anæsthetic.

DR. W. T. BULL presented a specimen illustrating
SARCOMA OF THE TERMINAL PHALANX OF THE SECOND TOE.

The patient had suffered from pain in the toe for some time. It was finally amputated by Dr. Bull. The following is the pathological report upon it by Dr. Ferguson :

Amputation of the second toe of the left foot at the phalangio-metatarsal joint ; in a male aged thirty-eight. The toe is surrounded by normal skin and the nail is normal in position and structure. The extremity of the toe is club-shaped, with a circumference of two and one-half inches, while the circumferential measure of the toe at the middle of the second phalanx is only one and three-fourths inch. A section through the toe longitudinally in the median line reveals a tumor occupying the site of the third phalanx, spheroidal in shape, and half an inch in diameter. The joint between the second and third phalangeal bones is normal. There remains at the base of the third phalanx a thin plate of bone covered by normal cartilage. To the dorsal aspect of this plate is attached the extensor tendon in its normal location. On the palmar aspect of the tumor there is a very thin, bony plate to which is attached the tendon of the flexor of the toe. Between the tumor and the nail there is a thin layer of normal tissue about a line in thickness. On the palmar aspect of the toe the skin and subcutaneous tissue are normal, except at the periphery of the tumor, where the subcutaneous tissue is more vascular, the vessels being surrounded by areas of small round cells. Generally the tumor is sharply circumscribed, and by the uniform pressure exerted on the tissues at the periphery of the tumor it seems in places limited by a fibrous capsule. In other places, however, it is not so sharply defined, and areas of considerable size are seen composed of cells not to be differentiated from the tumor structure ; these areas are separated from the tumor by broad bands of fibrous tissue, which exist normally in this location. The tumor is composed of small round cells and a few spindle cells, separated by a very small amount of intercellular substance. There are broad bands of fibrillated tissue, containing spindle cells, radiating from its centre to its periphery. In places there are small areas of fibrin with a few round and spindle cells, possibly the seats of old hemorrhages ; there is no recent hemorrhage. There are fragments of bone throughout the tumor. The vascular channels are abundant, quite large, and everywhere limited by the structure of the tumor, the vessels having no distinct walls of their own. There are no giant cells. Diagnosis, small round-celled sarcoma.

In the discussion THE PRESIDENT said that eighteen months ago he presented at another society two instances of tumors occurring on the terminal phalanx of the toe. One of these was a sarcoma the size of a pea, growing beneath the nail of the second toe and causing great pain. Amputation of the toe was resorted to. The second was an epithelioma which commenced under the nail of the great toe and developed to the size of a quarter of a dollar. Amputation was resorted to. These affections are very rare.

DR. C. S. WARD related a case of

PRURITUS VULVÆ DUE TO ULCER OF THE RECTUM.

About six weeks ago a lady came in from Newport for medical advice. She stated that for a long time she

had suffered from the most intense pruritus of the vulva. This was a source of so much distress at night that she had walked the house for hours. On examining the vulva no evidence of irritation was discovered. She was then anæsthetized and the rectum examined. Just above the sphincter was seen an ulcer about the size of a quarter of a dollar. Nitric acid was thoroughly applied to the spot and she very quickly recovered. The patient had had some pain after defecation, but nothing very noticeable.

DR. JAMES B. HUNTER related a case illustrating the
VALUE OF LEITER'S COILS IN THE TREATMENT OF PERITONITIS.

A young married lady, in perfect health, while bathing in the surf, was thrown with some violence against a post, striking the right arm and side. This was August 1st. The next day she suffered pain in the arm and a little soreness in the right side, but did not keep her bed. When first seen, on the sixth day, she was unable to move in bed without much pain in the right side of the abdomen, and she had extreme tenderness over a distinctly circumscribed space. She said the pain had been increasing every day since the accident. There was not the slightest discoloration or appearance of a bruise on any part of the body except the arm. There was some vomiting, with constipation, and tympanites. The temperature was 103° and the pulse 110. An enema was given to relieve the bowels, and aconite, followed by quinine, the latter drug was given in five-grain doses every two hours, but the temperature continued to rise steadily until it reached 105°, where it remained in spite of quinine, cold-sponging, and ice-bags on the head, for thirty-six hours. The evidences of peritonitis being confined to one side, a Leiter's coil, six inches in diameter, was placed on the side, and firmly bound there by a roller bandage. In four hours after the application of the coil, with a current of ice-water passing through it, the temperature had fallen to 102°, and in eight hours to 100°. The temperature of the water passing through the coil was increased to about 50°, and in twelve hours from its application the patient's temperature had fallen to 99°. The coil was removed, and in three hours the temperature went up to 103°. The coil was replaced, and it again fell to 99°. A second time, after twelve hours, the same experiment was tried, with the same result, the temperature reaching 103½°, and having an evident upward tendency. With these exceptions the coil was in position for two days and nights, after which time its removal was followed by a rise of only a degree, and its use was discontinued, the patient making a good but slow recovery. Ice-bags to the head were used at the same time with the coil. The water passing through the tube was sometimes ice-cold and sometimes only about 50°. The patient found the coil agreeable, and disliked to have it removed. The sensation of cold was decidedly pleasant the greater part of the time. When it was not so, the lump of ice was taken out of the bucket that supplied the coil, and the effect was no longer complained of. A soft handkerchief twice folded was placed between the lead coil and the skin. There was good reason to believe that an attack of general peritonitis was prevented in this case by the method adopted for reducing the temperature. Its use earlier would probably have saved the patient several days of suffering.

DR. C. S. WARD said that he was a great believer in this method of reducing the temperature. It was easily applied, was grateful to the patient, and the symptoms were mitigated, if not cut short. A great deal depended upon using it early.

DR. SAMUEL SEXTON reported some cases showing that there was a

RHEUMATIC ELEMENT IN CERTAIN AURAL TROUBLES.

He had noticed for several years a class of aural cases where the inflammation had not been very great, where

there was some redness of the drumhead, some deafness, and a feeling of stuffiness in the ear, but no pain. These symptoms had always been associated with a very severe "cold" in the head, which seemed to account for them. They had been usually in persons from thirty-five to forty-five years of age. Recently he had had a patient with a history of this kind, also with a history of rheumatism. He remembered that a London physician, Dr. Harvey, had said that rheumatic troubles sometimes affected the ear. By putting his patient under a treatment suitable to his rheumatic condition in addition to the management of the local conditions, which might vary somewhat in each case, there was very rapid improvement.

Dr. Sexton thought that a morbid condition of the ear might very often be noticed in rheumatic patients, but his recollection was that the cases reported by the London physician were chronic manifestations, whereas his own were subacute.

The PRESIDENT said that he had himself observed half a dozen cases of this kind.

Dr. W. T. Lusk related the history of a case illustrating the

VALUE OF THE FORCEPS IN BREECH PRESENTATION.

The patient was seen by Dr. Lusk in consultation with Dr. F. A. Castle. She had been married seven years and was thirty-two years of age. The six years of sterility had been due to antelexion and cervical stenosis. Dr. Castle had treated these conditions by dilatation, and pregnancy had followed. From the beginning the labor-pains were feeble, and the dilatation was dilatory. The child presented by the breech. Both extremities were reflected upward. The failure of all uterine action rendered artificial extraction necessary. Hooking the index fingers into the anterior and posterior thighs, was tried by both Dr. Castle and himself but without practical results. He then suggested forceps. An ordinary pair of the Simpson pattern were applied, with one blade over the sacrum, and with the other over the posterior surface of the opposing thigh. At the time of the application, the dilatation of the cervix was very nearly, but not quite complete, and the breech, though in the cavity, was at some distance from the perineum. The forceps held firmly. Little by little the breech was brought to the perineum and made to dilate the vulva. In the course of fifteen minutes from the beginning of the operation the woman was delivered of an eight-pound living child. An insignificant abrasion of the abdomen, which healed quickly, was the sole lesion inflicted by the forceps. Subsequently Dr. Castle found in the uterine walls, partly accounting for the tardiness of the labor, a number of small imbedded fibroids.

The PRESIDENT related the history of a case illustrating the

DANGER ATTACHED TO THE USE OF THE RED SOFT CATHETER.

During the present week two cases of empyema had been changed from the medical to the surgical side of the New York Hospital, for the purpose of removing fluid from the pleural cavity.

In the first case, a trocar and canula arranged like a tracheotomy tube were driven through an intercostal space in the axillary line. After the trocar had been withdrawn, the canula was attached to a piece of rubber tubing, which was carried into a closed bag partially filled with antiseptic sponges.

It was proposed that the second case should be treated in a somewhat similar manner. After the case was brought in, however, it was found that the second trocar had a sharp end and he was unwilling to leave it in situ. He was therefore obliged to remove the tube after having passed through it a small, red rubber catheter, previously unused, which was passed into the chest and secured by a suture passed through it and the adjacent skin, so that it could not slip in or out. The external

end was confined in a sponge-bag filled with antiseptic fluid. Next morning it was reported that the outer end of the catheter had broken off and that the inner end had slipped into the pleural cavity. He made an incision, opened the chest, and extracted it from alongside the spine.

The catheter that he had used was smaller than he would have otherwise employed, though while in it successfully drained off fifty-eight ounces of pus. The main point of interest was that it was one of the soft red rubber catheters, and these instruments are made red and particularly smooth by using red sulphuret of antimony. It was this which caused the white film that forms on the outside of them, and makes them after a short time hard and brittle by over-vulcanizing them. For this cause the not very rare accident occurs of their breaking in the urethra—though where the softening and swelling of the catheter prior to a break occurs, it is more likely due to an alkaline urine. Dr. Weir thought that the imported catheters were even worse than the domestic in this respect. The patient above referred to was not harmed but perhaps benefited by this free incision forced upon him.

Dr. Bull said that he did not think that catheters need be used at all in these cases, and it was better to discard them altogether. They are not made of durable materials, their walls are soft, and they are liable to be pushed in too far, or in the wrong direction. We have all that is necessary in the drainage-tube.

Dr. Bull related the history of a case in which an aspirator needle was broken off and about three inches of it left in the pleural cavity. Nothing was done and the patient got well.

Dr. G. F. Shradley referred to a similar instance with equally good results from the non-interference.

The Society then adjourned.

Correspondence.

OUR PARIS LETTER.

MIGUEL ON THE ASEPTIC ACTION OF CERTAIN CHEMICAL SUBSTANCES ON THE INFERIOR ORGANISMS.

PARIS, October 12, 1883.

In a work published last year by Dr. S. Miguel entitled "*Les Organismes vivants de l'Atmosphère.*" the author gives an account of the aseptic action of certain chemical substances on the inferior organisms termed bacteria. Dr. Miguel has since directed his attention to the study of other disinfectants, among which are included several powerful microbicides, and he has recently published the following table of the substances he experimented with, giving the weight in grammes, or fractions of grammes, of each substance capable of rendering imputrescible one litre of "bouillon," or beef-tea: Biniodide of mercury, 0.025; iodide of silver, 0.03; oxygenated water, 0.05; bichloride of mercury, 0.07; nitrate of silver, 0.08; osmic acid, 0.15; chromic acid, 0.20; iodine, 0.25; chlorine, 0.25; hydrocyanic acid, 0.40; bromine, 0.60; chloroform, 0.80; sulphate of copper, 0.90; salicylic acid, 1.00; benzoic acid, 1.10; chromate of potassium, 1.30; picric acid, 1.30; ammoniacal gas, 1.40; thymic acid, 2.00; chlorides of lead, cobalt, and nickel, 2.10; mineral acids, 2.00 to 3.00; binitrobenzine, 2.60; essence of bitter almonds, 3.00; carbolic acid, 3.20; permanganate of potassium, 3.50; aniline, 4.00; divers alums, 4.50; tannin, 4.80; sulphate of sodium, 5.00; arsenious acid, 6.00; boric acid, 7.50; hydrate of chloral, 9.50; salicylate of soda, 10.00; sulphate of the protoxide of iron, 11.00; amyl alcohol, 14.00; sulphuric ether, 22.00; butylic alcohol, 35.00; propylic alcohol, 60.00; borate of soda (borax), 70.00; ethylic alcohol, 95.00; sulphocyanide of potassium,

120.00; iodide of potassium, 140.00; prussiate of potash, 185.00; glycerine (official), 225.00; urea (natural), 260.00; hyposulphite of soda, 275.00; chlorate of soda, 400.00.

From the above list it may be seen that the biniodide of mercury takes the lead, and is capable of arresting the putrefaction of beef-tea at a strength of $\frac{1}{400,000}$; that is to say, one thousand times less than that of crystallized carbolic acid. The latter, which is reported to possess such powerful antiseptic properties, occupies a rather low position in the list, thymic acid being a great deal stronger. This being the case thymic acid might with advantage supplant the use of carbolic acid, which, besides its disagreeable odor, is so eminently toxic. A great number of the substances named have had aseptic properties attributed to them to a much higher degree than they were entitled to, but the above list gives them their proper place. Such, for instance, are chloral hydrate, salicylate of soda, the alcohols, borax, and the hyposulphite of soda. With regard to the last named substance, Dr. Miguel remarks that when mixed with some of the compound metallic disinfectants it has the curious faculty of considerably attenuating their microbicide properties. The antiputrescent properties of some of the essential oils have also been greatly exaggerated, the most popular of which are turpentine, lavender, aniseed, lemon, wintergreen, which, when added to animal fluids, do not stop putrefaction. Camphor and the mineral oils are in the same case, and Dr. Miguel explains this deficiency of the aseptic power of the substances of this class to their little solubility in water, the usual vehicle of putrescible matters.

The fatty alcohols and the hydrocarburets of the aromatic series are also, for the same reason, but poor disinfectants, although theoretically one would be led to suppose that they possessed highly antiputrid qualities. Certain perfumes, extracts of flowers, eau de cologne, etc., have little effect upon the microbes unless the liquids with which they are mixed contain a minimum of one-tenth of absolute alcohol. Aromatic and other vinegars possess, on the contrary, aseptic properties more precious in the sense that they prevent the development of bacteria in the media where pure acetic acid is not diluted to more than one-three-hundredth.

The proportions given in the above table represent the minimum quantities, which by experiment have been proved to be sufficient to prevent or suspend putrefaction, but for greater security Dr. Miguel recommends the dose to be doubled. From its high position as an antiseptic and in an economical point of view, corrosive sublimate certainly deserves more extensive application than it at present obtains, as a solution of $\frac{1}{100,000}$ is sufficient for ordinary prophylactic purposes, such as the washing of the hands before and after dissections, operations, and in most cases where such substances as borax or carbolic acid would be employed.

The substances referred to up till now act by paralyzing the evolution of the microbic germs and by destroying the adult bacteria, but they have no effect on the germs of the bacteria. Certain substances, however, have, by their chemical action, the power of completely destroying the germs of the bacteria, and to this class Dr. Miguel has applied the term "sporicides." The principal among these are the preparations of mercury and the salts of silver which in a solution of $\frac{1}{100,000}$ destroy in a few days the germs of microbes as surely as a dry temperature of 150° C. prolonged during several hours. Iodine, chlorine, and bromine, and the mineral acids come next. Sulphate of copper, so much vaunted as a microbicide, possesses this property only to a very limited extent, that is, it prevents the development of the microbes, but has no effect whatever on the germs themselves. But the microbicide "par excellence" is heat, which, raised to 110° C. for liquids, and to above 150° C. for solids, has been found sufficient effectually to destroy the germs of the microbes.

RANDOM NOTES AND OBSERVATIONS OF A TRIP THROUGH THE GREAT NORTHWEST.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR: Northern Dakota might be aptly called a cereal paradise. Yet partial nature has smiled upon its rolling prairies in a rather one-sided way. For miles and miles, stretching out endlessly to the far horizon the eye rests upon nothing but fertile plains. But there is a dead-level sameness about the scene that presently palls upon the sight. It is true, at first the astonished gaze receives a pleasant shock of newness in the boundless expanse of undulating golden wheat-fields. But it is all unrelieved by hill-top, tree, or river, so that the very vastness of this seeming ocean soon wearies through perpetual monotony. But while there is a lack of changeful romance in the scene, and picturesqueness too, is only conspicuous by absence, the thought rises imperative, that bounteous nature has here bestowed a gift of soil and climate that even now is a great blessing to thousands, and may, if judiciously managed, prove the same to untold thousands more. The unsurpassed fertility of the soil in this region appears to be due to a large deposit of vegetable mould over its surface. This invaluable accumulation varies in depth from two to six feet. A recognized authority in agricultural affairs has written the following, which seems no exaggeration of facts: "In view of the formation, extent, richness, and importance of the vegetable mould of our Northwestern prairies, it is established to a certainty that the United States is in possession of one of the greatest treasures in existence, which is not surpassed in value and importance by all the precious metals in the bowels of the earth."

An easily understood experience, but one not free from dangerous tendencies, is the brilliant success that has already attended the monopolist efforts of the so-called bonanza farms. The grand scale upon which wheat-growing is there conducted by a few enterprising men, threatens to speedily place the independent small farmer without the pale of possible competition. Before the surpassing agricultural interest of Dakota all other topics sink into comparative insignificance. Thus purely medical matters wear no specific features that might serve to distinguish the professional life of this vast territory from that of the new Northwest generally.

Fargo bustling with life and activity, where the electric light and horse-car have already entered and look as though they meant to stay; Jamestown, bright, cheerful, growing and spreading almost as you look upon it; Bismarck, the newly chosen capital of the territory, pleasantly and advantageously situated on the eastern bank of the Missouri, more substantial and sedate in appearance, as becomes its recently acquired dignity and importance; then Mandan, just beyond the great Missouri River bridge—Mandan which two years ago was but an Indian settlement, and is proud to-day of a white population numbering two thousand aspiring, ambitious, pushing heads—all these places, and many smaller ones, too numerous for mention, offer the competent practitioner of some experience a rather liberal reward for steady professional work. He must be quite familiar, however, with the various affections that a sturdy race of hard-working men are liable to, in spite of unusually healthful surroundings. Surgical skill is likewise requisite in some degree. The obstetrical forceps, guided by a steady hand, must find the right path and lock quickly.

At any rate it must not be too boldly employed as an effective perineal scythe. Moreover, the new doctor must be able to distinguish the sex of a catheter almost at the first glance. He must know how to examine a delicate, shrinking girl's tongue, without spoiling her prospects of language. He must not say an infant is "only teething," when it is only just dying of meningitis. Nor must he gravely speak of an affection of the lungs after a prolonged and painstaking auscultation of the liver. In a word, in addition to certain indispensable prerequisites, such as the ability to write at least three prescriptions

for one cough, he must be master of various minor accomplishments that your recent biannual graduate notoriously does not possess.

But quite seriously, as regards many of the filth-engendered pestilences of the metropolis, a sound ignorance of such maladies would seem to be, if not an aid, at least no hindrance to practice. From all of which it is apparent that while a man need not necessarily be a runner or racer in his profession, he must nevertheless be enough of a pedestrian to enable him to walk securely. But, by all means, let him first learn to stand on his own feet; for those intellectual appendages are not to be borrowed for love or money in the frontier towns of the new Northwest.

Before reaching Montana, an excellent view was had of a very remarkable region known as the Bad Lands. The peculiarity and grotesqueness of the many colored mounds and fanciful buttes that are there tumbled about haphazard for a distance of many miles, baffle all description. It is a scene that, following so closely upon the picture of abundance above alluded to, impresses one with a somewhat oppressive sense of waste and sterility. Nevertheless, the soil between the weird formations of the Bad Lands is said to possess excellent fertilizing purposes. Of course, the medical mind detects in these corrugated projections and bulging irregular formations, only multiple neoplasms on suffering nature's fair integument. One can easily fancy, scampering through these strange hills and valleys, herds of buffalo with the screaming red man in wild pursuit. However, all such fancies remain but pictures of the bewildered mind. For the buffalo has been recklessly slaughtered or driven away, and the Indian following, is compelled to live in reservations. So that at present the traveller feels constrained to lament the absence of both. They seem positively to belong there to complete the picture.

Into the formation of the territory of Montana there enters mountain, lake, and prairie, thus interesting the eye by a changeful scenery that has many elements of beauty. The average elevation very nearly approaches four thousand feet, and the climate possesses health-giving qualities. Severe winters are the rule, but the people apparently suffer less, and certainly complain much less of the cold, than is the rule with us.

If Dakota was styled a cereal paradise, Montana may justly claim the title of the Paradise of Miners. Glendive, Miles City, Billings, Livingston, Bozeman, Helena, and Missoula all make the impression of thriving places that mean to become still more prosperous in the near future. In most of these towns the cowboy is a feature, an institution, or an ever-present entity that may not be ignored. The first specimen of this numerous class elicits awe and admiration from the tenderfoot. Yes, the first cowboy is a decidedly imposing spectacle. After a while, however, he seems less grand, less picturesque, more human, and more dirty.

His physique is certainly good; powerful muscles, with plenty of solid bone to support them; a rather picturesque attire; a well-browned complexion; a reliable knife and pistol, under control of an unreliable temper, and often beyond it; a hardy horse or pony; finally, an antecedent history of whiskey, cards, and illiteracy. Such is the cowboy as he appears to the prejudices, perhaps, of an eastern observer. At any rate he scarcely improves upon more intimate acquaintance. He habitually chews vile tobacco, smells of viler liquor, and uses the vilest language.

Altogether he would seem to possess those delightful qualities that grace the successful metropolitan alderman, or some similarly accomplished politician. And now for the Indian. West of St. Paul, representatives of many different tribes begin to appear with rather startling frequency. The unpractised eye detects few differences amid a general similarity of shabby pride, deceitful cunning, stolid indifference except to bargains, and unwashed redness. Yet the knowing scout or grasping agent will promptly inform you that there exist among the various tribes and nations, differences in language, or at least

dialect, manners, habits, and beliefs, as well marked and deep seated as any that characterize the civilized peoples of the globe.

Sitting Bull, of infamous fame, when interviewed by your correspondent, was suffering from cephalalgia and an acute exacerbation of a chronic naso-pharyngeal catarrh. The choice Sioux in which this interesting information was conveyed to the admiring writer was interrupted by hideous grimaces, snorts, and sniffings quite touching to contemplate. Once a dangerous brigand, in whose restless, wandering eye fierce hatred of the white man still lurks, as if in ambush, his present occupation seems to be that of an innocent, peace-loving, autograph-writing society-lion. A strangely suggestive spectacle, nevertheless, to see the scion of European nobility hand-shaking with the chieftain of a dying race of savages. In that momentary grasp both may be dimly conscious of the levelling tendencies of our modern civilization, which pauses not in its destructive march onward and upward, till a plateau is reached where no prerogative exists, and only those fit to survive may rule themselves, their own sovereigns.

At Graycliff, a spot about midway between Billings and Livingston, the Crow Indians had turned out in great force to the number of about two thousand. Here a weird scene of wild excitement was enacted. It was a war-dance of the braves. Impossible to do justice to the fantastic costumes, the exultant whoops and shouts, the spasmodic gesticulations of gaudily painted nakedness that constituted the acute delirium of this extraordinary recurrent dance. It may sound incredible, but it is yet quite true, that the picturesque brokers at our stock exchanges are not much more noisy, and apparently demented, in their hyperbolic frenzy of speculative transaction than these poor uncivilized, down-trodden savages in the gyrations of a war-dance.

Ample opportunity was here afforded your correspondent to note some strictly professional matters. To begin with, the average Crow Indian is taller and more slim than the pale-face. Robust types of perfect physical manhood are rare. Womanhood is represented by spare squaws and sparer maidens. Not a single example of comfortably helpless obesity was discoverable. In fact, your mean Indian apparently glides through life without any adipose tissue at all. Consequently he never dies of a fatty heart.

The Indian bones are thin, not clumsy; the muscles have a wiry look and feel. They impart a sense of great power of resistance to fatigue. The absolute force of the Indian buck seems comparatively small, but the possibility of continuous steady effort is implied in his make-up. He could scarcely perform very trying labor; and yet where moderate strength is required he would not easily give out, outlasting probably the Caucasian and Chinaman.

A rather large proportion of Indians are pock-marked. Indeed, the notorious ravages of small-pox among these unvaccinated people constitutes an unanswerable argument in favor of compulsory vaccination. Syphilis appears to be no rarity among them. The writer saw numerous instances where this scourge had left indelible imprints on the bodies of its victims. Scrofula is apparently of equal frequency. Suppurating cervical glands, blear-eyes, and other characteristic signs are seen on many a fretful papoose and moping adolescent. Altogether, look at these Indians from what point of view you will, the conviction forces itself upon you that they are a degenerate and degenerating race which must needs suffer extermination at the hands of inexorably progressive civilization. Whatever else manifest destiny may signify, for the Indian it means the doom of inevitable extinction. Soon they will live nowhere on earth save in the traditions of the poet, or the colder remembrance of the historian. And let us own that fate is no more cruel to them than to inferiority generally, in a world where superiority alone escapes dripping through the narrowing sieve of competitive life. This letter has already exceeded the limit intended for it. Your corre-

spondent is, therefore, constrained to reserve for a final one a few remarks about Washington and Oregon, and the Yellowstone National Park.

Very respectfully yours,

EDMUND C. WENDT,

126 WEST THIRTY-FOURTH STREET, NEW YORK, October 29, 1883.

Army and Navy News.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from October 20 to October 27, 1883.

MOORE, JOHN, Lieutenant-Colonel and Assistant Medical Purveyor. To be relieved from duty as Medical Director, Headquarters Department of the Columbia, to proceed to San Francisco, Cal., and assume charge of the medical purveying depot in that city. S. O. 243, par. 10, A. G. O., October 24, 1883.

HORTON, S. M., Major and Surgeon. Leave of absence for one month, with permission to apply for an extension of three months. S. O. 216, par. 6, Department of the Missouri, October 20, 1883.

WOLVERTON, WILLIAM D., Major and Surgeon. Granted leave of absence for one month. S. O. 201, par. 6, Department of the East, October 24, 1883.

BARNETT, RICHARDS, Captain and Assistant-Surgeon. Assigned to duty at Columbus Barracks, Columbus, O. S. O. 240, par. 1, A. G. O., October 20, 1883.

MERRILL, J. C., Captain and Assistant-Surgeon. Granted leave of absence for one month. S. O. 201, par. 7, Department of the East, October 24, 1883.

MAUS, LOUIS M., Captain and Assistant-Surgeon. Assigned to duty at Fort A. Lincoln, D. T. S. O. 180, par. 4, Department of Dakota, October 15, 1883.

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service, from July 1, 1883, to September 30, 1883.

BAILHACHE, P. H., Surgeon. Detailed as member of board to examine candidates for promotion, August 23, 1883. Detailed as Surgeon-in-charge, Cape Charles Quarantine Station, September 5, 1883.

MILLER, T. W., Surgeon. Granted leave of absence for twenty-five days, August 31, 1883.

WYMAN, WALTER, Surgeon. Detailed as member of board to examine candidates for promotion, Aug. 23, 1883.

LONG, W. H., Surgeon. Granted leave of absence for twenty days, September 25, 1883.

SMITH, HENRY, Surgeon. Directed to take charge of quarantine service at the Capes, July 29, 1883.

STONER, G. W., Passed Assistant Surgeon. Granted leave of absence for thirty days, August 24, 1883. To inspect the relief stations along the coast of Maine, September 29, 1883.

GOLDSBOROUGH, C. B., Passed Assistant Surgeon. Granted leave of absence for thirty days, August 29, 1883.

BANKS, C. E., Assistant Surgeon. Relieved from duty at Portland, Or., and to report to the Surgeon-General at Washington, July 10, 1883.

CARMICHAEL, D. A., Assistant Surgeon. Granted leave of absence for ten days, August 31, 1883.

PECKHAM, C. T., Assistant Surgeon. To proceed to Portland, Me., for temporary duty, August 25, 1883.

DEVAN, S. C., Assistant Surgeon. To proceed to Portland, Or., and assume charge of the service, September 11, 1883.

KALLOCH, P. C., Assistant Surgeon. To proceed to Philadelphia, Pa., for temporary duty, July 25, 1883. To rejoin his station (New York), July 31, 1883.

YEMANS, H. W., Assistant Surgeon. Relieved from duty at Sitka, Alaska, and to proceed to Portland, Or., for temporary duty, July 10, 1883. To proceed to San Francisco, California, reporting for duty to Surgeon Vansant, September 11, 1883.

GLENNAN, A. H., Assistant Surgeon. To remain at Norfolk, Va., until further orders, July 29, 1883.

WASDIN, EUGENE, Assistant Surgeon. To proceed to New Orleans, La., for temporary duty, August 2, 1883. To proceed to Mobile, Ala., for temporary duty, August 27, 1883. To rejoin his station (New Orleans) as soon as practicable, September 25, 1883.

GUITÉRAS, JOHN, Passed Assistant Surgeon. Promoted and appointed Passed Assistant Surgeon by the Secretary of the Treasury, from September 1, 1883; August 31, 1883.

WHEELER, W. A., Passed Assistant Surgeon. Promoted and appointed Passed Assistant Surgeon by the Secretary of the Treasury, from September 1, 1883; August 31, 1883.

O'CONNOR, F. J., Assistant Surgeon. Resignation accepted by the Secretary of the Treasury, to take effect August 1, 1883; August 2, 1883.

WASDIN, EUGENE, M.D., of South Carolina, having passed the examination required by the Regulations, was appointed an Assistant Surgeon by the Secretary of the Treasury, August 2, 1883.

Official List of Changes in the Medical Corps of the Navy, for the week ending October 27, 1883.

VAN REYPEN, W. K., Surgeon. Detached from the Naval Hospital, New York, and ordered to the U. S. Ship Powhatan.

WELLS, H. M., Surgeon. Detached from the Naval Laboratory, New York, and ordered to the Naval Hospital, New York.

GORGAS, A. C., Medical Inspector. Orders modified so that he will be detached from the Naval Hospital, Chelsea, Mass., on December 10th, instead of November 10th.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending October 30, 1883:

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
<i>Cases.</i>								
October 23, 1883.....	0	59	45	1	13	38	0	0
October 30, 1883.....	1	61	55	6	29	43	0	0
<i>Deaths.</i>								
October 23, 1883.....	0	20	12	1	2	20	0	0
October 30, 1883.....	0	22	9	5	7	28	0	0

THE VERMONT STATE MEDICAL SOCIETY held its annual session at Montpelier, October 11th and 12th, about fifty physicians being present. Papers were read by Dr. O. W. Sherwin, on "Jaundice;" by Dr. L. M. Bingham, "Dilatation of the Oesophagus;" Dr. E. R. Campbell, on "Hernia;" Dr. S. J. Allen, on "A New Method of Localizing Bullets;" Dr. S. T. Brooks, on "Duties and Rights of Experts;" Dr. O. W. Sherwin, on "Physicians' Testimonials;" Dr. John B. Wheeler, on "Venesection." The following officers were elected for the ensuing year: *President*—S. S. Clark, St. Albans; *Vice-President*—C. M. Rugg, Hartland; *Secretary*—J. S. Richmond, Woodstock; *Treasurer*—Sumner Putnam, Montpelier; *Auditor*—C. M. Chandler, Montpelier; *Delegates appointed to attend American Association*—Drs. C. M. Chandler, Montpelier; C. L. Allen, Rutland; L. M. Bingham, Burlington; E. F. Upham, Randolph.

THE EPIDEMICS AT THE NEW YORK INFANT ASYLUM AND THE REPORT OF THE MEDICAL BOARD.

IN view of the frequent sensational newspaper reports of the recent epidemics at the Mount Vernon branch of the New York Infant Asylum, and on account of certain partial statements in the medical press, the following report is made public :

To the Board of Managers of the New York Infant Asylum :

Pursuant to the request of the Medical Board, we, the visiting physicians of the Mount Vernon Branch, respectfully submit the following report of the history and management of the epidemics of measles, whooping-cough, and diphtheria recently prevailing there :

Whooping-cough existed during July and August. Up to this time there have been 83 cases of that disease, and 17 deaths from it. Every one of these 17, however, also had measles. Measles appeared early in August, and the following is the tabular statement of our experience with that disease :

Children in the institution August 1st	224
Received subsequently	12
	236
Number of individuals who had measles	203
Number of children who escaped	33
The recurrences of the rash, with all the accompanying symptoms of the disease, was a marked feature.	
124 had measles twice	248 cases.
34 had measles thrice	102 "
1 had measles five times	5 "
44 had measles once	44 "
3 (adults) had measles once	3 "
Total measles	402 "
Whooping-cough	83 "
Diphtheria	10 "
Entero-colitis	70 "
Total in asylum	565 "

Deaths.

Measles alone	none.
Diphtheria, complicated and convalescent from measles	6
Measles, complicated with whooping-cough, pneumonia, entero-colitis, etc.	48
Total	54

Since August 1st there have also been 18 deaths in children, showing no symptoms of either measles, whooping-cough, or diphtheria, as follows: Pyæmia, 1; dysentery, 4; phthisis, 2; marasmus, 1; bronchitis and inanition, 1; capillary bronchitis, with catarrhal enteritis, 1; acute meningitis, 2; cholera infantum, 6

Total	72
Per cent. of inmates (children)	30.51
Per cent. of cases of all diseases	12.75
Per cent. of complicated measles cases	11.93

The average mortality, according to the best authorities is, of

Measles	12 per cent.
Diphtheria	31 "
Diphtheria, complicated with whooping-cough	95 "

Rilliet and Barthez report an epidemic of measles occurring in an hospital where the mortality was over sixty-seven per cent.

The complications causing death were as follows: Broncho-pneumonia, croupous pneumonia, capillary bronchitis, bronchitis, acute meningitis, whooping-cough, diphtheria, entero-colitis.

In view of the severity of the diseases with which the Home has been afflicted, and on account of the harsh and unscientific criticism to which the general management has been subjected, a somewhat detailed statement may not be out of place.

While there appear to be several sources from which the diseases were introduced to the asylum, there is no certainty respecting any of them. It is sufficient for us to remember that it is a common experience in similar institutions, and that when one of these contagious affections prevails, the others are pretty sure soon to appear. It is a recognized fact among authorities, with respect to whooping-cough, measles, and diphtheria, that, given an epidemic of one of them, the others will ensue and complicate the results. The rule is for whooping-cough to appear first, this to be followed by measles, and finally, toward the decline of the first two, diphtheria comes in a relatively small proportion of cases. This sequence is exactly what we have experienced at Mount Vernon.

The Home at Mount Vernon is attractively situated upon an elevated site on the White Plains turnpike. It consists of a large main building and five outlying cottages, besides an old residence. The main building is three stories high, and is used for the quarters of the resident officers (matrons and physicians), drug store, parlors, etc. It contains also four wards, three large, about 75x20 feet, and one smaller. The cottages, with one exception, are two stories high; one is three. There is also a "Sanitarium," or play-room; a one-story cottage inclosed with glass. In every instance except one there is only one room on a floor, constituting a ward, and accommodating from ten to thirty children.

The regularly appointed visiting physicians were Drs. Ripley and Conant. The former found it inconvenient to officiate, and resigned. The latter made several visits to the asylum during this epidemic, when he was called out of town to attend a sick relative; he subsequently resigned. At the request of the President of the Board of Managers, Dr. E. A. Goodridge, of Flushing, one of the managers, kindly consented to act *ad interim*. In the meantime, Dr. Caroline Marr, the resident physician, had had frequent and timely aid and counsel, we learn, from Drs. Joel Foster, Blakeman, and Burrall, members of the Executive Committee of the Board of Managers. Dr. F. M. Warner, formerly resident physician at the Nursery and Child's Hospital, was appointed attending physician about September 25th, and since October 3d has been making daily visits.

At the request of the Medical Board, Dr. Fowler, who is attached only to the Sixty-first Street branch, co-operated with Dr. Warner, and has visited the asylum with him almost every day since October 5th.

On October 10th Dr. Edward Bradley, having been appointed visiting physician to fill the remaining vacancy, began his visits, and up to the present time the asylum has been regularly and faithfully attended by these three, working in perfect accord.

The conditions to overcome which we met were those growing out of the most severe epidemic of measles, whooping-cough, and diphtheria, and, above all, the practical difficulties in the way of successful isolation. That is to say, there were twelve classes of children to be kept separate: (1) Measles; (2) measles with whooping-cough; (3) whooping-cough; (4) convalescent measles; (5) doubtful whooping-cough; (6) doubtful measles; (7) those who had been exposed to measles; (8) those who had been exposed to whooping-cough; (9) diphtheria; (10) doubtful diphtheria; (11) whooping-cough and diphtheria; (12) healthy children.

Now, although we had about thirteen wards, we could in only a few instances utilize both wards of a cottage,

because occupancy of either floor would infect the other, having at one time over one hundred cases of measles on hand. Sad experience from the beginning taught us this. Then, again, one cottage was generally empty undergoing thorough disinfection. In the emergency, therefore, we erected three tents, capable of accommodating four patients each. These tents had tight board floors raised four inches from the ground, and were warmed by stoves. A thermometer was hung in each, and the temperature easily maintained at about 68° F. Into two of these tents we put our diphtheria cases. Into another the measles which cropped out among the cases afflicted with other diseases. The third tent was used as a quarantine for the physician and nurse attendant upon the diphtheria. No outside communication was allowed except that which might arise from a specially detailed attendant who delivered the meals and medicines. The sight of the tents excited the indignation of the local Board of Health, who came one night and ordered our patients removed to a cottage occupied by the farmer's family. This procedure we reversed two days afterward. Hence a conflict of authority and unfriendly reports.

At present there are six cases of acute disease in the asylum: three diphtheria, two capillary bronchitis, one measles. *No case of scarlet fever has occurred in the institution.*

Dr. A. N. Bell, the regularly appointed sanitarian, has been in constance attendance since September 29th, and has perseveringly superintended in detail all matters pertaining to isolation, disinfection, ventilation, heating, water supply, drainage, etc.

We have had four trained nurses constantly on duty, besides those regularly employed.

The house physician, Dr. Caroline G. Marr, and her assistant, Dr. Otis, merit high praise for their untiring zeal and perseverance under circumstances the most trying. So far as we have been able to judge, Dr. Marr has shown herself competent to fill her position, for which she was examined and recommended by Dr. J. Lewis Smith.

Those familiar with the statistics of similar epidemics will see that our mortality has been under the average.

In our opinion, the total mortality is not excessive when we consider the following points: The epidemic was in an asylum; measles of a severe type supervened in children already debilitated and still crippled by the lung complications of whooping-cough, the remarkably frequent repetition of the measles, and, finally, the advent of malignant diphtheria.

We may be permitted to add the regret that our work, arduous though it has been, does not seem to meet the approval of the local Health Board or the coroner, all of whom persist in attempts to question our diagnosis, treatment, and general management.

Very respectfully,	
GEO. B. FOWLER, M.D.,	} <i>Attending</i> <i>Physicians.</i>
A. N. BELL, M.D.,	
E. BRADLEY, M.D.,	
F. M. WARNER, M.D.	

OCTOBER 25, 1883.

We, the undersigned, members of the Medical Board of the New York Infant Asylum, approve of the above report. Oren D. Pomeroy, M.D., Henry G. Piffard, M.D., J. Clarke Thomas, M.D., C. L. Dana, M.D., William J. Morton, M.D., F. H. Bosworth, M.D., J. Lewis Smith, M.D., W. R. Birdsall, M.D., H. Marion Sims, M.D., W. F. Mittendorf, M.D.

DANGER FROM FLIES.—Dr. Grassi is said (*British Medical Journal*) to have made an important, and by no means pleasant, discovery in regard to flies. It was always recognized that these insects might carry the germs of infection on their wings or feet, but it was not known that they are capable of taking in at the mouth such objects as the ova of various worms, and of discharging them again unchanged in their feces. This point has

now been established, and several striking experiments illustrate it. Dr. Grassi exposed in his laboratory a plate containing a great number of the eggs of a human parasite, the *trichocephalus dispar*. Some sheets of white paper were placed in the kitchen, which stands about ten metres from the laboratory. After some hours, the usual little spots produced by the feces of flies were found on the paper. These spots, when examined by the microscope, were found to contain some of the eggs of the *trichocephalus*. Some of the flies themselves were then caught, and their intestines presented large numbers of the ova. Similar experiments with the ova of the *oxyuris vermicularis* and of the *tenia solium* afforded corresponding results. Shortly after the flies had some mouldy cream, the *oidium lactis* was found in their feces. Dr. Grassi mentions an innocuous and yet conclusive experiment that every one can try. Sprinkle a little lycopodium on sweetened water, and afterward examine the feces and intestines of the flies; numerous spores will be found. As flies are by no means particular in choosing either a place to feed or a place to defecate, often selecting meat or food for the purpose, a somewhat alarming vision of possible consequences is raised. Dr. Grassi invites the attention of naturalists to the subject, and hopes that some effectual means of destroying flies may be discovered.

TANNATE OF SODIUM IN CHRONIC NEPHRITIS.—Tannate of sodium has been recommended by Lewin instead of tannin in albuminuria, in order to lessen the excretion of albumen. It has been tried by Ribbert on animals. Ribbert ligatured the renal artery in rabbits for an hour and a half and produced albuminuria. He then injected a one-half per cent. solution of tannin into the jugular vein, extirpated the kidney, and examined it microscopically. He found that much less albumen occurred in the glomeruli when tannin was employed, showing that it had lessened the excretion of albumen. A similar result was obtained with tannate of sodium, and in his experiments with this substance the albumen was generally completely absent from the glomeruli. Dr. Briese has tried the tannate of sodium upon patients suffering from chronic albuminuria. He finds that some patients bear it well, and can take it for a month without any disagreeable consequences, while others vomit after every dose, and in others again the stomach and intestine are affected in two or three days. In the four carefully observed cases which he records the tannate of sodium was of no use whatever. It did not lessen the quantity of albumen excreted, nor did it alter the course of the disease.—*Deut. Arch. f. klin. Med.*, vol. xxxiii., p. 220.

TREATMENT OF PREMATURE BALDNESS.—Dr. Lassar contends (*Berliner klin. Wochenschrift*) that premature baldness is the result of contagion, and not of any general condition of the health. The method of treatment recommended is as follows: The scalp is to be washed every day with tar soap, or soft glycerine soap, or with soap containing sodium iodide; the soap is to be thoroughly applied, and rubbed into the scalp for fifteen minutes. Following this, a warm douche is used; then after the application of a corrosive sublimate solution (two parts in one thousand) the hair is dried, and a half per cent. spirit solution of naphthalin is rubbed into the affected parts. Carbolic or salicylic acid may also be employed. If this treatment be adopted in the early stage, when the hair is just beginning to fall, it usually proves successful, but it must be kept up for eight weeks or more. The fact that this disease is due to a communicable morbid principle suggests that it may be conveyed by the comb and brush of the barber.

RESORCIN AS AN ANTIPYRETIC is not so good as quinine of salicylate of soda, says Dr. Sarbeck, on account of the nervous symptoms which it produces. It quickly reduces temperature and causes perspiration. It is given in fifteen-grain doses.

ACTION OF MINERAL WATERS AND OF HOT WATER UPON THE BILE.—Lewaschew and Klikowitch, from experiments upon dogs, conclude that the use of ordinary alkaline mineral waters was to increase the quantity of bile and to make it more fluid and watery. This increased flow is beneficial in clearing out any bile stagnating in the gall-bladder. A subsequent increase in the quantity of bile indicates a greater flow of bile into the gall-bladder, and this also is of service in emptying out any stagnant bile, and restoring the normal condition when this is disturbed. Artificial solutions of alkaline salts were found to have a similar action to the natural mineral waters, and, as with them, the action varies according to the concentration of the solution. Bicarbonate of sodium has a quicker, more powerful, and more lasting effect on the composition of the bile than the sulphate of sodium, and weak solutions than strong ones. Vichy was more efficacious than Carlsbad water. Hot water was found to have an effect on the bile much like that of the mineral waters.

THAT MANY ANEURISMS are the result of nervous influence is the conclusion of Dr. Lewaschew. This observer found that after constant irritation of a nerve, the middle coat of the arteries in its area of distribution became sclerosed and united to the intima, a condition exactly like that found in the development of aneurismal dilatations.

THE New York Planet of October 15th comes to us in a new dress, and is much improved in appearance. Its page is enlarged and the general size of the journal increased. It contains six original articles, a good report of the recent meeting of the New York Academy of Medicine, editorials, and miscellaneous news. Its editor, Dr. C. E. Nelson, has our best wishes for the success of his enterprise. The journal contains twelve double-column pages, RECORD size, and is published monthly at one dollar per year.

SUICIDE OF A NEW YORK PHYSICIAN.—Dr. Walter L. Foley, of this city, committed suicide on October 20th by taking morphine. He was only twenty-seven years of age, and graduated from Bellevue Hospital Medical College in 1877. He practised in California for two years, and then came to this city. Although a bright student and clever practitioner, he did not succeed in his profession, as his habits were shiftless and thriftless, and he quickly lost the patients that it had taken him a long time to secure. Finally he became addicted to the opium habit, and this entirely ruined him and his prospects. It is only about two years since another young physician living near the city ended his career in a very similar manner.

DR. H. S. TANNER, of fasting fame, was arrested last week at Jamestown, N. Y., on a charge of not being properly registered in the County Clerk's Office. He had a diploma from the Eclectic Medical Institute dated February 2, 1859, indorsed by the United States Medical College, of New York, which is not a legal institution. Dr. Tanner is the third eclectic physician who has been arrested there recently on information lodged by the Secretary of the Chautauqua Board of Censors. He claims it is an effort of the regulars to suppress the eclectics and intends to make this a test case.

THE ORIGIN OF THE EGYPTIAN CHOLERA is still a matter of dispute, according to a correspondent of the *Medical Press and Circular*. The English continue stoutly to maintain that it originated *de novo* in Damietta. Some of the French have also taken that view. Dr. Grant Bey and many others, however, believe it to have been imported from Asia.

DIGITAL DIVULSION IN GASTRIC STENOSIS.—Professor Loveta has recently performed for the fourth time the operation of digital divulsion of the pylorus for stenosis. The patient was cured.

THE NATIONAL WHOLESALE DRUG ASSOCIATION met last week in this city. At one of the sessions Mr. Meyers, of Cleveland, read a report of the Committee on Proprietary Articles. He spoke of the importance of this branch of the trade, more than one-third of the entire sales in the drug market consisting of patent medicines. Mr. C. B. Allaire, of Peoria, read the report of the Committee on Adulterations, in which, and in the course of the discussion which followed, were developed many tricks of the trade, such as mixing castor-oil with oil of lemon, and corn meal and wheat flour and buckwheat flour with powdered drugs. The committee deplored the increased adulteration of wines and brandies, and urged members of the association to sell none but pure drugs. A dinner was given in the evening at Delmonico's.

HONORS TO MR. LISTER.—Professor Lister has been visiting the city of Buda-Pesth, and has been received with great honor by the profession and students there. A banquet and torch-light ovation were tendered him, accompanied with addresses of welcome, cheers, and congratulation.

WOMEN AS DRUGGISTS.—Six ladies have distinguished themselves, says the *London News*, as students in the South London College of Chemistry, where they have been studying with a view to pass the examinations of the Pharmaceutical Society. They mean to begin life as druggists, and we believe they are the first women who have been trained in a public school for the business of pharmacy. They will assuredly deserve credit for their enterprise, for if they succeed they will have done good service in widening the area of possible employment for women. It has often been matter for surprise that ladies did not select pharmacy as a fair field for the exercise of their talents in winning an honorable livelihood. The trade is a profitable one; in fact, the old saying in the country used to be that the druggist's shop was the only one in the village where every shilling taken in the till earned 11d. for the master. The work of preparing and compounding medicines is also neat and delicate—indeed, the Americans have almost elevated pharmacy to the dignity of a fine art in these later days. It is light, and cannot by any pretence be termed “unwomanly”—so that there ought to be no social prejudice against it. The only possible objection to women as pharmacists would rest on their implied inability to acquire the scientific knowledge necessary for safe practice. But that objection the six lady students who have stood so well in their classes at the South London School of Chemistry have personally disproved; besides, it is not necessary to license any woman as a druggist unless she has the requisite scientific qualifications. In these days, when people suffer as much anxiety about the employment of their girls as of their boys, the discoverer of a new occupation for women is a public benefactor.

CLINICS AT THE SCHOOL OF OPHTHALMOLOGY, OTOLGY, AND LARYNGOLOGY OF THE NEW YORK EYE AND EAR INFIRMARY.—A “subscriber” writes: “Please correct what is doubtless an unintentional error in your published ‘Schedule of the Various Clinics to be held in New York City the coming Season,’ in regard to the clinics held at the School of Ophthalmology, Otolgy, and Laryngology of the New York Eye and Ear Infirmary. You announce one clinic only at that institution, where there are three or four held daily, as follows: Eye clinics at 2 P.M. on Monday, 1.30 P.M. on Tuesday, 2 P.M. on Wednesday, 1.30 P.M. on Thursday, 2 P.M. and 3 P.M. on Friday, 1.30 P.M., 2.30 P.M., and 3.30 P.M. on Saturday. Ear clinics at 3 P.M. and 4 P.M. on Monday, 3.30 P.M. on Tuesday, 4 P.M. on Wednesday, 3 P.M. and 4 P.M. on Thursday. Throat clinics: 1.30 P.M. on Tuesday and at 3 P.M. on Wednesday. By inserting the above it is hoped that many who have read the advertisement of this school in the widely-circulated pages of THE RECORD may not be misled.”

MALARIA AS AN ETIOLOGICAL FACTOR IN NEW YORK CITY.

By SIMON BARUCH, M.D.,

NEW YORK.

THE day of system-building in medicine has passed away. The hammer of skepticism has dealt sturdy and effective blows to the pretentious systems which have from time to time been erected by self-constituted authorities.

The history of medicine reveals the fact that in days of yore medicine represented a vast empire, ruled by the great monarchs, whose thrones rested upon university chairs and whose dicta were promulgated by satraps and underlings with reverence, and followed by the masses with pious zeal.

To-day medicine represents a great republic, in which "the people rule." Under this regime there exists no authority whose leadership is recognized with unquestioning obedience. No learned professors weave ingenious theories to serve as unerring guides to the masses. But there is a silent and no less potent influence "leading" the minds of the profession, especially in this section of our country; fashion finds zealous votaries in our ranks and exacts unquestioning obedience among a large following.

The discussion of a potent therapeutic fashion of the day and its bearings upon physician and patient forms the theme of this paper.

Sixty years ago the renowned Hufeland¹ wrote, "It is really remarkable that, just as we have escaped from the *opomania*, a real *hematomania* has risen among us. A veritable thirst for blood has overpowered some physicians, and of many it may be said, as of the ancient gods, they cannot be propitiated except by the sight of blood. The loss of blood is no longer reckoned by ounces but by pounds; every headache, every indigestion, is sufficient ground for abstraction of blood." In France an esteemed author, Audin-Rouvière² re-echoed Hufeland's philippics against blood-letting. "The leech fury," he says, "is carried so far that every mild headache, every slight palpitation, the slightest indisposition demands the presence of the physician, who at once orders leeches," etc. "*Chaque siècle a son goût particulier et sa mode*," says this brilliant writer. And he says truly.

To-day the taste and fashion have changed indeed, although not a century has passed over our heads. The "phlogozelotismus" of Hufeland's day has been succeeded, in our country at least, by a *malario zelotismus*, and the *hematomania* which was the baneful offspring of the former has been succeeded by a *quinomania*, which happily does not equal its predecessor in pernicious effect.

To-day quinine rivals the blood-letting of a former period in its universality of application in the treatment of disease.

Among purely medicinal articles this drug exceeds all others in the quantity manufactured and imported into this country. Quinine is to-day the greatest "staple article" among medicines in the commercial world. Every large drug house presents special claims for its

own preparations of the cinchona alkaloids. In the show-windows of the retail druggist quinine is heralded as a panacea, in various seductive forms. Pills, capsules, compressed powders, tablets, elixirs, syrups of quinine are regularly sold to the anxious seeker after health without a physician's prescription. A schedule of prices may be seen prominently displayed in the windows of many druggists, offering quinine pills as the grocer offers eggs. The jaded pleasure-seeker, the wearied merchant, the excited speculator, the hard-worked literary man, the pallid clerk, the nerveless seamstress; men and women in all conditions of life resort to quinine when suffering any of those undefined and undefinable ailments due to their vicious modes of life. Few cases come under the observation of the physician which have not been dosed with quinine.

A credulous public seeks in this agent an unfailing remedy for a large catalogue of diseases. Malaria is supposed to be the omnipotent, ubiquitous enemy lurking in every household. In the luxurious dwellings of the rich as well as in the humble tenements of the poor, in the crowded schoolhouses, in the prisons and court-rooms, in the railway stations, in the beautiful parks of this great city, and even in its snow-clad streets, at every point "where people do congregate," malaria is believed to contaminate the air with its noxious elements, and quinine is trusted to exorcise this potent yet hidden terror! *This popular idea has originated in the reckless diagnosis of malarial fever by many physicians, and the facile resort to quinine in all diseases characterized by an elevation of temperature.*

The comparison of a notable "Compend of Medicine," written by Professor Nathaniel Chapman fifty years ago, with a similar work published a short time ago, offers an illustration of therapeutic fashion. In Dr. Chapman's book, the stereotyped recommendation under the head of treatment was, bleeding, leeches, mercury; the modern compend bears the stereotyped legend, quinine, food, stimulants. The lay as well as the professional mind is now so thoroughly imbued with the omnipotence of malaria as an etiological factor that we are rapidly approaching the adoption of the views of Macculloch, a vigorous malaria maniac, who wrote a work¹ of considerable merit, but which failed to leave an impression by reason of his extreme views. This author delineates the prevalence of the "typhus fashion," against which he delivers himself as follows (p. 26): "From an unfortunate blindness as to the existence or presence of malaria or its causes, added to the want of reflection among the mass of routine practitioners and perhaps not a little aided by the now popular and vulgar use of the term typhus, it is almost the invariable usage, not merely of the people, but of the generality of practitioners, to give this term to every continuous marsh fever; and not only so, but more inexcusably to apply it even where the most ordinary discernment and reflection would indicate a true remittent." How nearly the views "of the people and the generality of practitioners" of the present time, in this country, and especially of this city, approximate to those of Macculloch, will be evident from a few quotations from his work. On page 50 he says: "Remittent fever may be found with scarcely any marked symptoms, as muscular weakness, at times not even the appetite seems affected." On page 31 he refers to con-

¹ Journal der practischen Heilkunde, p. 5. Berlin, 1824.

² Audin-Rouvière: Plus de Sangsues! Paris, 1827.

¹ Essay on Remittent and Intermittent Diseases. London, 1828.

stipation (!) as follows: "In the whole catalogue of ordinary practical errors I know few indeed more common than that which views a sluggish state of the bowels as a primary disease, sometimes also as a consequence of theoretic disorders of the liver, instead of considering it what it really often is, the produce of a febrile state, belonging either to the fever or some other initiative and similar cause" (malaria). He dwells with equal emphasis on malaria as the chief cause of a formidable catalogue of maladies, among which he enumerates delirium (p. 61), hectic (p. 41), debility, rheumatism (p. 370), diarrhoea (p. 390), hay fever, catarrh (p. 344), palpitation of the heart (p. 359), palsy of the heart (p. 359), hysteria (p. 85), climacteric diseases (p. 304), lethargy and drowsiness (p. 76), mental diseases (p. 331), suicidal mania, etc. "Were I to pursue the illustrations of every disease which occurs as a symptom in the anomalous and obscure fever arising from malaria, I should write a universal treatise on physics," he says on page 87. Does not the tendency of "the people and generality of practitioners" seem to be in the direction of these views to-day? Are not many of the disorders which Macculloch classes as malarial to-day ascribed to malaria by the people and, unhappily, also by some members of the profession? Lest the picture should appear overdrawn, I will mention that only a few weeks ago a case of suicide, reported in the newspapers, was gravely charged to malaria as the cause! Still more recently a prominent physician of this city was treated for malaria, when it was discovered that he was really suffering from the initiatory symptoms of general paresis.

Witness, also, the five to six hundred *deaths* annually ascribed to malarial fever in New York, a city far remote from the tropics.

Witness, also, the immense consumption of quinine and its preparations, as an antidote to the malarial poison. The typhus mitior, synocha and synochus of Cullen, were the fashion of Macculloch's day. He endeavored to convert the "blind followers" of Cullen to his more fanatical universal malaria doctrine, but he failed at that time. Are the seeds sown by Macculloch germinating to-day?

It would be a quixotic enterprise to attempt to win the profession over from the dominant malarial idea of many cases of fever to any other *universal* etiological view. Far be it from me. It is my aim to "hold the mirror up" to my confrères, to sound a note of warning, and chiefly to *urge most earnestly a more careful diagnosis of febrile disorders, especially as they prevail in populous districts and cities.* It would be profitable to subdue somewhat that spirit of self-satisfaction and overweening confidence with which the vast improvements in physical diagnosis, aided by chemical and mechanical discoveries, have imbued the modern professional mind. *The symptomatology of disease requires a more attentive study.* The example of the old masters in medicine may be profitably emulated to-day. When we read the correct delineations of many diseases to be found in the writings of Hippocrates, Galen, Aëtius (who was so freely followed by Shoenlein and his scholars, Eisenmann, Buzonini, Canstadt, and others of a later day), and of Prosper Alpinus (who is justly called the father of semeiology), of Boerhaave, Van Swieten, Sydenham, Fr. Hoffman, and Gaubius, we trace the master hand in every touch of the picture drawn from nature. Relying upon their own personal observations, they scanned with scrutinizing eye the history, critical periods, the temperature, pulse, respiration, tongue, facies, and secretions. Following their example and aided by the modern methods of precision, how vast would be the vantage-ground of the physician of the present time in facility of attaining a correct diagnosis and consequently a more successful therapeutics! The fevers of our country have been carefully and conscientiously studied by Drake, Bartlett, Mitchell, Wood, and others. These authors have furnished us a complete semeiology of malarial fevers, which it will be profitable

to study at the present time. The dissemination of the idea that malaria is a predominant element in the etiology of a large number of diseases in our cities (and the abuse of quinine as a remedy as a result thereof) is due to two causes, viz.: errors of diagnosis, resulting from an imperfect appreciation of the manifestations of true malarial fevers, and, secondly, the erroneous recognition of typho-malarial fever as a true malarial disease. It is the object of this paper to contribute to a more correct appreciation of malarial fevers by pointing out the errors of diagnosis, as illustrated in the "Records of the Board of Health" of New York City, and in a subsequent portion to devote attention to the differential diagnosis of true malarial fever from diseases simulating them.

The conclusions of this essay are based upon observations made during a public and private practice of twenty-one years. The first three years of this period were passed in active service as a military surgeon in the camps of Virginia; the succeeding fifteen years were spent in an extensive practice at Camden, S. C., and upon the plantations on the banks of the Wateree River, where I had medical charge of many hundreds of laborers and planters; the latter portion of this period has been spent in this city, residing during the summer months at Carmansville, and pursuing the practice of medicine in those so-called malarious suburbs, Washington Heights and Fort Washington, where I had under my medical charge three institutions, which contain about fifteen hundred children, teachers, and other employés. These conclusions have been confirmed by oral communications from experienced practitioners in this city, and are sustained, as will be shown, by ample statistical data.

From the days of Lancisi, malaria has been recognized as a peculiar influence existing in paludal localities, and emanating from the combined action of heat, moisture, and vegetable matter. This view, somewhat modified but not essentially altered, is to-day held by a large majority of medical men in all countries, but especially in tropical and semi-tropical regions, where malarial diseases are more frequently observed. Recently, however, a number of able gentlemen in the New England States and elsewhere in this country, claim to have discovered facts, which lead them to controvert the established opinion. A late convert¹ to the anti-Lancisian doctrine of the etiology of malarial fevers, writes: "Lancisi's investigations were extensive and searching and his conclusions seemed so irresistible that they were adopted by scientific men at once, and have since maintained, until within a very brief period, an assured place as truths in professional literature. Those who subsequently published medical works, which needed to include diseases of a miasmatic character, accepted without question or further investigation the opinions inherited, so to speak, from the learned author. Thus they passed from hand to hand, and finally reached our period, bearing such emblems of authority as to challenge and disarm criticism."

The history and literature of medicine do not sustain this author in the opinion that the men, great and small, who have written and lectured upon malarial diseases during the past one hundred and seventy-five years have "accepted without question or further investigation the opinion, so to speak, inherited from the learned Roman author."

The fact that two-thirds of the mortality of many thickly populated portions of the globe is due to malarial diseases has stimulated investigation to the utmost. The array of writings on this subject contained in the library of the Surgeon-General's office, U. S. Army, bears abundant testimony to the constant agitation of this subject during the past one hundred and seventy-five years. The last volume of the "Index Catalogue" devotes one hundred and forty closely printed columns to the enumeration of the titles of works on malarial diseases, the great majority of which have been published since Lancisi's

¹ New York Medical Record, August 18, 1883.

day. The Lancisian theory has, in fact, often been subjected to criticism. Dr. Wm. Fergusson in his paper "On the Nature and History of Marsh Poison" in the *Edinburgh Philosophical Transactions* endeavors to show that vegetation is not necessary to the development of malaria. Sir Gilbert Blanc offers similar arguments in his description of the Walcheren fever.

Deputy-Surgeon-General Munro¹ takes strong ground against the Lancisian doctrine, arguing in favor of "certain electrical conditions." Dr. Oldham's "chill theory" of the causation of malaria has also attracted much attention. The views of these writers were ably controverted by two papers,² by Dr. Maclean of Netley—which gave rise to an animated discussion in the *British Medical Journal*. These references will suffice to demonstrate that the Lancisian theory has not only *not remained unquestioned* but has been vigorously assailed. It would indeed be remarkable, were this not so. The theory and practice of medicine have passed through great changes during the past one hundred and fifty years; disease has been studied with more accuracy; new disorders have been recognized which were formerly regarded as symptoms only, and a complete revolution has taken place in therapeutics. But amid all this upheaval the Lancisian theory of the etiology of malarial fever stands unshaken, and is accepted by the larger majority of the profession in every part of the inhabited globe. To-day this theory is again assailed. Not in the malaria-ridden regions, not in India, Africa, South America, and the Southern United States, where malarial diseases have scourged the people from time immemorial, where their irrepressible malignancy has aroused the strongest efforts of government and people, but in the New England States, where their prevalence appears to be of recent date, is the iconoclastic hammer heard. Far be it from me to impugn the candor and ability of the authorities who have investigated these diseases in New England. I have been deeply interested in their writings and especially in following the recent trials of the Mill-dam question, in which the polemic talent of several gentlemen, supported by their scientific attainments, shone with brilliancy. As this question is the subject of the Fiske Fund (?) Prize Essay for 1884, I refrain from entering here upon its discussion and await anxiously the developments of the future.

In the meantime I would affirm that my own observations, made during the past quarter century, in the vicinity of Southern rivers, whose banks are frequently overflowed, and amid the swamps along their course, sustain me in the following points.

First.—A combination of solar heat (above 60° F.), moisture (below the saturating point), and vegetable matter (not living) is necessary for the production of *true malarial fevers*.

Second.—Any influence which withdraws one of these elements, renders the remaining incapable of generating true malaria. A "black frost," which term implies a temperature which completely destroys all vegetation not perennial, followed by a continuous temperature below 60° F. invariably checks malarial emanations. Fevers which have scourged plantations during the entire summer cease to furnish new victims after such a frost, and the planter often congratulates himself upon an accession to his working forces, while he deplores the loss of his "top crop" of cotton. I will cite only one illustration from my observation. The Wateree River, in South Carolina, is subject to frequent overflows, by which the alluvial lands on its borders are inundated. After the summer or August freshet numerous cases of malarial fevers invariably spring up among the laborers residing near the banks of the river; after the winter or February freshet, on the contrary, no new cases are observed, unless the temperature reaches 60° F. and re-

mains above this point for a considerable period. Again, perfect drainage, by withdrawing the element of moisture entirely, inhibits malarial emanations. This has been so often demonstrated that it has become an axiom in agricultural and sanitary engineering. Thoroughness is a *sine qua non* in this as in every other sanitary procedure. Partial drainage will, as Dr. Russell justly observes (*MEDICAL RECORD*, August 18, 1883, p. 179), be succeeded by a positive increase rather than by a subsidence of miasmatic troubles. The reason is obvious.

Third.—It has been long regarded as an established fact that malarial disorders prevail chiefly in rural or suburban localities. Hence the term swamp fever, paludal fever, country fever (used in the South). Experience has taught that the crowded cities of the temperate zone offer an uncongenial soil for their development, the diseases disappearing under the improved drainage and with increase of buildings upon sites which formerly furnished all the elements for the development of malaria.

Fourth.—Malarial fevers are very amenable to treatment in temperate climates. Ordinary remittent fevers have been very rarely fatal, in my experience; ordinary intermittent, of all types, have never proved fatal, within my recollection.

Impressed with these views by personal observation, by intercourse with physicians laboring in the same field, and by careful study of the literature pertaining to malarial diseases (these forming fifty per cent. of my aggregate of cases), I received with some surprise and not a little scepticism the information that malarial diseases prevail extensively in New York City, and that a large mortality is ascribed to them.

I have investigated this subject during the past three years, and now offer the result of my studies, not in the spirit of criticism, but prompted by a desire to direct attention to certain errors, which I hope to render clear to the unprejudiced reader.

I.—New York does not furnish the combination of elements necessary for the production of *true* malarial fevers, except to a limited extent, and in certain circumscribed localities.

In the summer of 1880 I asked the advice of medical and lay friends with reference to removing my family to that beautiful suburb, Washington Heights, for the summer. I was informed that this section of the city would prove an insalubrious summer resort; that, in fact, it is one of the most malaria-ridden parts of the island, on account of its proximity to the Harlem and Hudson Rivers.

Being attracted by the location of the "Heights," and feeling somewhat reassured by the fact that my family had become thoroughly inured to a malarial climate, I ventured to disregard the advice of friends, and took up my residence at Carmansville on June 18, 1880. I spent the entire summer in this beautiful suburban village, and became so impressed by its salubrity that I decided to again adopt it as a summer home. Having passed three summers at this place, I am convinced that it enjoys as much immunity from malarial diseases as any portion of the world not specially favored by altitude or remoteness from water-courses. The malarial cases which came under my observation were due to local causes acting in circumscribed localities, and removable by the most simple sanitary measures. Until the past summer I had not kept a record of malarial cases, but the idea impressed itself on my mind that genuine malarial fever was not often seen outside of the circumscribed localities to be presently mentioned. The fact is, that this portion of the island which stands in bad repute as a malarial section represents a rocky bluff, averaging one hundred and fifty-nine feet above the Hudson and Harlem Rivers.¹ On the eastern side it rises abruptly from the Harlem flats (which, by the way, furnish a perfect specimen of malaria-producing soil). But the bluff

¹ Remarks on Malarious Fevers and Cholera, Army Medical Department Report, 1872. London, 1874.

² British Medical Journal, 1874, vol. ii., 766 and 806.

¹ Measurements obtained from Matthew Cox, C.E.

is protected against malarial invasion from this side by a magnificent growth of trees, whose deep verdure not only graces the rocky promontory, but whose abundant foliage offers an effective barrier to effluvia arising from the flats. Four cases occurred during the past summer, in a house which stands on the extreme eastern point of One Hundred and Fiftieth Street, immediately overlooking the flats. An open vista to the latter is formed by the more sparse growth of foliage at this point. Another case occurred near the Aqueduct at One Hundred and Fifty-eighth Street, where a depression exists, which receives the garbage and filth from many wagons. A sixth case was seen on the brow of the slope at One Hundred and Ninetieth Street. These six cases are the only true malarial (intermittent quotidian) fever which I saw on the whole eastern border of the bluff from One Hundred and Forty-fifth Street to the upper point of the island. The remaining cases which I have noted during the past summer were observed in the following localities: Four on One Hundred and Fiftieth Street, and two on One Hundred and Fifty-first Street, between St. Nicholas and Tenth Avenues. These streets are partially occupied by buildings, all of which are wooden tenements. There is neither drain nor sewer, and filth accumulates in heaps until it reeks in the noonday sun. Here is every element for the production of malarial fever, which prevails every summer, and which may be effectually banished by draining and scavenging. One case was treated on One Hundred and Sixty-first Street, another on One Hundred and Sixty-second Street, between Tenth and Eleventh Avenues, near a point through which a blind sewer passes, but not a single, even superficial drain. Another case was seen on One Hundred and Sixty-third Street, near the Kingsbridge Road, in the midst of a market garden, which was cultivated near a basin where water could not readily drain away. At this point I observed two years ago the only cases of true remittent fever which I have seen since my departure from the South. One, a child, accompanied by convulsions in the cold stage, recovered; the other, a young girl, who was seen only a few hours before death, had been treated for malarial fever by a colleague. The last case of the season was observed on One Hundred and Forty-third Street, in a building standing on the edge of a stagnant pond, near Eighth Avenue. I may also mention two cases at the Colored Orphan Asylum.

All these cases occurred among the poorer classes, who occupy wooden tenements located in undrained localities. One case which was seen in a family residing in Audubon Park, near the bank of the Hudson, had contracted malarial fever during the previous summer at Hastings and had recently returned from a visit to Staten Island.

In the public institutions, which contained last summer over fifteen hundred inmates, I observed only two cases of true malarial fever, despite the fact that two of these, sheltering one thousand children and officers, are located in close proximity to points where some of the cases of malarial fever occurred. The small number of cases and the entire absence of fatality among so large a clientèle, afford unimpeachable testimony that malarial fevers are not endemic in this suburb, and that the prejudice existing in the minds of the people and the profession is unfounded. As an illustration of this prejudice I may cite the fact that an eminent surgeon of this city declined an invitation to send his child to Fort Washington (near the railway station) for recuperation, because he feared malaria. I have not seen one case of malaria within a considerable distance of this point during the past three summers. Several years ago another noted physician advised a family to remove to Washington Heights in order to restore to one of its members the health which had been shattered by malaria. Last spring a relative of this family sought an opinion from the same gentleman with reference to the

salubrity of Washington Heights and received an earnest injunction to leave it severely alone, "*because it is full of malaria.*" The truth is that no portion of this city or its suburbs offers such beautiful and healthful localities for residences, as does this garden spot of New York City. Elevated one hundred and fifty-nine feet above tide water, its rocky soil presents the most perfect foundation for buildings, and opportunity for draining with ample "fall." Its wide streets, St. Nicholas Avenue, Tenth Avenue, and Boulevard, Kingsbridge Road, 145th, 155th, and 175th Streets, will ere long be thronged by residences of people whose good sense will teach them the advantage of pure air within easy access of the busy marts of the metropolis. The sanitary authorities appear to be preparing for this event, by the construction of large sewers and drains, and by the filling up of the flats from 145th to 155th Street.

During the spring, fall, and winter months I have observed malarial cases only in a few localities, and chiefly in persons who traced the malarial infection to a period long antecedent to the attack.

That true malarial fevers do occur in this city cannot be denied. There are many localities which furnish all the elements for malarial emanations, as unoccupied lots, receiving surface drainage, and points where excavations are made for buildings or sewers. Here, however, the disease is found circumscribed by and traceable to the local causes.

It follows, from my *personal observation*, therefore, that there is no ground for the popular idea that New York City is a vast laboratory for the production of malaria.

11. The temperature of New York City in midwinter is not favorable for the development of true malarial fevers, especially of a serious type. If there is one point that has been recognized by practitioners in the Southern United States and in tropical countries, it is the fact that frosts and low temperature destroy "malaria," and check at once epidemics of diseases due to the latter. Referring to malaria, Bishop Heber in his "Narrative of a Journey through the Upper Provinces of India," relates that not monkeys only, but everything which has the breath of life instinctively deserts them (the woods) from the beginning of April to October.¹ "It is in the extreme heat, and immediately after the rains have ceased, in May, the latter end of August, and the early part of September, that it is most deadly. In October the animals return." "From the middle of November to March troops pass and repass, and with common precaution no risk is usually apprehended." "The period of the year during which malaria is most active is summer and fall, from June to November—for at this period only has the sun sufficient power" (Bartholow).²

"It is furthermore well known that the development of the disease usually takes place during the summer months, and that it disappears, or *at least no new cases arise during the winter unless the latter is mild.* We know, too, that the form, type, and intensity of the fever are usually in pretty direct relation to the temperature of the atmosphere. This is not only established by the testimony of writers from warm climates, etc." (Hertz).³

"In the more temperate and colder climates the winters are usually free from the disease" (Hertz).⁴

It would indeed be an act of supererogation to cite additional authorities in affirmation of the proposition that malarial diseases of serious types do not prevail in any city of the temperate zone during the winter. And yet the reports of the Board of Health of New York City (for which I am indebted to Dr. W. Delf. Day and to manuscript from Dr. John T. Nagle) furnish the following statistics which I have compiled from the records:

¹ Watson's Practice.

² Pract. Med., p. 775.

³ Ziemssen's Cyclopedia, vol. ii., 568.

⁴ Op. cit., vol. ii., 564.

AVERAGE TEMPERATURES AND DEATHS FROM MALARIAL FEVERS IN NEW YORK CITY FOR 1877, 1878, 1879, 1880, 1881, AND 1882.

PERIOD.	Average Temperature.	Number of Deaths.
January to April	33.98°	586
April to July	60.06°	684
July to October	72.37°	954
October to January	46.14°	812

With an average temperature barely above the freezing point we are expected to believe that New York furnishes 586 deaths in three years, or nearly one hundred deaths from malarial fevers in three months. This is a startling record, the comparison of which with the statistics of any other city of the temperate zone will demonstrate that a serious error is hidden within it.

In Dr. Chaille's¹ able statistical papers it is shown that the total mortality from malarial fevers in New Orleans from 1856 to 1860 was 1,315, and of this number 1,047 were reported from May to October (inclusive), and 268 from November to April (inclusive), affording evidence of the fact that even in semi-tropical New Orleans the winter mortality from malarial fever is as one to about four of summer mortality, *while in New York City the summer and winter mortality from the same diseases are nearly equal.*

III. The recorded fatality of malarial fevers in New York City adds another proof that the diagnosis of these diseases is inexact. Deaths from malarial fevers in New York from 1876 to 1878 were as follows:

Remittent fever	1,083
Intermittent fever	984
Typho-malarial fever	709
Congestive malignant intermittent fever,	79
Congestive chill	4

This table demonstrates that *the preponderance of mortality is not in cases of congestive and malignant fevers, but in the remittent and intermittent types.*

Is this large mortality in accordance with the accepted view of the prognosis of remittent and intermittent fevers?

"In the uncomplicated form of intermittent fever, without malignant tendency, the prognosis is almost always favorable. I have never seen such a case terminate fatally" (Wood).²

"The prognosis [of remittent fever] is generally favorable. The milder forms of the disease almost always end in recovery, unless mismanaged, and the severest often yield to prompt and suitable treatment, etc." (Wood).³

"In cold countries, such as ours, it [prognosis of intermittent fever] is almost always favorable. To persons of tolerable health and strength we may confidently promise a cure. Even the more strongly marked inflammatory form of the fever seldom terminates fatally" (Watson).

"The direct mortality from ague [syn. of intermittent fever], at all events among the European races, is small. Remittent fever is usually seen in its gravest forms in hot climates" (McLean).⁴

"Ordinary simple intermittent fever, as regards immediate danger, is not a grave affection. Whenever the disease involves immediate danger, it is to be considered pernicious and not, therefore, belonging to the head of ordinary or simple intermittent fever" (Flint).⁵ "Simple remittent fever in itself does not involve danger to life; as a rule, it is apt to be more severe in tropical than in temperate climates" (Flint).⁶ "The prognosis in simple intermittent fever is good" (Loomis).⁷ Death should rarely occur. Even cases of the severest types

of this fever should terminate in recovery—the type of the fever varies very much according to locality. The *remittent fever which we see in this city is of a mild type*" (Loomis¹), *italics mine.*

But why quote authorities on this subject? Every tyro in medicine knows that the prognosis of intermittent and remittent fevers of temperate climates is favorable, since the recognition of the specific anti-malarial properties of quinine. In the South a practitioner who would lose even a small proportion of his cases of intermittent and remittent fever would be forced to seek other fields, so seriously would his reputation suffer. Even the algid and pernicious fevers are no longer fatal if seen in the early stage, when the patient's system may be saturated with quinine.

If further proof is required to demonstrate that many physicians in this city diagnose malarial fever with extreme recklessness, it is furnished by the Report² of Dr. Charles P. Russell, Sanitary Inspector of the Board of Health. He says: "Two hundred and thirty-one deaths from malarial diseases were recorded within the year [1876]. All such cases were assigned to sanitary inspectors for investigation, with the main object of ascertaining definitely, if possible, the locations where said diseases had originated. In order to arrive at a satisfactory conclusion in any instance, the inspector was obliged to see personally, or communicate with the attending physicians, and frequently, also, to make an inspection of the place where the death had occurred. Many physicians refused or neglected to afford any information on the subject. *Quite a number of cases were excluded on account of uncertainty as to the actual cause of death, or as to its complication with a malarial element* [italics mine]. Ninety-six cases, however, were fully investigated."

Out of 238 cases, 142 were excluded on account of "uncertainty," or refusal and neglect of physicians to aid in establishing the correctness of their diagnosis! and out of the 96 cases fully investigated 10 are recorded as "malarial disease," a very obscure diagnostic designation of a fatal malady.

It follows, therefore, that only about one-third of the mortality ascribed to malarial fevers in New York city in 1876, may be indisputably attributed to the true forms of these fevers.

This result of a careful investigation by a gentleman who is an expert in sanitary inspection lends unimpeachable confirmation to the evidence above adduced, to establish the fact that the errors which are constantly committed in the diagnosis of malarial fevers have conferred upon New York a reputation as a malarial city which is as unenviable as it is unmerited.

158 WEST FIFTY-FOURTH STREET.

A LITHOPÆDION.—At a recent sitting of the Académie des Sciences, Dr. Sappey exhibited a foetus which had died at the end of six months' extra-uterine gestation, and had afterward been retained in the mother's abdomen for fifty-six years. The mother became pregnant at the age of twenty-eight, but labor did not come on at term nor afterward. At the age of eighty-four she went into the infirmary at Quimperlé, where she died three weeks after admission. At the necropsy a large hard cyst, with calcified walls, was discovered adjoining the uterus. This was divided by a saw, and found to contain a foetus in a state of almost perfect preservation. The skin, lungs, muscles, and other parts had preserved their normal softness and appearance. M. Sappey explains the preservation of the foetus by means of Pasteur's theory concerning the exclusion of air and aerial germs. It is a noteworthy fact, that these cases of lithopædions have been in the most authenticated instances of extra-uterine origin.

LICHEN RUBER OF HEBRA AND LICHEN PLANUS OF WILSON.

By A. R. ROBINSON, M.B., L.R.C.P. & S.,

PROFESSOR OF DERMATOLOGY IN THE NEW YORK POLYCLINIC; PROFESSOR OF HISTOLOGY IN THE WOMAN'S MEDICAL COLLEGE OF THE NEW YORK INFIRMARY; ATTENDING PHYSICIAN TO DEMILT DISPENSARY, SKIN DEPARTMENT, ETC.

(Continued from p. 429.)

Lichen planus.—This form of eruption was first described by Erasmus Wilson, and consists of papules remarkable for their color, shape, tendency to arrangement in groups, situation, local and chronic character, and the pigmentation they leave when they subside.

Color.—The color of the papule is a dull red, more or less vivid and suffused with a lilac tinge, which is most characteristic in recently formed and discrete papules; while in aggregated papules and in those of long standing it is of a dusky hue. A slight hyperæmic areola is present at the base of recent papules.

Shape.—When very small the papules are roundish in shape, but when fully developed they are generally angular in outline and rise abruptly from the normal skin. They range in size from one to three or four lines in diameter, are but slightly elevated above the general level of the skin, and have a flat, smooth, shining surface, which is frequently depressed in the centre—umbilicated. The papules are covered on their surface by a thin layer of horny, transparent cuticle, which is not a scale, and neither separates or exfoliates (Wilson). When the papule subsides this layer disappears without exfoliation. If the eruption is diffuse and aggregated there is some desquamation and scaling, especially if the part has been irritated, and appearances somewhat resembling a small diffuse patch of lichen ruber or of chronic, dry, scaly eczema or psoriasis. Upon the removal of the thick adherent scales in these cases the skin beneath may present an excoriated surface.

Arrangement of the papules.—The papules are either discrete or aggregated, but generally show a tendency to form larger or smaller groups. Occasionally they are arranged as broader or narrower, longer or shorter bands. In the discrete form of eruption the papules arise successively, and after a time variously sized patches are formed, consisting of aggregated and discrete papules united by an inflamed and infiltrated base. The inflammation and infiltration cause a blending of the papules and interpapular skin, and the formation of a raised, thickened, scaling patch. The eruption spreads peripherally by the formation of new papules at the same time that the older papules disappear, leaving behind a dark pigmentation. A single papule may spread by peripheral growth until it has reached, say, the size of a split pea; but a large patch is never formed by peripheral growth of a single papule, as occurs, for instance, in psoriasis. Sometimes a patch is large enough to show a raised border and depressed centre, or a ring is formed by the formation of a chain of papules at the periphery of a patch. If neighboring rings coalesce the eruption at that place will assume a gyrate form. A patch may consist of a depressed and pigmented centre; external to this large, well-developed papules, and a periphery formed of small developing papules.

Situation.—The eruption is generally symmetrical, and appears especially upon the anterior surface of the forearms, just above the wrists; it may, however, appear upon any other part of the body, and especially upon the lower part of the abdomen, the calves of the legs, and around the knee. It has been observed upon the palms of the hands and soles of the feet, upon the penis and on the mucous membrane of the mouth and fauces.

Course.—The course of the eruption is very chronic, and the individual papules may remain unchanged for many months before undergoing a retrograde process. When they disappear they leave behind deep pigmentation and occasionally a slight atrophy. When removed by treatment, it has been observed that old papules leave behind more pigmentation than recent ones. The erup-

tion never appears in the form of vesicles or pustules. The hairs and nails remain unaffected in this disease. There is generally very little itching attending the eruption, but sometimes it is intense. The general nutrition of the body is never affected; no matter how long the eruption lasts, it does not produce any of the grave conditions observed in lichen ruber, owing probably to its not becoming general over the whole body.

Histology.—The changes occurring in the skin in lichen planus have been studied by Neumann, Tolcott Fox, and Crocker.

According to Neumann (*Ibid.*, p. 310), the principal changes occur in the upper layers of the skin, the hair-follicles and sebaceous glands not being affected. He found the corneous and rete layers hypertrophied, the nucleus of the rete cells granular and swollen; the papillæ broader, conical in shape, and containing much granulation tissue; the papillary blood-vessels dilated, and their walls infiltrated with cells; the cell infiltration extending also in the form of bands around the blood-vessels and sweat-glands in the cutis. The unstriped muscles were hypertrophied. The orifices of the sweat-ducts were dilated from an increase in the number of epithelial cells; the sweat-duct was also dilated from the same cause, and on the gland itself numerous colloid degenerated cells were present. From these observations, Neumann concludes that lichen planus is a circumscribed inflammation of the upper part of the cutis and sweat apparatus, the latter being the primary seat of the disease. In judging of these conclusions of Neumann, it must be remembered that his description of lichen planus does not correspond in some respects with that which I have given, and which corresponds to the description of English and American writers. Neumann describes an increase in size of the papules to about an inch in diameter by growth of the periphery as a normal occurrence—a statement at variance with all other observers. This fact leaves us in doubt as to the value of his observations in lichen planus.

Talcott Fox (*British Medical Journal*, 1880, p. 398) thinks it should not be classed among the inflammatory affections of the skin, as he considers no true inflammatory action is present. According to him, the papules owe their origin to persistent neuro-paralytic hyperæmia and its results—namely, dilatation of the blood-vessels and engorgement of the tissues with blood, emigration of leucocytes, oedema, hypertrophy of the various structures, and slight desquamation. This view of the cause of the papule formation will be referred to after the structure of the papule is described.

Crocker (*Lancet*, 1881, p. 284), judging from his description of the eruption on the patients from whom he removed portions of skin, undoubtedly examined sections of lichen planus papules only, and not any of lichen ruber. As, however, he regards the two forms of papules as belonging to the same disease, he concluded that as his observations differed from those of Neumann and Biesiadecki on lichen ruber, the views of these observers were wrong, or else they had examined only papules of long standing. In quoting Crocker's views, therefore, it is to be remembered that he believes his description applies to both lichen ruber and lichen planus, although he had only examined sections of papules of lichen planus.

My own observations will be found to agree very closely with those of Dr. Crocker. In the more acute cases he finds the papule formed almost entirely by a cell effusion from one of the vessels of the superficial plexus pushing up the superimposed epidermis. This cell effusion is sharply limited at the sides, and involves several papillæ. The papillæ are flattened out, the rete is slightly hypertrophied, and there is some loosening of the upper layers of the horny cells over the centre of the papule.

In the more chronic forms, the papule is mostly formed from proliferation of the rete mucosum, the lower layers of the rete cells being flattened, and the upper layers, in-

cluding the stratum lucidum and granular layer, very distinct. The horny layers are only thickened over the centre of the papules. There is no change in the hair-follicles, unless it be that the orifices are funnel-shaped and packed with cells.

From the foregoing observations his conclusions are :

First.—The process at the commencement is entirely superficial.

Second.—That it consists of an inflammatory effusion from the superficial plexus of vessels, the cells from the horizontal vessels coming only from the upper surface.

Third.—That all the vessels of the plexus are notably dilated, and the papillæ are enlarged by downward growth of the interpapillary processes.

Fourth.—That all the epithelial layers undergo proliferation, the rete taking most part in the formation of the papule.

Fifth.—Involvement of the hair-follicles is not essential to the main process.

Sixth.—The sweat-ducts often have an influence in determining the situation of the papule and in producing the umbilication, as they were frequently present in the centre of the papules.

Through the kindness of Dr. Bronson and Dr. Morrow, of this city, I have been enabled to obtain both recent and old papules of lichen planus for microscopical examination. The papules were first hardened in Miller's liquid and afterward in alcohol, and sections examined both before and after staining with different agents. Microscopical examination of sections of a recent papule showed the following condition.

FIG. 3.—Complete Section of a Recent Papule of Lichen Planus under a Low Magnifying Power. The section includes normal skin at both sides, but most at left side : *a*, corneous layer ; *b*, rete mucosum ; *c*, orifice of sweat-duct ; *d*, round cell infiltration ; *e*, blood-vessel ; *f*, corium.

In Fig. 3 is represented a vertical section of a recent papule of lichen planus, together with normal skin at both sides. The papule corresponds to the region occupied by the dense round cell collection in the papillary region and upper part of the corium (*d*). The corneous layer in the region of the papule is almost entirely absent, consisting only of one or two layers of dried flat horny cells. The absence of the corneous layer in this situation was observed in all the sections of both recent and old papules examined, and consequently was not an artificial condition from cutting or manipulation of the sections. Outside the papule region the corneous layer is of normal appearance and thickness, as seen in Fig. 3, *a*. The rete mucosum is thickened in some places, especially in the central portion of the papule area. Papillæ are not recognizable in the central part of the papule. The papillæ and upper part of the corium are occupied by a sharply limited dense collection of round cells (*d*). At the periphery of this collection the blood-vessels are dilated and crowded with corpuscles, while a considerable number of emigrated white blood-corpuscles are present directly around the vessels. The deeper portion of the corium appears normal, except that some of the blood-vessels are dilated and surrounded by a few emigrated corpuscles. Examining such a section with higher powers, the rete is found to be hypertrophied in the central portion of the papule, and especially in the region of the sweat-ducts. The cells of all the layers over the dense round cell collection in the corium are flattened in a horizontal direc-

tion, the amount depending upon the amount of pressure from below, as shown by the almost normal condition of the cells toward the periphery of the papule. The granular layer is much thicker than usual, consisting sometimes of five or more layers of cells where the rete is thickest. This hypertrophy of the rete is very variable

FIG. 4.—Vertical Section of the Central Portion of a Recent Papule of Lichen Planus. *a*, orifice of sweat-duct ; *b*, round cell collection ; *c*, region of a blood-vessel.

as to situation and extent. Generally it is greatest in the centre of the papule and in the region of the sweat-duct orifices, but may occur in the latter situation only. In many places within the area of the papule there is no appreciable hypertrophy, and in the earliest stage of the eruption it is entirely absent.

The cutis papillæ in the central portions of the papule are so infiltrated with cells and the rete so flattened that in some cases the line of separation between the rete and cutis is not recognizable, as is the case in Figs. 3 and 4. If the cell collection is not very dense the papilla will be observed to contain dilated blood-vessels. At the outer portions of the papule the papillæ contain a more or less dense collection of round cells and dilated blood-vessels. The cell infiltration into the papillæ and upper part of the corium consists of embryonic corpuscles (white blood corpuscles), which take the place of the connective tissue to a greater or less extent. At the outer portions of the papule connective-tissue bundles are still present, but in the central part ; when the collection is very dense, all trace of connective tissue is lost. In the deeper parts of the corium there is nothing abnormal except the presence of a few dilated blood-vessels, some of which are surrounded by emigrated corpuscles.

The hair-follicles and sweat-glands are normal, except that around the sweat-ducts the cell infiltration generally extends deeper than in other parts. In all of the papules examined a sweat-duct was found near its centre, and seemed to be the principal cause of the umbilicated appearance of the papules, as its presence prevented the pushing upward of the epidermis by the round-cell collection. This umbilicated appearance was also partly owing to the absence of so much of the corneous layer from the central portion of the papule. The hair-follicles had no influence in determining the situation of the papules.

From the foregoing observations the papules of lichen planus examined by me owed their origin to an inflammatory process occurring in the papillæ and upper part of the corium, as shown by the round-cell infiltration and the changes in the tissues of the part. The cell infiltration from the horizontal plexus did not come from the upper surface of the vessels alone ; in fact, I know of no condition, nor can I imagine one, in which only one-half a capillary wall will undergo such nutritive changes as to permit of emigration of white blood corpuscles through it while the other half remains normal. The changes observed in the rete and corneous layer are

variable in amount and extent, and can be safely regarded as secondary conditions depending upon the changed nutrition condition in the cutis. If the papule is of long standing there may be considerable hypertrophy of the rete and corneous layer, as shown by the observations of Dr. Crocker, and further substantiated by the scaly appearance of some patches of the eruption. The dense cell infiltration, by its pressure upon the papillary blood-vessels and interference with their circulation and nutrition, allows of the passing out of red blood-corpuscles, as occurs in the dense cell infiltration in connection with syphilitic papules. As a result of this extravasation we have the dark red color, and the pigmentation remaining after disappearance of the papules. In the return to the normal condition the changes are such as usually occur in inflammatory states, the round-cell collection disappears by fatty degeneration of the corpuscles and the epidermis regains its normal activity. I have not had the opportunity of examining skin where a papule had previously existed, but I have seen the fatty degeneration of the round cells.

According to the above description, lichen planus papules are the result of a circumscribed inflammation of the papillæ and upper part of the corium, and any changes in the epidermis are secondary to the changed nutrition, the result of this localized inflammation.

Prognosis.—The prognosis is always favorable, the disease having a tendency to spontaneous recovery after weeks or months of existence, and never leads to the low marasmic condition observed in untreated cases of lichen ruber.

Treatment.—In many of the subjects of lichen planus the general nutrition of the body is below a normal physiological standard, and tonics with appropriate diet are indicated. In other cases the eruption seems to be the only pathological condition present. Alkalies, especially the acetate or citrate of potash with tonics have been found to be of service in some cases. In one case reported by Dr. R. W. Taylor (*Archiv. of Derm.*, 1874) immediate benefit followed the administration of twenty grains of chlorate of potash dissolved in four ounces of water, given fifteen minutes after meals, and followed fifteen minutes later by twenty drops of dilute nitric acid in a wineglassful of water. Arsenic does not seem to have any special effect in this form of eruption. Locally the itching can be treated in the same manner as the same condition in lichen ruber, or in other skin diseases. Beyond preventing itching, local applications do not seem to influence the eruption.

Relationship between lichen ruber and lichen planus.—From a comparison of the symptoms, histology, prognosis, and treatment of the two forms of eruption, as given above, we find that, as regards the symptoms; in lichen ruber the papules generally commence on the trunk and tend to extend over the entire body, and in lichen planus they generally commence on the forearms and legs, and very rarely spread over a large area. In lichen ruber the papules are round, acuminated, covered with thin scales, and only show a depressed centre when situated around a hair-follicle or undergoing a retrograde process; in lichen planus the papules are of irregular outline, generally umbilicated, and never scaly at the commencement. In lichen ruber the eruption is not symmetrical, and the papules do not increase in size by growth at the periphery; in lichen planus the eruption is generally symmetrical, and many of the papules increase in size to a certain extent by spreading peripherically. Lichen ruber, if not treated, leads to marasmus and death; lichen planus has no special effect upon the general condition of the system.

Hence, as regards the symptoms, course, and prognosis of the two forms of eruption, they are widely different from each other.

Histology.—From microscopical observation we find that lichen ruber is an atypical keratosis, and lichen

planus an inflammatory affection of the papillæ and upper portion of the corium, with subsequent changes in the epidermis. In lichen ruber the corneous layer is hypertrophied, the rete also slightly thickened, whilst there are few or no changes in the cutis; in lichen planus the corneous layer is often absent, the rete is thickened, and there is a dense round-cell collection in the papillæ and upper part of the corium. Lichen ruber is, therefore, an anomaly of growth of the corneous layer, and lichen planus an inflammatory affection of the vascular portion of the skin. As regards the pathological histology they are thus widely different.

As regards the treatment, we find that arsenic, which may be regarded as a specific for lichen ruber, has little or no effect on the eruption of lichen planus, and alkalies and tonics, which are frequently of much service in the latter, are of no benefit in the former.

The symptoms, course, histology, and treatment are therefore entirely different, and the question arises as to whether eruptions with such differences in these respects can still represent two forms of the same disease. The polymorphous eruptions of the skin are *par excellence* syphilis and eczema, and with reference to the former a macular syphilide bears no resemblance either in symptoms or treatment to a gummatous tumor, although both are but different forms of the same disease. A study of the natural history of syphilis teaches, however, that the macular eruption corresponds to an early stage, and the gummatous formation to a late stage of the syphilitic infection, and that both are an invariable sequelæ of the syphilitic poison; in other words, a study of these two forms of syphilis in any given case will show that both are but forms of the same disease. In eczema the eruption may be papular, vesicular, pustular, or squamous in character; but generally there is a combination of these different forms, and all can be regarded as a superficial catarrhal inflammation of the skin, the intensity of the inflammation or chronicity of the process accounting for the difference in the appearances presented. In the case of lichen ruber and lichen planus, the latter has been regarded as a mild form of the former, the difference in character being attributed to the climate and mode of living in England and America, where lichen planus is frequently met with, as compared with Germany, where lichen ruber is more frequent. It is true that these conditions as regards climate and mode of living do have an influence upon certain skin-diseases, although not to the extent generally believed. Those who have seen lupus vulgaris in Vienna and in America have observed the milder character of the disease in this country, depending probably upon the better diet of the laboring classes here as compared with that of Germany, but the difference is only one of degree; the situation, symptoms to a great extent, the pathological histology and treatment are the same, and even some of the cases observed here are as severe as any observed in other countries. In lichen ruber and lichen planus we have found that it cannot be a question of intensity of the pathological process, as the histology of the two forms of eruption is entirely different. Neither can they represent stages of the same disease, as no one has yet observed a case of lichen ruber develop into one of lichen planus, or *vice versa*. Here in New York a very considerable number of cases of lichen planus have been observed by the different members of the New York Dermatological Society, and although every member is conversant with the characters of the eruption in both lichen ruber and lichen planus, and consequently would be quick to recognize any transition from the one to the other, no case has been observed or reported in which this has occurred. The papules of lichen planus never change to those of lichen ruber, and *vice versa*; and no similarity has been shown to exist between the two forms of eruption, except that of slight resemblance in color and the papular form of the eruption. From a consideration of all the above observations, we feel justified in con-

cluding that lichen ruber and lichen planus are two entirely distinct diseases of the skin, and that the grounds for regarding them as but two forms of the same disease are altogether untenable.

356 WEST FORTY-SECOND STREET.

OXYGEN AND SOME OF ITS COMPOUNDS AS THERAPEUTIC AGENTS.¹

By SAMUEL S. WALLIAN, A.M., M.D.,

BLOOMINGDALE, N. Y.

(Continued from p. 457.)

It is an every-day fact in chemistry that substances identical in ultimate composition, as far as our yet imperfect art can discover, are strikingly different in a physiologic or therapeutic sense. Whether this difference consists in varying modes of atomic and molecular arrangement, or in different, but as yet indistinguishable, states of the oxygen base, is yet beyond our scientific ken.

Hence it does not follow that oxygen as found in common air, and the same element in doubtless a nascent and hyper-active state, as artificially generated—liberated would be a more accurate term—are either physiologically or therapeutically identical.

Again, the *physiological* relations of oxygen are definite and limited, while its *nature and potency as a therapeutic agent is, as yet, not generally understood, is entirely unlimited and as different from the former as though it were in reality another element.*

While all physio-chemists assert that it is an active eliminator, depurent, disintegrant, solvent, and perhaps, sorbent, and alterative, very few have taken the pains to investigate it in the light of a *materia alimentaria*, and hence a direct invigorator and renewer of the whole vital organism. Nor do we yet practically realize the evidently demonstrable fact that *there is no antiseptic known of equal potency with pure oxygen*; or that there is no known antiseptic compound which does not contain this vital element. It may yet transpire that all antiseptics depend for their special properties, directly or indirectly, on the free or feebly combined oxygen they contain. Should this presumption prove to be well founded it devolves on this micro-chemic age to devise methods for the convenient and successful use of the real and safe factor, to the exclusion of the noxious carbonized elements at present so largely composing antiseptic mixtures, and thus forever do away with carbolic, salicylic, and all other "antiseptic" septæmia!

Thus, Pasteur has demonstrated that by cultivating the disease-germ of chicken cholera for several generations in fluids having free access to the oxygen of the air it is gradually robbed of its virulence and eventually becomes inert; and Buchner succeeded in transforming the dreaded *bacillus anthracis* into the harmless *bacillus subtilis*—the hay bacillus—and *vice versa*, by repeated cultures in fluids freely supplied with oxygen or wholly deprived of the same, according to the results desired.

Prof. Law's² experiments with the virus of hog cholera fully confirm the foregoing results. The virus attains its maximum of virulence after cultivation in fluids occluded from free contact with the oxygen of the air, and is gradually, but surely, robbed of all malignancy by culture in fluids freely supplied with that element.

The same principle holds with regard to the propagation of yellow fever, typhoid fever, Asiatic cholera, diphtheria, croup, and the pleuro-pneumonia or lung-plague of cattle.

Another idea, not quite foreign to the subject, suggests itself: Has any chemical or physiological investigator queried whether the fundamental difference in the toxic tendencies of the two anæsthetics, ether and chlor-

oform, is to be found by a comparison of their chemical composition? CHCl_3 = chloroform; $\text{C}_4\text{H}_{10}\text{O}$ = sulphuric ether. In the latter one equivalent of oxygen does duty, while in the former none of the elementary constituents would sustain animal life for a moment.

The question of ventilation in crowded cities, public buildings, and even in private dwellings, will eventually resolve itself into improved methods for supplying and distributing, in suitable quantities, artificial oxygen, and *if the bacillus tuberculosis prove to be a veritable entity—the essential factor in the induction and propagation of phthisis—then must we find in pure oxygen, by one mode or another of administration, its one efficient germicide and antidote!*

If Koch be right, then is mountain air and the air of new countries, in phthisis, but a removal from germ-fostering to germ-discouraging atmospheres. And whether he be right or wrong, bad air is the culture-fluid of all zymotic and germ-engendered diseases the world over.

The field of profitable investigation suggested is fairly exhaustless, but space forbids its further exploration in this connection.

Recurring to the practical side of the subject, I have personally used oxygen in only its simple gaseous form, and exclusively by inhalation. As to proportions and combinations, I have exhibited the gas, first, pure or undiluted; second, diluted with common air; and, third, admixed with nitrogen monoxide in various proportions.

In asphyxia from drowning or the inhalation of noxious gases, in threatened fatal syncope, suspended animation, and some other emergencies, as uræmic coma, chloroform or ether narcosis, opium-poisoning, etc., the first form of administration is indicated. For general use in chronic diseases the undiluted gas is seldom appropriate; but is to be modified by proper dilution, or associated with nitrogen monoxide in various proportions, according to the exigencies of each case.

The various methods of exhibition of this agent may be briefly adverted to:

1. *Direct inhalation* will probably always stand at the head of all methods.
2. *Cutaneous absorption* has been resorted to in Europe, and may be found advantageous in certain cases.
3. *Oxygenated water* is a feasible and pleasant medium for stomachal administration. It is prepared by saturating steam with the gas, at high pressure, and afterward condensing the steam.
4. *Oxygenated bread* has been used to some extent in England, and there is no reason why the "aërated bread" of our cities should not be easily transformed into oxygenated bread at will.

Of this bread Dr. Birch (*op. cit.*, p. 18 *et seq.*) says: "Its relative effect on the appetite is singular. Thus on the one hand (as might be expected) it stimulates the appetite when absent or capricious, while, on the other hand, it tends to produce such a feeling of epigastric fulness, when sufficient food has been taken, as to effectually suspend (if not satisfy) some morbidly craving appetites. . . .

"In some cases it will be found advantageously to supersede artificial pepsin, pancreatin, and even quinine and the mineral acids. . . . It is particularly indicated in cases of delicate children with continually recurring ascariæ, functional derangement of the stomach and bowels, and mesenteric weakness."

In the matter of proportions and combinations, and as respects the quantity to be exhibited in a given case, there is as wide latitude for the exercise of professional discretion as in the compounding and selection of ordinary drugs.

That the use of oxygen in medical practice requires considerable time and care in its manipulation, and the exercise of much judgment and discrimination in its exhibition, and that impatient, over-sanguine, or careless practitioners will fail of satisfactory results in attempting it, is very true; but it may be made to add so largely to

¹ Read before the Franklin County (N. Y.) Medical Society, June 5, 1883.

² "Malignancy of Disease Germs Mitigated by Oxygen," THE MEDICAL RECORD, vol. xix., p. 673.

our therapeutic resources, is a desideratum in so many contingencies, and *the necessity for it increases so exactly in proportion to the increase of artificialness in the social and physical habits of modern society*, that the conscientious and painstaking physician of the future will undoubtedly avail himself of its aid in all appropriate conditions and emergencies.

The following cases are selected as representing the range of adaptability rather than any special features of the treatment. It will be noted in all of them that prompt and permanent aid to digestion and assimilation is a decidedly prominent if not the principal result.

CASE I.—Mrs. J. S.—, aged thirty-nine, married, two children, the youngest several years old. By profession a singer and teacher of music. Family history includes phthisis, of which she lives in great fear. Each winter has severe bronchial and laryngeal troubles, with persistent cough. Anæmic, extremities habitually cold; pulse, 102 to 108; constant subclavicular pain; dyspnoea and fatigue on slight exertion; weak digestion with bowels habitually constipated. She expectorates rather copiously; sputa muco-purulent; and there is circumscribed dulness over the apex of the left lung. She is very despondent, and has no faith that any treatment will avail.

March 25th.—She presents for treatment and is placed on daily inhalations for thirty minutes at a sitting—R. Oxygen, 25 volumes; nitrogen monoxide, 50 volumes; common air, 25 volumes. At a forced effort she can inspire 150 cubic inches of the mixture.

April 10th.—Improvement has been manifest from the first. The nitrogen monoxide acts as a wonderful calmative to the nervous system. She is no longer despondent; appetite much improved, coughs less, sputa reduced in quantity and less purulent. *Constipation effectually relieved.* Lung capacity, 190 cubic inches.

April 25th.—Resumed her music classes soon after last record. Improvement has been rapid and constant. Says she is "better than for many years;" eats, works, and sings with gusto. Considers herself "well," and treatment suspended.

(Observed this patient eight months later, no untoward symptoms reappearing.)

CASE II.—Mrs. C. L. W.—, aged twenty-nine, married, one child aged five. Family history says father died of cancer of stomach; mother of cardiac disease. She has "weak lungs," and lives in perpetual dread of "consumption." Sense of constriction in left lung; circumscribed "sore spot" under the left clavicle; severe cough for several years past, and there is now some dulness on percussion over the left apex. Has been treated by eminent physicians without appreciable benefit; very anæmic; voice weak; no appetite; amenorrhœic for three years past; menstrual discharge, when present at all, is either profuse, acrid, and colorless, or greenish in color, scanty, and offensive. Has been subject to repeated attacks of severe nephralgia. Urine not examined.

May 23d.—This patient was placed on a mixture of—R. Oxygen, nitrogen monoxide, $\bar{a}\bar{a}$ 2 volumes; common air, 1 volume, of which she inhales, twice daily, three gallons at a sitting. Shows a lung capacity of 130 cubic inches.

June 1st.—Improvement already manifest. Feels "rested;" eats better; says the "soreness" has nearly left her. Can now inspire 165 cubic inches at an effort. Treatment continued twice daily.

June 15th.—Acute nephritis suddenly developed, or at least the chronic condition of those organs assumes a subacute form. Temperature, 102°; pulse, 122. Urine scanty, specific gravity 1.030; some albumen and casts. Oxygen suspended and hot hip-baths ordered, with demulcent drinks, to be followed by hot fomentations over the region of the kidneys.

June 25th.—The acute symptoms, which were somewhat alarming at last record, soon subsided, and general improvement is very evident. Lung capacity, 200 cubic inches. Oxygen was resumed 20th.

July 1st.—Improvement continues. Menses appear naturally and without unusual disturbance. Appetite excellent; walks two miles a day without fatigue, sleeps well, and gains flesh rapidly.

July 10th.—Patient continues to improve. Treatment reduced one-half and conjoined with chalybeates. Lung capacity increased to 225 cubic inches.

July 25th.—Treatment suspended. Patient returns to her friends very much rejoiced at her progress.

(Two years later this patient reported no return of former symptoms.)

CASE III.—Miss A. B.—, nineteen years of age. Family history good, except that mother died young. Father, Judge —, quite robust at sixty-eight. She has suffered from spasmodic asthma since childhood, the paroxysms occurring daily and on the slightest exposure. She is very delicate, anæmic, and fatigued on slight exertion. Has constant dyspnoea and marked cyanotic appearance. Appetite weak and capricious.

May 25th.—Placed patient on—R. Oxygen, 1 volume; nitrogen monoxide, 4 volumes, of which she inhales five gallons, once daily, with the result of immediately relieving the dyspnoea. Her lung capacity is but 75 cubic inches.

June 4th.—Improvement has been steady. No more cyanosis; does not suffer from paroxysms; appetite fairly good. She inflates her lungs much better than at first; capacity, 100 cubic inches.

June 20th.—Proportion of oxygen increased to forty per cent. No return of paroxysms. General health greatly improved.

July 1st.—General improvement continues. From being caught in a storm has had one mild asthmatic paroxysm.

July 10th.—Patient can now endure active exercise without fatigue. Treatment continued every other day. Inspires 140 cubic inches.

July 25th.—Treatment has been irregular since last record, but patient's general health continues to improve; breathes, sleeps, and eats well. Exposes herself to changes of weather and temperature with impunity.

August 10th.—There has been no recurrence of the asthma, although patient asserts that she has repeatedly exposed herself to the same influences which invariably induced paroxysms previous to treatment. She is advised to continue the treatment at intervals, but as the family are about to remove from the city no further observations are practicable.

(November 30th.—This patient writes that she continues to enjoy excellent health, and has had but one asthmatic paroxysm since leaving the city—this from being drenched to the skin in a sudden rain-storm.)

CASE IV.—Miss E. L. C.—, sixteen years of age. For three years past subject to epileptic convulsions. Family history shows the malady to be hereditary. Patient tall, slender, with stooping, awkward gait, languid attitude, flabby muscles, sallow complexion, feeble pulse, morbid appetite, and poor digestion. Complains of constant cephalalgia, and, in short is decidedly chlorotic. Has never menstruated, and her mother associates her malady with this fact.

August 13th.—Patient placed on—R. Oxygen, 1 volume; atmospheric air, 2 volumes; four gallons at each daily sitting. Inhales but 60 cubic inches at an inspiration.

August 20th.—Mother reports that she sleeps better and does not have her nightly "fit." Can inspire 90 cubic inches at an effort. Ordered chalybeates and nutritious diet, for the latter of which she begins to show a natural desire.

August 30th.—Still no return of the paroxysms. Cephalalgia has disappeared; appetite, digestion, and general health much improved. Lung capacity, 100 cubic inches.

September 14th.—Proportion of free oxygen increased to fifty per cent; five gallons each sitting every other

day. Patient resumes her classes in school, walking several miles daily without fatigue. Inspires 105 cubic inches.

October 10th.—Slight convulsion after severe exposure, attending an evening political demonstration. Daily treatment resumed; same formula as at last record. Lung capacity increased to 115 cubic inches.

November 1st.—Improvement has been constant; appetite fairly insatiable; digestion excellent, and is one of the most boisterous of her class on the playground.

November 10th.—Treatment continued every other day. Catamenia appear, naturally and without disturbance.

November 25th.—Patient decidedly robust, and apparently, as she asserts herself, "perfectly well." Treatment suspended.

(Six months later there had been no return of the epilepsy; general health of the patient continuing excellent.)

CASE V.—A. S.—, aged fifty-one, married, several grown-up children; occupation, commission merchant. Has been twenty years an invalid; a confirmed dyspeptic, and suffers from constant and extreme nervous irritability and prostration (neurasthenia?). Constant frontal headache and frequently recurring paroxysms of a dull, benumbing pain referred to the medulla and base of the brain. Appetite wanting; constipation habitual, alternating occasionally with diarrhoea; extremities cold, is very despondent, and has suffered for years from a masked or "dumb" ague. Liver and spleen somewhat enlarged; urine turbid, specific gravity 1.030, abounds in alkaline phosphates, but deficient in urea and uric acid.

September 20th.—Daily treatment instituted, using—R. Oxygen, nitrogen monoxide, aa four gallons at each sitting. Lung capacity, 160 cubic inches.

September 29th.—The evidence of retention of urea in the system corroborated, and the value of oxygen as an eliminator well illustrated. Crowding the treatment from day to day, patient last night inhaled eight gallons of the mixed gases. Urine now loaded with urea; specific gravity, 1.035. Treatment continued, the dosage diminished.

October 11th.—The disturbances noted after first week of treatment have nearly subsided. Urine nearly normal as to quantity, but still shows excess of urea; specific gravity, 1.028.

Mixture changed to—R. Oxygen, 1 volume; nitrogen monoxide, 2 volumes; eight gallons at each daily sitting. Lung capacity increased to 200 cubic inches. Patient is less irritable, sleeps better, and feels greatly encouraged.

October 18th.—Improvement has been gradual but constant since last record. Cephalalgia is becoming a much less frequent symptom, and when present is less severe. Specific gravity of urine, 1.025.

November 11th.—Has steadily improved since last record, in spite of the drawback of constant business worry and overwork. Urine normal; lung capacity, 220 cubic inches.

November 20th.—Digestion good; sleeps well; no longer despondent or irritable; no headache; extremities in a comfortable glow; all his functions well performed. Treatment discontinued.

(Four months later this patient reported himself in active business and feeling strong and well.)

A PLEA FOR A HOMŒOPATHIC TEST.—The sum of \$25,000 has been offered to St. George's Hospital on condition that the money be devoted to a fair trial of homœopathy in the wards of that institution. The offer has been declined, at which the *Lancet* expresses great satisfaction. The only good reason for declining is that it has been often submitted to a fair test before, and unnecessary repetitions are dangerous.

TWO CASES OF CHOLO-CYSTOTOMY, WITH RECOVERY.

By MARTIN BURKE, M.D.,

NEW YORK.

THE cases of successful incision of the gall-bladder are not, I believe, so numerous that the report of two cases would be without interest.

James W—, eighteen years of age, came to my office in the month of October, 1881. He entered almost crouchingly, and said he had a severe pain in his belly whenever he stood erect. I examined his abdomen, and found that almost under but to the right of the ensiform cartilage there was a small fluctuating tumor, painful upon pressure, and of the size of a duck's egg. The boy was jaundiced, but not markedly so, and his bowels appeared to move, although constipation had immediately preceded this attack of pain. His fever—and he had some fever—was not pronounced. The abdomen, save where the tumor existed, was free from pain upon pressure, and I diagnosed an abscess of either liver or gall-bladder. The boy's pulse, however, being strong, I felt inclined to think it was a suppurating gall-bladder, and this afterward was found to be the case. I ordered the boy home, told him to go to bed, to poultice the tumor, and prescribed quinine and opium. As I was leaving town the next day, I directed my friend, Dr. Kearny, to see the boy and to do what his judgment dictated. He agreed with my diagnosis and resolved to cut immediately, which he did during my absence, and reported that a large quantity of bile and pus came from the incision. About a week after this, I was astonished one morning to see the boy come into my office, and upon examining the fistula left by the knife, I found I could pass in a probe for about three inches, but as it then commenced to bleed I desisted. I saw the boy once again after this, and his fistula was entirely healed.

Mrs. K—, aged fifty, was seized about a year and a half ago with a violent pain in the right hypochondriac region. The pain was severe, and this region was terribly sensitive to the touch, but rest, opium, and poultices relieved the pain until it was bearable. Yet sensitiveness upon pressure was marked, and this continued until blistering and leeching had been tried repeatedly.

At length, indeed, Mrs. K— was convalescing, but her health was not entirely restored. In May, 1883, she was taken with a similar attack, when I was again asked to see her.

This time leeching, blistering, and poulticing failed to reduce the sensitive spot, and indeed it appeared slowly to enlarge its limits and to become more painful. Continued applications of cantharidal collodion and poulticing were now regularly applied, and my father and myself resolved to open this enlarged and tender spot when we thought it safe to do so. Accordingly about eight weeks after the beginning of the second attack we opened an abscess from which were discharged fifty gallstones, whose combined weight was one hundred and thirty grains. The poulticing was continued, and the wound washed out thoroughly every six hours. Our patient had some fever following the operation, but none to occasion alarm. A drainage-tube was kept in for three days only, when I removed it. I may remark that after about a week of continued convalescence the patient lost all appetite; this was restored by the use of the wine of Mariani, which I believe contains coca.

Henceforward all went well, and Mrs. K— is now entirely well. At no time was she jaundiced. At no time did she lose courage, and her abiding faith in her medical attendants during the long, weary course of her illness made her case entirely free from the usual small anxieties which attend such cases. Such, then, are these two histories. One in a young male, one in a middle-aged woman. Severe pain noticed in both. In neither did a distinct chill occur, although in both pus occurred in large amount. In neither case was

jaundice noticed to any extent. The first case had a good history. In Mrs. K—— a rheumatic diathesis existed.

As regards differential diagnosis between abscess of liver and abscess of gall-bladder, I find the following characteristics. In this climate abscess of the liver follows, I think, either typhus fever or exhaustion consequent upon prolonged hard drinking. The tenderness in abscess of the liver is much further from the median line in the hypochondriac space than is the case in abscess of the gall-bladder. A prolonged chill or chills, very marked, usher in abscess of the liver; this was not the case in these two examples of the other disease. The constitutional disturbance is more marked in liver trouble. In both cases I should advise early incisions. I have the records of three cases of liver abscess, all fatal, in two of which I was so strongly advised by the consultant to aspirate that I did so, and delaying free incision until some days after, had occasion to regret it most bitterly.

Progress of Medical Science.

OTORRHOEA, WITH PERFORATION OF THE MEMBRANA TYMPANI.—Dr. Read J. McKay, of Wilmington, Del., having treated, during the past eleven years, two hundred and thirty cases of otorrhœa, or, more technically, chronic otitis media with purulent discharge, presents for consideration in *The American Journal of the Medical Sciences* for October, 1883, some clinical observations upon such cases with old perforations of the membrana tympani, and endeavors to show that they are not the unsatisfactory and irremediable class of aural diseases which they have been regarded, and perhaps still are, by many general practitioners as well as by the public generally. And because of the well-known dangers from caries and necrosis of the temporal bones, meningitis, cerebral abscess, and purulent infection, which sooner or later may, and often do ensue, when they are disregarded or neglected, they should not in the future, as in the past, be permitted by physicians to pass from under their observation without any, or carelessly directed, local and medical treatment. His earlier cases were treated by various caustic applications, and they required usually several months' treatment to relieve or cure them. The later ones were treated with finely powdered boracic acid (the dry method), packed in the ears, usually filling the meati the first few visits, which generally checked the purulent discharge in a few days and only required several weeks (usually about four) to relieve or cure them.

† EXPERIMENTS IN THE USE OF NAPHTHOL FOR THE TREATMENT OF SKIN DISEASES.—Dr. Arthur Van Harlingen, of Philadelphia, reports in *The American Journal of the Medical Sciences* for October, 1883, the results of his experience with the use of this drug, which was first brought to the notice of the profession by Professor Kaposi, of Vienna, about two years ago. He finds it is one of the most efficient and agreeable remedies for *scabies* which has as yet been brought forward. Both in the rapidity of its action and in its beneficial effects upon the inflamed skin it is superior to any of the means ordinarily employed for the cure of this disease. Its exact place in dermatic therapeutics remains to be ascertained, but he is inclined to think that it will not prove an unimportant one. In eczema it has failed in his hands to give the same beneficial results as were obtained by Kaposi. In most cases of vesicular and in acute eczema generally its action is simply that of an irritant. On the other hand, it has a limited field of action in the cure of a certain number of cases of squamous eczema of the scalp. In his opinion it is a valuable addition to our external means of treatment in *psoriasis*. Kaposi speaks well of it in *psoriasis* of the scalp in particular, and his experience would lead him to place it near chrysarobin and pyrogal-

lic acid in effectiveness without the neutralizing disadvantages of either of these drugs. In *seborrhœa* of the scalp naphthol is a decided addition to our means of treatment. While inferior in some respects to sulphur or carbolic acid, it has a certain range of usefulness which further experience will in all probability more exactly demonstrate. Naphthol is highly lauded by Kaposi in the treatment of *hyperidrosis*, but in Dr. Van Harlingen's hands it has failed entirely, although used strictly according to his formulae. He considers it quite valueless in this disease, so far as his experience goes, which leads him to regard its effects in *ringworm* as inferior to almost all of the remedies at present used, and as almost entirely inefficient in most cases of *tinea versicolor*. In *pediculosis* he has had no experience, but in a single case of *pediculosis capitis* its action was favorable.

CARBOLIZED SAWDUST AS AN ANTISEPTIC DRESSING.—Mr. H. P. Symonds speaks favorably of this material in *The Lancet* of September 22, 1883. He soaks a quantity of coarse sawdust in a ten per cent. solution of carbolic acid in spirits of wine, and then allows it to dry slightly, so that the spirit may evaporate, leaving the sawdust charged with carbolic acid. When used, it is enclosed in a bag made of several layers of gauze, and applied outside the deep dressing, the usual external dressings being put over it. The sawdust thus takes the place of the padding of gauze which is generally used. The advantages claimed for it are its powerful antiseptic qualities when saturated with carbolic acid, its great absorbent power, and its adaptability to any surface. The writer says that the sawdust should be coarse, as he has found that if it is very fine it passes through the gauze and irritates the skin.

THE ANTAGONISM OF PARALDEHYDE TO STRYCHNIA.—Professor Cervello has recently published an interesting paper in *Archivio per le Scienze mediche*, vol. ii., No. 1, on the antagonistic action of paraldehyde and strychnia. The experiments which led him to regard the two drugs as antagonistic were made in several ways: by administering a large but not fatal dose of paraldehyde, and then a dose of strychnine; by administering fatal doses of strychnine, and then a dose of paraldehyde; and finally, by administering the two drugs at the same time. As a kind of control experiment, the animals were then given doses of one or the other of these agents alone, so that the experimenter could judge of the narcotic effect of the paraldehyde, and of the fatality of the strychnine. In whatever manner administered, it was made clear that paraldehyde antagonized the action of strychnia; nor was it necessary to administer more than a physiological dose of paraldehyde in order to observe this antagonistic effect. Indeed, so small a dose of the narcotic was sufficient as not to produce its physiological effects. Two and a half grammes of paraldehyde completely antagonized four milligrammes of nitrate of strychnia administered to a rabbit, a dose four times greater than that necessary to kill. Curiously enough, the administration of strychnia had no influence on paraldehyde narcosis. Its duration was the same, whether the narcotic was administered alone, or both drugs together; in fact, the narcosis lasted longer in the strychnized animal. The retardation of the respiratory movements is the same, and we may say that the phenomena of paraldehyde always predominate, as if it had been given alone. The antagonism, then, is not reciprocal. This antagonism seems, therefore, to be central: paraldehyde depressing, and strychnia exciting the reflex irritability of the cord.

VARIATIONS OF THE URINARY CHLORIDES.—No one will deny that a more frequent examination of the constituents of the urine might lead to the acquisition of fresh knowledge. Even in our public clinical institutions the systematic estimation of the most important urinary constituents is not regularly carried out. A com-

plete clinical account of the changes in the urine which accompany the active stages of the rachitic process would probably be attended with important additions to medical science. Indeed, the same may be said of most acute diseases. In ordinary medical attainments perhaps the only piece of information with regard to the chlorides of the urine consists in the knowledge of the fact that there is a remarkable diminution of this ingredient in acute pneumonia. M. Burot has done well to draw attention to this unploughed field of clinical medicine. He has devised a simple apparatus for the purpose of estimating the chlorides. A small flask is furnished at its inferior extremity with an ampulla capable of holding just one cubic centimeter of urine. A pipette is obtained, gauged in tenths of a cubic centimetre. Another little flask containing a solution of argentic nitrate is used, from which the pipette may suck up some of its contents by means of a ball of caoutchouc. A cubic centimetre of urine is first treated with a solution of potassic chromate. The solution of nitrate of silver of known strength is then dropped in by means of the pipette. The whole of the chlorides in the urine have been obtained as soon as the *café-au-lait* precipitate of chromate of silver appears. M. Burot found that the normal amount of chlorides in the urine was eleven grammes for every litre, consisting of ten grammes of chloride of sodium and one of chloride of calcium. In tuberculosis it was estimated that seventeen to eighteen grammes of chlorides per litre were discharged. But a diminution of the chlorides is of greater import, especially in acute affections. In pneumonia, when the temperature is much raised, the fall in chlorides is considerable. This diminution was not noted in broncho-pneumonia. But in the pneumonia of typhoid fever at the onset of death the chlorides completely vanished.—*The London Lancet*, September 29, 1883.

ANIMAL ELECTRICITY.—Dr. McKendrick recently delivered a lecture on "Galvani and Animal Electricity," before the Southport meeting of the British Association (*London Lancet*, September 29, 1883). In summing up, the lecturer said that all electrical phenomena were really expressions of the vital changes occurring in living tissues under the action of stimuli. It was no part of the functions of nerves, muscles, or of the retina of the eye to produce electrical currents under the action of their relative stimuli; but such currents indicated chemical changes in the organs or tissues. For example, the contraction of a muscle is a movement following or consequent upon many chemical changes, among the results of which were the production of heat and differences of electrical potentiality. Thus, there was no special production of electricity except in the cases of electrical fishes, and possibly of some other animals. In most animals, including man, the production of currents was an incidental phenomenon, indicating chemical operations and nothing more. Besides, the currents so produced were feeble and evanescent, and bore no relation to the general well-being. Consequently, all attempts to influence the living body by magnets had no rational basis. It need hardly be said that the so-called phenomena of animal magnetism are of an entirely different kind from those discussed. These are of a subjective character, dependent on peculiar states of the nervous system, having nothing whatever to do with electricity or magnetism; but still in a sense they are phenomena as real as those of physical science. Their subjective character, however, renders them specially difficult of investigation, and consequently they are more liable to fall into the hands of the charlatan.

A NEW TUNE ON AN OLD STRING.—The following story is culled from the pages of *The California Medical Journal*, for October, 1883: "An old toper whose sober moments were harassed by a vixenish wife concluded to shuttle off, and loaded up with laudanum for that purpose. In a short time his wife discovered him in a state

of narcotism, and, raising an alarm, sent off every one who came in for a physician. The first one who came was Smith, an old practitioner, who looked him over, pronounced him dead, and went away. Soon after, another old practitioner, Brown, came in, who also gave in the verdict 'dead,' and departed. Shortly the third one, Jones, a young practitioner, arrived, and, proceeding to a vigorous use of the stomach-pump and forced exercise, finally succeeded in bringing the old gentleman to his senses, and left, feeling that there was but one first-class doctor in that vicinity. In a few days he called around and presented his bill. 'What's this for?' inquired the would-be suicide. 'For saving your life the other night,' replied Jones. 'Well, I didn't ask you to. I never employed you, and I'll not pay it. You'd no business coming in here and jamming your old pump down my neck. Brown is my family physician, and I'll not pay anybody else,' was answered. Then Jones went away to Brown's office to try and get him to induce the man to pay the bill. 'Jones,' said Brown, looking out over the top of his spectacles, 'I never thought you a bad sort of a fellow, but you've done a very foolish thing, and it serves you right to lose your bill. Didn't I say he was dead?' 'Yes,' says Jones. 'Didn't Smith say he was dead?' 'Yes,' says Jones. 'Well, that settled it. The man was dead to all intents and purposes, and you had no right to say that he was not. When two old experienced doctors like Smith and me say a man is dead, it's unprofessional and discourteous for a young man, a beginner in practice, to dispute their word. We'll forgive you this time, because of your youth and inexperience, and will hush the matter up for you, but be very careful in the future and make no more such mistakes.'"

THE EARLY TREATMENT OF FRACTURES.—Mr. Christopher Heath in the *British Medical Journal*, endeavors to induce surgeons to have more faith in the early treatment of fractures by plaster-of-Paris than appears as yet at all general, and thus to save their patients and themselves an infinity of trouble. In his paper he quotes from the "Aphorisms" of the late Dr. Cowling, of Louisville, the following, which he regards as full of common sense: "Carved and manufactured splints generally fit nobody, and are to be rejected, as not only expensive, but damaging." "The application of the roller-bandage immediately to the skin, whether as a protective or to prevent muscular spasm, has resulted in such disaster that it is one of the curiosities of surgery how it could be repeated at this day. When cotton is placed over such a bandage, it forms an absurdity scarcely credible in a man of ordinary sense." "Continued extension and counter-extension, are, as a rule, not necessary to prevent shortening in fractures. This is best done by removing the causes which lead to muscular spasm: 1st, by early and as complete reposition of the fragments as possible; 2d, by the smooth application of cotton-battling to the limb; 3d, by the equal pressure of a bandage extending from the distal end of the limb to a point beyond the joint above the fracture; 4th, by the accurate fitting of the splints or plastic material for support; 5th, by as little interference afterward as possible."

STEWED FRUIT FOR THE GOUTY AND DYSPEPTIC.—Dr. Milner Fothergill recommends the use of stewed fruits in many instances of gout and dyspepsia. Sugar is undoubtedly objectionable to many, but it is by no means necessary to add sugar to stewed fruit. If the acidity be neutralized by an alkali, little or no sugar is required. Thrifty housewives have long been familiar with the fact that the addition of a small quantity of bicarbonate of soda to stewed fruit reduces the acidity, so as to save the necessity for much sugar. If about as much bicarbonate of potash as will lie on a shilling (English) be added to each pound of fruit, it will be found sufficient to neutralize the acidity, and to bring out the natural sweetness. Milk puddings and stewed fruits are excellent for the dyspeptic, the bilious, and the gouty.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, November 10, 1883.

FRANCIS GALTON AND PROGRESS BY HEREDITY.

FRANCIS GALTON, in a recent remarkable work, has brought out many curious facts not in accord with common opinion. The qualities of men, according to him, are usually hereditary, not accidental, and life is a prolonged viriculture in which progress depends more upon marriage customs and birth-rates than on the institutions on which we are wont to plume ourselves. Our culture has gotten ahead of our brain capacity, so that only a small minority has the mental ability to profit by the advances which the leaders of thought have made. Two things, according to Galton, are necessary in order that civilization may move steadily forward: there must be a selection of the best, and a transmission of their qualities to their descendants. Where selection works, as it often does at this day, to attract the most vigorous to the cities, and reward them with success, accompanied with desires, cares, and vices which delay their marriage, and prevent their having children, it is positively injurious to the community. There is some immediate gain—more money made, or more books written; but the next generation is drawn from poorer sources, and if this process goes far enough, decay must set in. We must remember how often great nations have begun to rot in the height of their prosperity. We see Athens full of men of marvellous genius; but they do not marry, and at last their places are filled by slaves, retaining the Pyrrhic dance without the Pyrrhic phalanx. We see Rome, with a greater vitality, rising to be mistress of the world, but after a time her close family ties are sapped by luxury, and the same decay sets in. Her farms are depopulated and her fields are untilled. She calls in barbarians to fill her ranks, and falls before them from sheer exhaustion. The Ottoman Empire has gone through the same changes, and the danger is a threatening one to us to-day. In Australia and our own great West, the English race multiplies apace, but in New England the old families are dying out, and it is plainly falling back before the more prolific Celt; and in the South the blacks are multiplying nearly twice as fast as the whites; so that in another century, instead of being only half as numerous, they will have become two to one.

The only remedy which Mr. Galton points out is *stirpiculture*. The object of the better part of the community must be the elevation of their own family and race. Attempts must be made, and will be made when

a broader and more intelligent philanthropy prevails, to insure the fertility of the better portion, and the comparative sterility of the meaner portion of the community. If, he says, we are convinced that the only way of upraising a race is by securing the success of its best elements in the remorseless contest in which the strongest shall prosper, and hand down their traits to the next generation, while the weaker perish without leaving a trace, then the birth-rate becomes the most important test of progress, the pulse-beat of national life. The primitive passions for kindred and race are exalted again to the highest dignity; and thus we call to our aid two powerful emotions which the last century frowned upon, but which are yet among the most potent that sway mankind—family pride and patriotism. The man of health and ability who does not become a father is little better than a wrong-doer, from Galton's point of view, and the whole burden of his scheme is against the American ideal of home life, with its independent members so slightly bound to each other.

With regard to the treatment of paupers and criminals he is somewhat severe. The criminal class is generally infertile, but such instances as the Jakes family, with its five generations of criminals and paupers, show the danger. Imprisonment for life, or exile to a penal colony, where there is no intermixture of the sexes, would often be necessary, for crime becomes a disease to be stamped out, like the cattle plague. Pauperism would have much of the same character, and indiscriminate charity would acquire a new degree of wrongfulness. Indeed, the whole field of private charity and out-door relief would be much restricted, with a corresponding extension of the poor-house system. The reception of paupers and criminals from abroad becomes a wrong to the next generation, whose patrimony is squandered. The Chinese may increase our wealth, but wealth is not the object of living.

Galton's conclusions, in short, would kill out the Indian and the negro, and would make the extermination of the inferior races generally a virtue, if not a duty; and being opposed, as Mr. Holland admits, to our most cherished instincts, our purest aspirations, it is doubtful if, for some centuries to come, the race shall have become evolved to the point where the social science of this powerful thinker shall be law.

CEREBRAL MOTOR LOCALIZATIONS.

MM. CHARCOT and PITRES have just finished a series of articles (*Revue de Médecine*) in which they have analyzed one hundred and eighty-five cases illustrating motor localization in the cerebral cortex. The cases are all of comparatively recent date, and have been carefully reported. The conclusions which these observers draw are more definite and positive than any yet made. After analyzing in detail the cases supposed to oppose the doctrine of cortical motor localization, some defective point is found in all, and it is emphatically stated "That there does not exist a single rigorous observation of a destructive lesion outside the cortical motor zone which has caused permanent paralysis. That there does not exist a single rigorous observation of a destructive lesion involving these centres which has not caused a permanent paralysis on the opposite side of the body."

More specifically our authors announce the following very interesting and important conclusions :

1. The cortex of the cerebral hemispheres in man may be divided, functionally, into two parts : motor and non-motor, according as destructive lesions do or do not cause permanent paralysis of the opposite side of the body.
2. *The non-motor zone* comprehends : a. All the prefrontal region of the brain (orbital lobe, 1st, 2d, and 3d frontal convolutions). b. All the occipito-parietal region (occipital lobe, superior and inferior parietal lobules). c. All the temporo-sphenoidal lobe.
3. The *motor zone* includes only the ascending frontal and ascending parietal convolutions and the paracentral lobule.
4. The paralysis produced by destructive lesions of the motor zone have different clinical forms according to the location of the lesion. Thus, complete hemiplegias of cortical origin are produced by diffused lesions of the ascending convolutions ; partial paralyses are produced by circumscribed lesions of these same convolutions. The location of the lesion in some of these partial paralyses or monoplegias can be determined. MM. Charcot and Pitres announce the following as data for such determination : a. The brachio-facial monoplegias coincide with lesions in the inferior half of the ascending convolutions. b. The brachio-crural monoplegias coincide with lesions in the upper half of the ascending convolutions. c. The facial and lingual monoplegias depend upon very circumscribed lesions of the lower extremity of the ascending convolutions, particularly of the ascending frontal. d. The brachial monoplegias depend upon a very limited lesion of the motor zone ; particularly of the middle third of the ascending frontal. e. The crural monoplegias depend upon very limited lesions of the paracentral lobule.
5. Whether those paralyses caused by destructive lesions be general or limited, they will in time be followed by secondary contractures of the paralyzed muscles, with descending degenerations of the voluntary pyramidal tracts.
6. Irritative lesions of the cortex can give rise to epileptiform convulsions (partial or Jacksonian epilepsy), which are different from those of true epilepsy. They begin with a motor aura, and may be either generalized or limited.
7. In general the irritative lesions which cause epileptiform convulsions are located at or near those centres which, if destroyed, would cause paralyses in the muscles affected by the convulsion. But these lesions may be even in the non-motor zone, and their relation to the functionally affected centres is not so close as is that of paralyses and destructive lesions.

In conclusion the authors reaffirm their belief that no facts opposed to the doctrine of cerebral motor localizations have been established. Their own observations and studies, as shown above, do not so much add that which is new as they make definite and certain our previous views. They contradict, to some extent, the conclusions of Exner regarding the existence of diffused and overlapping centres. We are inclined to believe, however, that the method employed by Charcot and Pitres is more trustworthy than the unusual one adopted by Exner.

REV. DR. BUCKLEY AND NEWTON THE HEALER.

THE Rev. Dr. J. M. Buckley, the projector of the Methodist Hospital of Brooklyn, and the trenchant editor of *The Christian Advocate*, is doing a good work in making clear and definite the dividing line between the medical and clerical domain. He sharply supervises his advertising columns, much to the disgust of the omnipresent quack and the enterprising patent-medicine proprietor. In all our strictures upon the alliance between the religious newspaper and the healers who play upon the credulity of the gullible, we gladly except *The Christian Advocate*. The very few advertisements which to the profession may be "off color," and which appear at intervals in the weekly mentioned, are probably in fulfilment of old contracts over which the present editor had no control. In a recent letter having the deceased "Dr." J. R. Newton for its subject, Dr. Buckley states that he "had been acquainted with him for the past eighteen years, and had various conversations with him concerning his healing powers, and that he believed him to have been fully equal, as a healer, if not superior, to Dr. Cullis, Mrs. Mix, Miss Moseman, the Rev. Mr. Simpson, George O. Barnes, and vastly superior to the impostor, 'Dr.' Monck." He also says that "in 1865 there came to the city of Detroit, where the writer then resided, a pupil of Dr. Newton, 'Dr.' Bryant, who had an extraordinary career there, and performed cures apparently as well as Newton himself. In company with the Rev. J. P. Scott, a noted Presbyterian minister of that city, he visited him, saw him operate upon half a score or more of persons, and was operated upon himself."

A retarded voyage upon the Mississippi gave the editor, during the four days so spent, an opportunity of long conversations with "Dr." Newton concerning his career and principles of cure. He says that his conviction was that he believed in himself, and that he would use every possible means to accomplish the ends that he had in view. He saw that he could glide from fanaticism into hypocrisy, and from hypocrisy back into fanaticism, and from either into common sense and simplicity, with the rapidity of thought.

Newton told him that he was under the control of spirits, who impressed him what to do in every case. He saw him operate on a wen of small size, which had not visibly increased for the space of five years, on the head of a passenger with whom he was acquainted. He placed his thumb upon it, and pressing with all his power, and moving it sideways, he said, "I am impressed to paralyze that duct." This showed that he had some knowledge of the course of the growth of wens. (He learned afterward that the wen remained *in statu quo* for about two years, when it began to increase rapidly in size, and was removed by the knife of the surgeon.)

In the course of his narrative, Dr. Buckley says that he happened to mention having seen Dr. Bryant, when instantly Dr. Newton denounced Dr. Bryant as an "unmitigated fraud." "He has no genuine healing power." He claimed that he himself had cured Bryant of a malignant disease with which he had found him suffering in a hospital ; that the said Bryant had acted as his amanuensis for some time, and had then left him, and ever since acted in opposition to him. Knowing that the manipulations of Bryant had been followed by some

extraordinary results in Detroit, our editor said to Dr. Newton:

"Doctor, if Bryant is an 'unmitigated fraud,' how do you account for the cures he made?"

"Oh," said the doctor, "it is all accomplished by the faith of the people, and the concentration of their minds upon his operations with the expectation of being cured. Now," said he, "nobody would go to see Bryant, unless they had some faith that he might cure them, and the moment he begins his operations with great positiveness of manner, and when they see the crutches he has there, and hear other people testify that they have been cured, it produces a tremendous influence upon them. Then he gets them started in the way of exercising, and they do a good many things that they thought they could not do, their appetites and spirits revive, and, if toning them up can possibly overcome the diseased tendency, they improve, and many of them get well."

"Doctor, pardon me," continued the clergyman, "is not that a correct account of the manner in which you perform cures which are connected with your wonderful works?"

"Oh, no," said he, "the difference between a genuine healer and a quack like Bryant is as wide as the poles."

The inadvertent admission of "the healer" to his interrogator brings out the following remarks:

"His (Newton's) theory about the spirits suggesting things is simply a mystical description of the operation of the laws of association. Those laws furnish the Indians, the Turks, the Hindus, and the old Scotch poets of Ossian's (?) time with their poetry, the harpers of Ireland with their music, Patrick Henry with his eloquence, the spiritualists with their nonsense, and exhorters and extemporaneous preachers and orators with their language, though a belief in either spirits or supernatural aid is a wonderful stimulant to their action.

"As Christians we believe that the Holy Spirit has constant access to our hearts and minds, moving upon us by arousing our emotions and stimulating and guiding our thoughts through the natural laws of mind. Thus we expect and rely upon His aid. To expect Him to give ideas *ab extra*, as these spiritists claim, and as Newton told me, is, as Wesley and all rational Christians have shown, fanaticism, ending in Antinomian debauchery or insanity."

Against this logic, we have naught to say—it has a Baconian ring about it. Were all our clerical brethren less ready to endorse "faith cures" as such, there would be no room for certain extravagant devices on the part of those who seek to unite the functions of both professions. We therefore congratulate the Rev. Dr. Buckley as being a pioneer in an almost unexplored territory.

THE DISEASE OF THE POTATO DIGGERS.

DR. W. ZENKER, of Stettin, has recently given a description (*Berliner Med. Wochenschrift*) of a "new disease" which affects farm-laborers, particularly those engaged in digging and gathering potatoes. Dr. Zenker calls it a "new disease" in the sense that it has not before been described. He believes, however, that it must have existed for a long time among the peasantry of Germany and all agricultural regions. The disease is

thought to be a neurosis of the locomotor apparatus of the feet and legs, the thighs and trunk not being affected. It is caused by the peculiar strained position into which the legs and feet are thrown while digging and gathering potatoes. The laborer, says Zenker, stoops down and supports himself upon the knees and feet. He moves about in this position with the knees strongly bent and feet strongly extended, and he keeps at this for hour after hour for many successive days. The position is not a natural or easy one, and any beginner who attempts it will soon feel a weariness and numbness in the limbs.

The result of this kind of labor is that in some cases one or both feet and legs become paretic, the paresis affecting both motion and sensation. The patient finds that one extremity feels heavy, cold, numb, and sometimes painful, and the foot drags in walking. The physician on examining it finds that the movements of flexion and extension are slow and weak, lateral motion is limited. The affected leg feels colder to the touch than the healthy one. Tests show a loss of pathic and tactile sensation almost complete. In some cases electric currents are but slightly felt, while both faradic and galvanic reactions, though present, are feebler than normal. The leg does not atrophy.

A case of this kind may rapidly improve, or it may continue almost in *statu quo* for several years; the patient still walks about, though with a limping gait. The treatment has, so far, consisted in foot-baths, massage, and electricity. It has not always proved successful.

Dr. Zenker reports in detail only five cases, but he believes that the disease cannot be a very rare one in the autumn months, and begs that other physicians practicing in the country will report the results of their observations.

We are unable to say whether any such affection as Zenker describes exists in this country. It has not been described as yet in any American text-book. It would be a matter of interest to know whether any of our readers have come across the disease.

THE GROUND FOR STATE INTERFERENCE IN REGULATING MEDICAL PRACTICE.

PROFESSOR HUXLEY, whose great scientific attainments have not evolved any false modesty as to the value of his own opinions, has set our English brethren by the ears in the matter of medical reform. In an address delivered recently at the London Hospital he speaks kindly of the Medical Council; he advises a preliminary technical rather than general training, and urges a greater specialization of teaching and of the profession. All of this is badly received by the medical journals, and the address is mildly censured as a "vacation effort."

But apart from these particular points, which have no great interest here, Professor Huxley touched upon another subject, which is of very great moment. This was the subject of the relation of the State to the medical profession. Upon what ground has the doctor a right to ask the State to interfere in the matter of regulating medical practice? is the question which he puts to his hearers.

Now, in many of the States at present efforts are making to secure the intervention of Government and the regulation of medical practice. It is important that

the reasons for making this demand be distinctly understood.

The ground for State intervention, according to Huxley, is not the protection of the public against incompetency or quackery. If such protection were advisable, he says, it is not practicable, as it would be impossible to prevent any one from buying drugs or seeking advice of whom he pleased. The right of the State to intervene is based on the fact, first, that it is of great importance to the community that no man shall die without the cause of his death being formally certified; second, that the law shall be able to appeal to recognized experts in civil and criminal cases; and, third, that the Government shall have a guarantee of the competence of persons appointed to the numerous medical appointments at its disposal. It is no interference with the freedom of medical practice if the Government says to the medical practitioner, "We will not accept your certificate of death; we will not regard your evidence as that of a medical expert; and we will not take you into our service unless you produce evidence which satisfies us of your medical competency."

The reasons thus expressed are, we believe, legitimate and unanswerable; but it follows that in order to make the people feel the need and justice of regulating medical practice, they must also appreciate the value of a registration of vital statistics. The further statement of Professor Huxley that a government cannot and should not attempt legally to protect itself against quacks is somewhat too strong. Not long ago a well-advertised quack in this city killed a man with an overdose of mandrake. Why should not Government apply preventive medicine to ignorant charlatans such as this man as well as to typhus fever?

THE MURIATE OF LIME IN THE TREATMENT OF SO-CALLED SCROFULOUS TUMORS.

OLD, but good remedies are often forgotten in the pursuit of the new. In Dr. James Sanders' treatise on scrofula and consumption, page 112, we read: "I think I have ascertained that the muriate of lime has a more powerful effect in removing indolent scrofulous tumors than any other substance used as remedy; but that when they become open sores it is almost useless. It is a very manageable substance, the dose of which may be gradually increased from five or six grains three or four times a day to two drachms in the twenty-four hours. And I have never observed it produce any disagreeable effects, except of the slightest kind, and then only after its use had been long continued and the quantity of the dose had become very great." Dr. Sanders' book was published in 1808, and he was one of the presidents of the Royal Medical and Royal Physical Societies of Edinburgh. He continues: "Six years ago I observed with admiration its effects in a young lady, who was so disfigured by these swellings that the apex of her head was that of a cone resting on her shoulders. During the use of the muriate for six months her neck resumed its proper shape, and there scarcely remained an unusual enlargement of any gland; and since that time I have never seen it administered in similar circumstances without producing beneficial effects. I have tried it frequently and

think it has always proved useful, sometimes eminently so. A young gentleman, aged nineteen, had the glands of his neck very much enlarged from his infancy; his skin was rough, fissured and oozing [with eczema], and he had all the pulmonary signs of incipient phthisis, with frequent attacks of hæmoptysis. During the use of the muriate for several months, the skin healed, the glands diminished in size, the pectoral complaints were removed, and the strength of his body was improved. A girl of nine years had the glands of her neck somewhat, but the parotid and tonsillary glands enormously enlarged, so that the latter seemed almost entirely to fill the fauces. She had occasional attacks of dyspnoea, teasing cough, copious expectoration of transparent, clammy, or frothy matter, when she began to take five grains of the muriate in solution, twice a day, and gradually increased the dose. The swellings soon diminished, and the pectoral complaints were much mitigated. At the end of six months she was taking nearly two drachms of the medicine a day, and seemed nearly well; three drachms seemed to cause squeamishness at the stomach, and the quantity was therefore lessened. She continued to take small doses for a year, when the visible tumors had almost disappeared, while the signs of the internal affection had significantly decreased."

MEDICINE IN MISSISSIPPI.

SOME time ago we called attention to some of the peculiar features in the practice of medicine in Missouri, as depicted with an honest and unsparing hand by the President of the State Medical Society. Our editorial received wide notice, and we have reason to believe that it produced much good, more especially in awakening other States to a little introspective study.

There has appeared in the *Mississippi Valley Medical Monthly* an article from the pen of Dr. G. S. Holmes, of Benton, Miss., entitled "The Medical Profession in Mississippi," from which we gather that medical practice in that State is in a not much happier condition than it is or was in Missouri. Dr. Holmes writes with much more than ordinary eloquence and force, and the picture which he draws, if in any way a true one, certainly deserves earnest attention.

There are in Mississippi about 1,800 doctors in a population of 1,200,000. This gives a ratio of 1 to 666, which shows that the doctors are quite numerous for a State which is not wealthy, and which has not a large population. Last year the Legislature passed a bill "to regulate the practice of medicine," and some congratulations have been extended upon the fact. Dr. Holmes, however, deplors it. The peculiar legal verbiage, he says, of the section calling for a license, made it *compulsory* upon the State Board of Health to issue a *license to every applicant* without regard to qualification, provided that "such application was duly sworn to, and accompanied, honored and substantiated, dignified and glorified by the paltry sum of ten cents." Under this section, therefore, nearly all of the one thousand eight hundred practitioners have obtained a license and are regularly constituted physicians, while, in Dr. Holmes's opinion, "two out of every five of this number are totally unworthy of the privilege." "We know," he says, "of no less than a half dozen M.D.'s in a radius of ten miles,

who, having failed generally at their former trades, have taken up the less honorable one of Mississippi medical practice."

"In the good old ante-bellum days," he continues, "of wealth, independence, and luxury in the South, the medical practitioner was regarded as possessing something of more than ordinary social status; not because his pocket jingled with the dross by which now a gentleman's principles and virtues are estimated, but from the less adulterated worth which attaches itself to moral and intellectual culture. The title of M.D. commanded respect from its significance alone, because it was but exceptionally deserving of it. But alas! the change 'twixt then and now. It is true that we are as yet in the wake of a terrible revolution, but can that explain the retrogradation of the poor commercial *trade* of to-day, which once characterized the intellectual, moral, social, and professional dignity of Mississippi? Ignored by the civil laws and unprotected from imposition, it is a compliment to the medical practice in this State to be admitted a respectable trade. There is not practised in the Union to-day an avocation of more subjection, servitude, and dependence than that of medicine in Mississippi. Under the civil laws of the State, a doctor is expected to do his practice for almost less than gratitude, and to place his claim for services upon the charity of the ungrateful, while he is ostracized and abused for exorbitance in his price, and taxed beyond his capacity to pay on the profits (?) of his profession. Ignored in all things else, he is never forgotten when needed in the *harangues* of petty courts for that professional opinion which he has made valuable to himself by years of laborious toil and study, to say nothing of the outlay of money."

We trust that our eloquent author looks too much upon the dark side. If he does not, there is need, as he says, that the profession organize for its own protection.

FATAL CATHETER FEVER.

At the opening meeting of the Clinical Society of London, Sir Andrew Clark made a communication of much interest upon the subject of what might be called "Fatal Catheter Fever."

He said that in 1870 a man, who was otherwise in good health, consulted him for slight incontinence of urine. He consulted a specialist, who found his prostate enlarged and his bladder unable to empty itself, and advised him to use a catheter. Four days later he was taken ill; the urine contained a little pus; pulse, 120; temperature 100°. After two days the temperature rose higher, the pulse became more frequent, and in eight or nine days he died; the bladder was inflamed, and the kidneys were reported to be healthy. Since 1870 Dr. Clark had seen four or five such cases every year. He had not been able to gather sufficient information on this malady, which was not very uncommon. He was not alluding, of course, to the slight rigors after catheterism, but to a fever which generally ended fatally.

In commenting on this class of cases the *Lancet* states that they do not occur in men who have been previously free from disease of the urinary organs. There is a history of chronic stricture, enlarged prostate, and vesical atony. The suggestion is made that there is, with this,

a chronic interstitial nephritis affecting especially the cortex. The slight irritant effect of catheterization sets up an acute nephritis, which ends in suppuration and causes death.

The "fatal catheter fever" is not, according to Dr. Clark, very uncommon.

News of the Week.

A SCOTTISH WEEKLY MEDICAL JOURNAL.—A weekly medical journal, called the *Edinburgh Clinical and Pathological Journal*, has been issued in Scotland, Drs. Graham Brown, Cathcart, and D. Bery Hart, being editors.

THE GERMAN CHOLERA COMMISSION.—Dr. Koch has applied for permission to continue his researches into the nature of cholera in India. This permission has been granted him by Bismarck, and he will start for Bombay when his work in Egypt is finished.

WOMAN'S MEDICAL COLLEGE OF THE NEW YORK INFIRMARY.—Dr. William O. Moore has been appointed Professor of Eye and Ear Diseases, in place of Dr. Charles Stedman Bull, resigned.

FLIGHT OF A BOGUS PHYSICIAN.—The daily papers state that W. H. Coney, who for three years past has been running a bogus medical college in Milwaukee, Wis., despite all efforts of the authorities to suppress the concern, has decamped, deserting his family. He was a hostler to a surgeon in the British Army, and gained some slight knowledge of medicine. He secured a bogus diploma, and soon after his arrival in Milwaukee began practising medicine. He opened a medical college, and turned out about sixty graduates, the most of whom are practising illegally in Wisconsin and Minnesota. Coney's bogus concern, through some hocus-pocus legislation, secured a charter from the Legislature, and all efforts to suppress it proved futile.

SURGEON-GENERAL JOHN B. HAMILTON, U. S. Marine Hospital Service, has been tendered the Chair of Surgery in the Georgetown Medical College, and signified his acceptance of the same, having resigned a similar position in the Medical Department of Columbia University which he was temporarily filling during the absence of Prof. J. Ford Thompson in Europe.

DR. JAMES R. LEWIS, the oldest physician of Luzerne County, died at his home in Trucksville, Pa., on November 3d. He had been in continuous practice since 1832.

MEDICAL STUDENTS IN THE LONDON SCHOOLS.—The lists show the matriculation of six hundred and ninety-three new students in thirteen medical schools, St. Bartholomew's and University leading.

EDINBURGH UNIVERSITY has nearly reached its three hundredth anniversary. In 1883 its students numbered three thousand three hundred and forty, and when its new buildings are completed it will be the largest university in the world.

ANOTHER SUCCESSFUL RESECTION OF THE PYLORUS.—Dr. Viktor V. Hacker, of Vienna, reports in the *Wiener Medicinische Wochenschrift* another successful

case of resection of the pylorus. The patient was a woman forty-six years of age, who had suffered from symptoms of pyloric disease for only a year. In June, 1883, the diagnosis was easily made of cancer, a tumor being felt. Billroth operated. The woman recovered, and is now (October) well.

PROFESSOR ACLAND, of Oxford University, has been made a Companion of the Order of the Bath. This has nothing to do with Professor Acland's contributions to hydrotherapy.

THE PHILADELPHIA MEDICAL CLUB is the title of a new Society recently organized in Philadelphia.

A CONGRESS FOR THE DISCUSSION OF CHOLERA QUESTIONS was held in St. Petersburg last month.

THE HEALTH OF THE ARMY; THE ARMY MEDICAL MUSEUM AND LIBRARY.—The report of the Surgeon-General of the Army for the fiscal year ended June 30, 1883, prepared by the late Surgeon-General Crane, has been made public. In a chapter on the health of the army during the fiscal year, the report says: "Among the white troops the total number of cases of all kinds taken on the sick list was 37,697, being at the rate of 1,802 per 1,000 of mean strength, an increase of 123 cases per 1,000 over the number reported for the previous year, and 68 per 1,000 over the average decennial rate of admission. The total number of deaths from all causes reported among the white troops was 214, or 10 per 1,000 of mean strength. The total number of white soldiers reported to have been discharged from the service for disability was 879. Among the colored troops the total number of cases of all kinds reported was 4,689. The total number of deaths of colored soldiers reported from all causes was 26. The total number of colored soldiers reported to have been discharged for disability was 101. The total number of cases reported among the Indian scouts was 44, and the total number of deaths was 2. Diseases of the respiratory organs stand first in numerical importance, of which about sixty-four per cent. are catarrhs of the upper air-passages. Extremes of variation in temperature will account in part for the frequency of these diseases, but to a larger extent insufficient ventilation of barracks and dormitories, as well as irregular and unequal distribution of artificial heat during cold weather, must be held responsible. Wounds, injuries, and accidents stand second on the list of causes impairing the effectiveness of the army. The large number recorded in this class may probably be attributed to the use of troops in mechanical and laborious employments, which form so large a proportion of the soldier's duties. As an indication of the peculiar hardships to which our troops are exposed, the rates of admission for wounds, accidents, and injuries are 122 per 1,000 higher than those reported for the German army, and 142 per 1,000 higher than the decennial rate of the British army. It is interesting to note that the colored troops make a particularly favorable showing in the small number of admissions for alcoholism and its results, exhibiting, as they do, a rate of only 4 per 1,000 to a rate of 76 per 1,000 of mean strength among the whites. On the other hand, in diseases of the nervous system they have an unexplained preponderance. The number of recruits reported to have been examined by army

medical officers and private physicians during the year is 5,964 white, 426 black, and 247 Indian scouts. The total number of rejections was for white 2,063, or 346 per 1,000 of the number examined, and for black 131, or 307 per 1,000; Indian scouts, none.

The additions to the library during the past year include 3,912 volumes and about 5,000 pamphlets, making the total number in the collection about 60,000 volumes and 68,700 pamphlets. Six hundred and thirty-eight specimens were added during the last fiscal year to the collection of the Army Medical Museum. Ninety-four of these were purchased, and 544 were contributions either by medical officers of the army or by civil practitioners and other citizens.

A DEPARTURE IN FRENCH JOURNALISM.—It is very rare that French journals take any notice of medical events in other countries than France. In a recent issue of *Le Progrès Médical*, however, appeared a very good account of the meeting of one of the sections of the "Association Médicale Américain," at Cleveland last June.

THE NEW CZECHISH UNIVERSITY at Prague is already in trouble. The students of the Bohemian and German schools are at odds and frequently quarrel. Lately the ill-feeling has extended to the Bohemian and German midwives, who are quarrelling over their teachers. Facts seem to justify the fear that the establishment of the new University would injure the peace and harmony of medical Prague.

THE YELLOW FEVER has about disappeared from the United States, but continues to hold sway among the Pacific coast States of Mexico. Assistant Surgeon Main, U.S.M.H.S., reports that the following Mexican cities and towns are suffering with the disease: Guaymas, Bazos, Jalisco, Manzanillo, Ixcatlan, Atar, Yuki, Altata, Acapulco, San Blas, La Paz, Culiacan, Mazatlan, and a number of the villages near the mountains. It has been particularly fatal among miners. In one camp of a hundred miners only nine are reported to have escaped death. In La Paz five thousand cases were reported up to October 28th, but the mortality was not given. The Governors of the infected States are taking the matter in hand and have issued very stringent orders against exhuming those who have died of yellow fever, and are doing everything possible to alleviate the suffering of their people by ordering free burials, paying the expenses of the sick poor, etc.

Sanitary Inspector Mainegra reports from Vera Cruz the inspection of the following named vessels bound to United States ports, up to October 28th: steamer City of Alexandria for New York, bark St. Cloud for New York, steamer California for New Orleans, bark Chapman for Galveston, bark Keewarden for Mobile, steamer City of Mexico for New Orleans, schooner Seguin for New Orleans, schooner Forest Home for Pascagoula, steamer Whiting for New Orleans, steamer City of Washington for New York—all in good sanitary condition.

Sanitary Inspector Burgess reports from Havana the inspection of the following named vessels bound to United States ports, up to October 27th: American schooner Nonpareil for Key West, Spanish brig Vilasar for Charleston—seventy days in port, twenty-five at a suspicious wharf, vessel disinfected; Spanish brig Maria Teresa for

New Orleans—fifty-four days in port, thirty at suspicious wharf, disinfected; Spanish brig Guadalquivir for Doboy, Ga.—thirty days in port, twenty-one at suspicious wharf, disinfected; American steamer Niagara for New York, American steamer City of Alexandria for New York, and schooner Grover G. King for Key West; Spanish steamer Pedro for Charleston, disinfected; Spanish steamer Apolo for Savannah, disinfected—these last two vessels were not at dock in Havana, but were from infected ports of Cuba previously, and were disinfected at request of their masters. There were twenty deaths from yellow fever at Havana during the week ending October 26th.

A NATIONAL HYGIENIC CONGRESS was held in the City of Mexico on October 10th, at which a petition was prepared for presentation to Congress, asking that the Constitution be amended by the addition of an article placing all sanitary regulations under the jurisdiction of the general Government. The proceedings of the Congress have not yet been received.

The State Department is in receipt of letters from the consuls at La Paz and Mazatlan, Mexico, dated October 18th, giving brief statements of the epidemic of yellow fever in their respective consulates. At La Paz the disease was very malignant during the month of September, there being 114 deaths from yellow fever, out of 122 from all causes. The Board of Health deserted the city for the mountains, and all communication with the outside world was cut off, so that exact facts are difficult to obtain, but it is known the disease was wide-spread through that section. The yellow fever at Mazatlan had about disappeared, and clean bills of health are furnished vessels sailing from that port.

Gibraltar has modified its quarantine restrictions, and now allows vessels sailing from the Brazils to coal under certain regulations. All vessels sailing from Gibraltar are required to provide themselves with a bill of health in such form as shall from time to time be ordered by the Board of Health, and as the circumstances in each case may seem to require.

Bermuda has had new quarantine regulations "made by his Excellency the Governor," under date of October 19, 1883. The islands are divided into two districts—Eastern and Western—and a health officer is placed in control of each. The gist of the regulations is contained in the sixth section: "Any health officer visiting any vessel arriving from a proclaimed port, and finding that there is no contagious or infectious disease on board, and that there has not been any such disease on board for one calendar month previous to her arrival, and that such vessel has not during that period held communication with any vessel on board which there was any such disease, or with any port or place at which such disease prevailed, may grant her *pratique* at once if satisfied it may be granted with safety to the health of these Islands, but if not so satisfied shall place such vessel in quarantine of observation for such time as may be necessary to enable him to determine whether she shall be kept in quarantine, or may be released with safety to the health of these Islands."

PERSIA AS A HEALTH RESORT.—Consul Benjamin, of Teheran, Persia, sends to the State Department an interesting account of the climate of Persia. He states

that during the past summer that country has been healthy and free from any but sporadic cases of the plague.

As regards the climate of Persia, he writes: "It may be called, beyond question, one that is generally conducive to a high average of health. The rice-growing provinces of Mayanderan and Gilan, north of the mountains and bordering on the Caspian Sea, are full of malaria and fevers of a malignant type. The natives, however, do not seem to be affected by it, except in the matter of chills and fever.

"In the neighborhood of the Persian Gulf, the intense heat, rivalling that of India, while tempered by the trade winds, is very relaxing, although not necessarily fatal to foreigners. But for the most part the kingdom is one of remarkable salubriousness. Persia consists of an immense plateau elevated an average of four thousand feet above the sea. This is intersected by numerous lofty, rugged, and barren ranges, soaring sometimes to sixteen thousand feet above the sea level. Eternal snow exists on their summits. The vast plains are generally covered with dense verdure, and are fed by the artificial currents brought from the mountain springs. The winter is short but characterized by high winds, and in many of the northern parts by violent snow-storms. The spring and autumn are mild and delightful. The summer is indeed hot, but the nights are always tempered by cool mountain breezes. By August 20th, the cooler weather of autumn commences. At Teheran, during this summer, the thermometer has ranged from 90° to 110° F. in the shade, but the air has been excessively, and uniformly dry. In the cluster of villages, nine miles from the city and thirteen hundred feet higher, at the foot of the mountains, called the Shiniran, or Light of Persia, the mercury has ranged from 75° to 90° F. in the shade at midday, rarely going above 85°, and falling to 70° at sunset.

After once becoming acclimated by the assistance of quinine, and the exercise of common sense in general habits, Europeans find such a climate healthful and agreeable. It is evident that with only ordinary knowledge and prudence, the average length of life of the native population could be greatly increased. There is a steady, although slow growth of the population. Phthisis is exceedingly rare. Small-pox exists, but determined efforts are made to increase the advantages of vaccination. The greatest mortality is among young children, resulting from uncleanness and carelessness in diet. Venereal diseases are widely spread and tend to perpetuate chronic and hereditary disease, especially affections of the eye. Notwithstanding this, however, the people are handsome, finely formed, and capable of great endurance. With mere regard to sanitary precautions, Persia might be regarded as one of the healthiest countries on the globe.

With the exception of the provinces above mentioned, it offers no dangers to the health of Europeans who do not indulge in dissipation, or who take ordinary care of themselves. It can be especially recommended to those afflicted with pulmonary complaints, provided they do not delay coming until the overland journey is too severe for their strength, a precaution too often disregarded by invalids as well as by their medical advisers.

CHOLERA IN CHINA.—It is reported that cholera has appeared in epidemic form in Peking.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, November 1, 1883.

FORDYCE BARKER, M.D., LL.D., PRESIDENT, IN THE CHAIR.

DR. JOHN G. ADAMS, after the reading of the minutes, read a protest against the ruling of the President at the last stated meeting on the motion to rescind the resolutions adopted by the Academy in April, 1883. The minutes as read by the Secretary were adopted with the protest. The protest, on separate motion, was laid upon the table.

DR. ADAMS, Corresponding Secretary, announced the death of Frederick D. Lente, M.D., a corresponding Fellow.

THE PRESIDENT paid a touching tribute to the memory of Drs. Lente and Charles Wright, both of whom had prepared papers, to be read before the Academy within the coming winter, having a strikingly similar title. The paper prepared by Dr. Wright was on "The Duration of Life after the Appearance of Albumen or Sugar in the Urine," and that prepared by Dr. Lente on "The Duration of Life as Affected by Climatic Influences in Consumption."

DR. T. HERRING BURCHARD then read a

MEMOIR OF THE LATE FREDERICK D. LENTE, M.D.,

which was an appropriate tribute to the untiring energy, the scholarly acquirements, the sterling integrity, and the stable friendship of the deceased.

DR. F. N. OTIS then read a paper (see p. 480) on

THE RAPID EVACUATION OF STONE FROM THE BLADDER AFTER CRUSHING, WITH PRESENTATION OF A NEW AND SIMPLIFIED EVACUATOR.

THE SECRETARY read a letter from Dr. James L. Little, whom the President had invited to participate in the discussion of the paper, but who had been unavoidably detained by professional engagements. Dr. Little referred to the great value of rapid lithotripsy and his success in its performance on old men who had suffered from urinary calculus for several years.

DR. E. L. KEYES opened the discussion, and said he thought the instrument devised by Dr. Otis was an admirable piece of apparatus, although he had not had an opportunity to test its practical working.

With reference to tolerance of the bladder to instruments he thought that was most satisfactorily demonstrated by Heurteloup, Civiale, Le Roy, d'Etiolle, and others. Civiale finally reduced the time to three minutes, and Sir Henry Thompson, using Civiale's data, had made the length of time of a single sitting not more than three minutes, and had shortened the intervals between operations. Up to Clover's time the instruments devised were designed for use in atonic bladders. The use of the large tube was due to Professor Otis. But the size of the tube is not at all essential, and he did not regard it as the key-note of the advantage of rapid lithotripsy. He did not regard any single thing as the essential in the operation. It was the crystallization of all the ideas in the brain of Professor Bigelow that made the operation distinct in itself. Bigelow thinks that the large tube is essential, but Dr. Keyes regarded many things as essential in order to make the operation successful. Dr. Keyes believed the operation can be performed with a No. 12 perfectly well, and was unable to see any particular advantage in using a larger tube to save a little time. The element of time has been thrown out by Professor Bigelow. According to Dr. Keyes' experience the use of a large tube had sometimes been followed by cystitis, and in cases in which cystitis did not follow the use of a smaller tube.

He thought it best not unnecessarily to distend the urethra. He took the point of second constriction of the urethra, about two and one-half inches from the meatus, as a guide for the size of the tube. One which will go easily through this portion of the urethra he regarded as the more appropriate size.

He was charmed with the efficiency and simplicity of the design of the apparatus exhibited by Dr. Otis, and should use it when the next opportunity presented itself. The instrument he used entirely was that with a strainer, and he had not been obliged to change the strainer during the operation. He thought it possible that the quantity of air which Dr. Otis' apparatus contained might be an objection, and suggested that if it could be used upside down the air in the tube could be gotten rid of.

DR. OTIS—It can be used in that way, and indeed it is the way in which I usually use it.

DR. KEYES then described Thompson's manner of using his instrument, and also his own method. Bigelow, Otis, and Reginald Harrison, of Liverpool, he thought were the only operators who used a large tube. If the tube is introduced into the bladder at once, of course a quantity of air may be carried in, and to avoid this he carries it down into the prostatic urethra only, then makes gentle pressure upon the bulb, which forces the air out, and, while this pressure is maintained, pushes the tube on into the bladder. As it enters the resistance offered at the end of the tube is quickly removed, the pressure causes the bulb to collapse completely and send a full stream of water into the bladder. Then make short washings; that is, squeeze the bulb lightly, and not give it a full grasp, which completely empties it. The bulb of Dr. Otis' instrument was small, and perhaps it would prove to be one of its greatest advantages.

It sometimes occurs that water escapes by the side of the tube, and as Dr. Otis' instrument then stood it might be that it did not contain sufficient water, and for replenishing could not be so well managed as Bigelow's. However, these objections could be very readily overcome, and doubtless had been anticipated already. But for cheapness, portability, transparency, and simplicity it excelled any which had yet been devised. Whether or not fine phosphatic dust would be thrown back again he could not say; but after all, if it was, it would not make any special difference as it readily passes out with the urine.

DR. OTIS thought that Sir Henry Thompson might be regarded as one who uses a large tube, because he employs as high as 28 or 30, certainly as large as the average of what he had just recommended. He agreed with Dr. Keyes concerning the disturbances liable to be set up by using a large tube in cases in which the prostate is enlarged; but, at the same time, he was unable to see why we should not have the advantage of the full size of the normal urethra when the prostate is not diseased. He believed division of the meatus was important in a majority of cases, and it should be performed beforehand, for the reason already given and for another, namely—that many of the irritations which have previously existed, and which simulate stone in the bladder, pass away after division of the orifice of the urethra.

With reference to the size of the bulb, he thought the smaller one desirable for the sake of portability, and besides it was least liable to get broken. Dr. Otis then demonstrated how the evacuator could be manipulated so as to meet the suggestions made by Dr. Keyes.

THE PRESIDENT then declared Drs. R. W. Taylor, C. H. Judson, R. W. Amidon, M. Josiah Roberts, and L. Emmet Holt elected as resident Fellows, after which the Academy adjourned.

THE MEMBERS OF THE PASTEUR MISSION TO EGYPT have returned.

Correspondence.

OUR LONDON LETTER.

(From our own Correspondent.)

OPENING OF THE WINTER SESSION AT THE LONDON HOSPITALS.—RELATION OF MEDICINE AND OF SCIENCE TO RELIGION—TONE OF THE INTRODUCTORIES—STATEMENTS ON RELIGION BY PROFESSOR ACLAND, DR. HANDFIELD JONES, F.R.S., MR. LE GROS CLARK, AND MR. GOULD—PROFESSOR FLOWER AND MR. CLARK AT THE CHURCH CONGRESS.

LONDON, October 10, 1883.

THE new session has opened with, perhaps, unusual success. The dissecting rooms are well supplied with subjects, and the schools are—at least the majority are—rejoicing over full entries. The opening day was this year remarkable for the tone of the introductory lectures. It has long been the custom at each school to open with an introductory lecture, professedly addressed to the freshmen, but inasmuch as the occasion brought together a large number of former students at the school, it was generally seized to speak to them also, and therefore the lecture was looked forward to as the event of the *annus medicus*.

A few years ago the daily papers began to report these annual lectures, and to this is perhaps partly due the fact that they have taken a wider and wider range of interest and importance. The public regards them as the exposition of medical opinion for the time being, so that if the lecturers were some year to meet beforehand and all agree to demand some right or the redress of some grievance, their united voice would perhaps be regarded as necessitating the change. At present variety characterizes the lectures, all subjects being deemed to come within their cognizance, on the principle, I suppose, of *nihil humani alienum puto*.

This year the introductions are remarkable from the fact that several lecturers have ventured to touch on the topic of religion, and show that true science is not in opposition. Considering the bold assertions which materialists have of late years made, it is refreshing to hear the other side from men of high standing in our profession. At King's College this seemed natural enough, as it was founded as a defence of orthodox views, to be carried on as a Church of England institution in contradistinction to unsectarian colleges.

Professor Acland, of Oxford, came up to deliver this lecture, and as he is President of the Medical Council, this official position, as well as his own learning and influence, would lend weight to his utterances. Admitting that the arguments of materialists were intricate as well as voluminous, and that often in the past the faith of religionists had rested on ignorance or superstition, he held that the progress of science had not in the least shaken religion, and pronounced the controversies respecting the relations between the two as the most fruitless of all except possibly purely metaphysical speculations. There spoke the physicist, will no doubt cry the philosophers. Dr. Acland quoted a beautiful passage from Dr. Latham (whom he pronounced one of the greatest clinical teachers this metropolis ever saw) to show the spirit in which students should master their work and stand related to their fellow-men. Latham said that when humanity warms the skill of the consummate practitioner, the interest, excitement, and intellectual pleasure of helping the sick, is "exalted into a principle and invested with a moral motive, and passes into the heart." Then asking, "What if religion should animate it?" he answered, "Why, then, happy indeed is that man whose mind, whose moral nature, and whose spiritual being are all harmoniously engaged in the daily business of his life; with whom the same act has become his own happiness, a dispensation of mercy to his fellow-creatures, and a worship of God."

Reminding his hearers that as Latham spoke, so he lived, and so he died, Dr. Acland proceeded to urge that too often, unhappily for mankind, the human element is permitted to overshadow the divine and the form allowed to seem more important than the substance. And yet, he said, the "essentials of spiritual life are simple enough. They may be and are hard to teach and hard to attain. They are taught chiefly by example, which implies individual attainment. They are acquired by practice, which means individual self-sacrifice." Then making his climax in Greek, as well became the Oxford professor, but might be, to a large extent, lost on a modern medical audience, he added: "They are summed up in those weighty words, *μετάνοια, πίστις, ἀγάπη*. These gifts, we are told, are not self originated—having life, they are born of other life, *ὁ καρπὸς τοῦ πνεύματος*." Then he said any education which has not brought before the student considerations of this spiritual life has been faulty and inadequate for him. "Any scheme of the universe condemns itself which leaves out of sight all that can be learnt of the character of a Heavenly Father from the study of the moral nature of man."

Dr. Acland was not alone—not even perhaps the most outspoken in raising the standard of orthodoxy which has this year been waved triumphantly at several of these introductory lectures. Thus, at St. Mary's Hospital, the veteran senior physician, Dr. Handfield Jones, F.R.S., devoted a considerable portion of his lecture to warning the students against prevalent forms of skepticism, and showing the evidences which he thought sufficient to establish the truth of Christianity and the historical truth of its great central miracle—the resurrection of Jesus Christ.

Again, at St. Thomas' Hospital, another venerable F.R.S., Mr. Le Gros Clark, delivered similar testimony to his confidence in a causative, intelligent law-giver, "beneficent and omnipotent, 'too wise to err, too good to be unkind.'"

To these examples I may add that one of the later generation—one of the young surgeons who may be regarded as a rising man, also gave no uncertain sound; for having dwelt at length on Nature, he commends her to the diligent study and to the imitation of his hearers, adding as a conclusion: "You will find that however secret her plans may be, when they are discovered and brought to light, they are such as only to excite our admiration as worthy of a God. Imitate her in this, too, and the pure in heart shall see God."

Many other topics were touched upon by the several lecturers, but the one I have considered has perhaps excited the most remark, as indeed it could not fail to do, as its interest is wider, deeper, larger altogether, affecting in fact all the race of mankind.

The lecture at the London Hospital was this year postponed to the 9th instant. Professor Huxley was the lecturer, and it was thought by some that, having thus nine days' notice, so to say, of the drift of medical opinion, he might attempt something in the nature of reply, or, at any rate, what might be so construed. Those who went in the hope of such a polemical display were, however, disappointed, for he used the opportunity to state his views on medical reform—and clear views he has on the subject, and you may be sure they were clearly stated, and the statement will serve to keep medical questions before the public.

As a pendant to what I have reported, I may mention another fact illustrating the present aspect of science toward religion. At the Church Congress which has just been held, Professor Flower, of the College of Surgeons, and Mr. Le Gros Clark gave the assembled clergy an account of the most recent scientific investigations and their bearing on questions of faith. They were listened to with much interest and their statements widely reported. Surely after this, and the stand made at the introductions, we shall hear no more the assertion that has often been rashly made, that the profession sympathizes with skepticism.

THE TREATMENT OF SCIENCE BY THE MILITARY METHOD.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: IN THE MEDICAL RECORD of September 29th—prompted, confessedly, by Dr. Shufeldt's article on "The U. S. Medical Service," in the same journal under date of August 25th—Prof. Elliott Coues lets "drive" at the "Great Confederacy of Dunces," rather briskly, and with rifled guns.

We suspect something of the sort all along, but for fear of mistake we are told so in just so many words at the end. From the start the "great Confederacy" gets its share of the cannonading, but throughout it is the "second examination" that makes the thunders of the biggest guns. There is no denying the fact, the second examination gets well pounded.

Doubtless believing that he, like Dr. Shufeldt, has a "good case" and a "working vein"—however the two go together—Prof. Coues sets himself the task of showing that the "examination business" is "dangerous," "dubious," "futile," "superfluous," and "occasionally amusing." Whatever others may see, I, for one, fail to perceive the showing. I am unable to catch even the amusing feature. The picture which Prof. Coues draws of his experience at the "second examination" does not appear to me the least bit amusing, but it does appear to be saturated with "an audacious candor," eclipsing that of Dr. Shufeldt as the streaming radiance of the full moon does the feeble light of the glow-worm. Anyway, we know now just how *he* was examined. Knowing it, and assuming that the members of the Army Board are gentlemen favoring even-handed justice, should we believe that Prof. Coues' examination is a sample of second examinations generally? Such can hardly be possible. If so, who would mind them? Where would be the danger of hurting, of wounding the spirit of those delicate ones "worth the rest of the regiment?" Why, the super-sensitive soul of the fragile Keats could have stood the ordeal easily. Had Lord Brougham's criticism of the "Hours of Idleness" been as light, we would never have had the "English Bards and Scotch Reviewers." Had Dr. Shufeldt been assured of the same sort of an examination, it is reasonable to presume that he would not have indulged in so much of that anxiety which he quite graphically depicts. That he got cast the first time proves the difference.

Basing our inference on Prof. Coues' statements, it is found that the Army Board conducts examinations with varying degrees of rigidity—what the professor would call applying the rules best adapted to individuals. I say this because in one case a medical officer of "enviable reputation, respected by his associates, and faithful in the discharge of his medical and military duties," is "thrown" at an examination admitted to be "fair and just"; while another, with neither "fancy nor ambition for medicine," with his "head full of other things," who "cut off legs, made reports, obeyed orders, always in an automatic and perfunctory way," who "does not expect to be thrown," goes forward and is not thrown. Why, do you ask? The reason is supplied: "The examination was a nullity in my case, and properly so." Yet, strange to say, the subject of this examination tells us that "the report was wisely, justly, and courteously based on what I was." Granting the truth of this for argument's sake, one naturally wishes to know why that other officer, who was "wounded where he lived, in his very marrow," was not given the benefit of a little examinative "nullity," instead of throwing him by means confessedly so fair that they left him "not even the vantage-ground of complaint."

Prof. Coues tells us that in his own case no "forbearance" was shown; that the case "was simply decided on its merits." Admitting this, as one of the "brave boys" I beg leave to say that if no forbearance was shown in his case, then great injustice was shown in the

other, and the injustice lay not with the examination as a system, but with the members of the board.

Let me hurry up to add, however, that there isn't one of us dunces that believes the members of the Army Medical Board capable of inflicting an intentional injustice upon any member of the medical profession. Furthermore, speaking for one, I believe the members of the board *can* find out things "about a candidate that everybody did not know before, excepting his ability to pass an examination under every possible disadvantage." Referring *solely* to medical attainments, and taking Professor Coues' estimate of his own as absolute evidence, I believe everybody in Duncedom—and out of it—will concur that the board in finding him "qualified for promotion was either dazzled by his acquirements as a naturalist, or found it out, as he says, by "rising superior to it." If so, why did not the board apply the "scientific method" in the other cases and "rise superior" to them also? Dr. Shufeldt would probably have been willing—that is, if the thing was to be general, for I do not think he is the kind of man to ask for exceptional treatment.

In sober truth, Professor Coues makes a not altogether flattering showing for the Examining Board of the Army Medical Corps. To be sure, he lays it all on the "system;" but the evidence abstracted from his own statements shows that the board does not always follow the same system; and that, may be, is where the shoe pinches. Sometimes, according to him, the candidate "kicks the system out of court," and sometimes, both board and candidate get rid of the system by "rising superior to it;" and this, in special cases, is termed the "correct," that is, the "scientific method." Now, even a dunce can see that the doing of this requires "discrimination"—just what the board is claimed to have had in Professor Coues' case—and the exercise of discrimination presupposes both discriminative capacity and freedom of action. There isn't, then, so much the matter with the "system" after all, since one of the "correct" methods of applying it is to "kick it out of court."

The power to do this is vested in the board. If the board can do it once, it can do it as often as necessary. Then why not do it every time a good man comes up? Dr. Shufeldt is a good man—that I know personally—he is likewise a scientist of considerable attainments. Why not have given him a "nullity," too, especially as this would have been the "scientific method" as applied to men of his kind?

When boards work under a system which permits them the discrimination of rising superior to it, if needs be, one must expect the "Great Confederacy" to rise to a man and ask, why the medical officer that was "wounded where he lived, in his very marrow," is pronounced the victim of a "cast-iron system, too hard and military to be applicable to the requirements of his case?"

The second examination system may be cast-iron, but as long as it can be treated as a "nullity," can be "kicked out of court, be risen superior to"—while such convenient alternatives are usable what difference does its hardness make? One might add, however, that the alternatives just referred to, although "scientific," and therefore unmilitary, suggest, as applied to the "system," not so much cast-iron as elasticity.

In regard to examinations, everybody admits that there are many bad ones. Are there not also some good ones? It is possible to fluster a highly sensitive nature under "strain and stress," and it is possible to so shape questions as to cause the rejection of perfectly competent candidates. But do boards set out to do this? I think not. Let us suppose a candidate before the board—one of the highly sensitive sort. Let us suppose *him* like one of those described by Professor Coues. "Hundreds of his brother officers," "a thousand soldiers" know him by his work. "Not a clerk in the Surgeon-General's office but knows how that officer stands." Examining boards are supposed to be composed of men of intelligence and information. Army boards certainly are.

What, then, hinders the board from knowing what soldiers and clerks know so well? Go to! it does know.

But even if it do not, and refusing to avail itself of any of the alternatives referred to above, why can it not truly find out a candidate's qualification for promotion and report accordingly, instead of turning him adrift to be consumed by his Greek fire? This cannot always be done in an hour, nor in two hours, but it can be done, nevertheless. Presumptively, the board's object is to get at the facts; the board has been shown to have considerable discriminative power, backed by three powerful alternatives, defying all the cast-iron in any system; is it not fair, then, to suppose that it can take as much time as it chooses? Speaking for one dunce, I believe the language of the board toward such a candidate would be substantially this: "Doctor, hundreds of your brother officers know you, a thousand soldiers know you, the clerks in the Surgeon-General's office know you, and this board thinks it knows you as well as they. We propose fair-dealing. Professor Coues says you know your proficiencies and deficiencies better than we can find out. He says, moreover, that if called to give an account of yourself you will *do it*, fairly and squarely. You are now called to that account; give it fairly and squarely, and you will be treated according to your deserts." This may be cast-iron, but it savors so much of fair play that if the candidate flunked under it, it would be just as well to let him go and fight it out with his Greek fire.

It is not entirely irrelevant to ask, if the second examination is superfluous, why also is not the first? Professor Coues asserts: "Depend upon it, no board is going to find out anything about a candidate that everybody did not know before." Everybody, includes, of course, the faculty of his *alma mater*, supposing his *alma mater* to be one of the real nice, hard school, under whose eye he has been for twenty months, or more, and from whom he has finally obtained credentials of fitness. There is a chance here to chop some logic about competitive examination and survival of the fittest, before the first board, but the same will apply quite as well to the second.

It may be peculiar to a "brave boy" to believe that an examination conducted by a board seriously in quest of the true standing of a candidate is a fair test of fitness, if so, the "brave boy" need not be ashamed of it. It was an Oxford professor, I think, who said that the man who stands up pluckiest under a long and searching examination is the one surest to leave his mark behind him. Rough handling used up Keats, but it invigorated Byron and Webster.

Professor Coues tells us that on his theory Dr. Shufeldt does not belong to the army. "On the contrary, the army belongs to him, and nothing the army can give him is too good for him." That "he never ought to know a 'commanding officer,' nor hear sick-call blow, nor see a patient, nor wear a sword." What I make out of this—dunces are liable to err—is that Dr. Shufeldt, on account of the "spark," having special aptitude for scientific work, and the requisite qualifications to become a great naturalist, should be given "the necessary conditions of environment, and have the rules adapted to the individual." It may be this would foster the scientific spirit and encourage the pursuit of science; but it seems to me it would turn out awkwardly, unless the army is ready for two sets of officers, one to attend to duties, the other to cultivate science. If the medical corps of the army is ready to have placed on its roster certain names whose owners are to follow scientific pursuits exclusively, for the glory and benefit of the army, and the rest of the world, well and good. But add this feature, and eliminate the second examination, and it is likely the scientific side of the medical corps will outgrow the other. Nay, it is fair to say, that those "bad rats," a few of which Professor Coues insists are still to be found in the corps, would cover up many absences from sick-call and much ignorance of commanding officers with the engrossing exactions of ornithology and the like,

and not be any too well supplied with the "inner light" either.

So far as I know, there is no branch of the Government that makes a double provision. As Prof. Coues says, "So long as any man is voluntarily a member of an organization, civil or military, certain regulations and restrictions must be enforced in his case; but the greatest good to the greatest member is likely to come when rules are best adapted to the individual." The first half of this declaration is absolutely true; the other depends upon the character of the organization, and the issues involved. To every compact there are two parties. When a medical man enters the medical corps of the army, he makes a compact with the Government to perform certain duties for a *quid pro quo*. This compact has the same stipulations in each case. One cannot enter and say, "I am the graduate of a medical school, but I have the bent of a naturalist, I shall not go to sick-call." The Army Medical Corps is justly entitled to be proud of the rigor of its initial examination; where is the use in the cases of those intending to be naturalists?

Seriously, though, a compact made should be a compact kept; and Dr. Shufeldt is the sort of man to keep his. I don't believe he would hold his position with the exemptions previously enumerated. I may mistake, but I believe that he is willing to subscribe to the following creed, which I am "brave boy" enough to express openly before any audience, to wit: I believe that the man who writes himself "doctor of medicine" owes his first allegiance to medicine. That it is the bounden duty of the physician to prevent disease, and heal the sick to the utmost of his ability. I believe that the responsibilities resting upon him are so weighty that they leave him little time for other pursuits. I believe that medicine, being concerned with human life, cannot be consistently carried on as a "side show" to any other calling; that medical science is so profound, so wide-reaching, so engrossing, that it demands with tyrannous exactitude all the working hours of the most gifted of its followers. I believe, furthermore, that the soldier—the poor devil who seems to have been forgotten by all parties up to this time—who is, as Shylock says, "fed with the same food, hurt with the same weapons, subject to the same diseases, healed by the same means, warmed and cooled by the same summer and winter as a Christian is," has the inalienable right to the best knowledge which his medical adviser is capable of acquiring. I believe, too, that he has the imprescriptible right to demand that the surgeon who cuts off his leg shall do it not in an "automatic or perfunctory way"—not "with his head full of other things"—but instead, full of medicine and surgery, in which should be felt at all times a "vivid, resistless, and irrepressible interest."

Finally, whether anyone else subscribes to this creed, which may possibly be fortified by a "halter" and a "club," all the same it is *true*, and therefore not likely to be very unscientific.

JOHN GODFREY, M.D.

NEW ORLEANS, LA.

TRANSFUSION OF BLOOD AND INTRAVENOUS INJECTIONS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In your issue for October 20th, an editorial gives a *résumé* of the transfusion of blood and intravenous injections of saline solutions. Very favorable reports as to the value of the latter procedure in post-partum hemorrhage are there given. The only method spoken of is that used by Heyden and described in the following words: "A glass funnel was used connected with a simple gutta-percha tube, ending in a metallic canula, which was made to penetrate the median vein, in which it was tied." This method and apparatus seems so very simple and easy of application that many physicians may try it in suitable cases.

For this reason I wish to record a failure of this

method in my hands and some precautions that may be used to prevent failure in the future.

In August of the present year Mrs. M—, a multipara, was taken in labor at 7 A.M., and at 12.30 M. was delivered, without assistance, of a dead-born child. The child had been dead, I judged, some twenty-four hours. In attempting to deliver the placenta I found it adherent throughout nearly its whole extent. Fearing post-partum hemorrhage I procured hot water, tincture of iodine, and a Davidson's syringe, and then, as there was some flowing already present, I proceeded to detach the placenta.

During this procedure some hemorrhage took place, but was speedily controlled by the iodine injections. My patient, however, was extremely blanched and prostrated. Every effort was made to get up reaction, but at the end of an hour she was evidently growing weaker. Assisted by Dr. Ashmead, I then attempted the injection of a saline solution. We attached a piece of rubber tubing two feet in length to a funnel; in the other end of the rubber tube inserted a piece of glass tubing about the calibre of the median vein. Binding the arm at the elbow I cut down upon the median vein and passed two ligatures around it about one inch apart. The one nearest the hand was tied tightly. The vein was then raised, an incision was made into it, the canula inserted while the saline solution was flowing, and the canula tied in the vein. The operation was not at all difficult and I can see no reason why the operation may not be done by the general practitioner whenever it is indicated. Much to my surprise, however, the solution did not enter the circulation and my patient did not rally. Every effort was made to force the fluid into the veins but without avail. By means of artificial respiration the patient's life was prolonged for about one hour, but with the means at our command none of the saline solution could be made to enter the veins.

The cause of the failure in this case I can only attribute to the absence in the apparatus of any means of giving a forcible injection. Had my rubber tube been six feet long instead of two, thus giving a pressure at the point of delivery of 2.7 pounds to the inch, the liquid might perhaps have entered the vein. Still better would have been a rubber tube with a simple bulb in its course by means of which pressure could be made on the column of fluid by compressing the bulb with the hand. Profiting by the failure in the past, I should make the following suggestions as to the operation for intravenous injections of saline solutions:

First.—A glass reservoir with a cubic capacity of one pint at least. The ordinary glass funnel is the most convenient reservoir that can usually be obtained.

Second.—A rubber tube of two or three feet in length, with a valveless bulb somewhere in its course. The bulb should be without valves because there will be less liability of entangling bubbles of air or foreign particles in the tube. The tube should be large in order that bubbles of air may readily rise through the liquid in the tube. If the calibre of the tube be small air may be forced down in front of the column of liquid into the circulation, instead of rising as it would do in a larger tube.

Third.—The canula should be of glass so that air might not be carried through it unobserved; it should be bent upon itself slightly to facilitate its introduction into the vein; and its delivery-point should of course be of about the size of the calibre of the median vein. This glass canula should be larger above than at its point of delivery, in order that bubbles of air that may enter at its point will rise upward easily.

An apparatus so simple and so inexpensive will be all that is necessary to do a successful transfusion with the saline solution. The cost of such an apparatus is not above a dollar and a half.

Without attention to these details in preparing the apparatus the operation will fail in a certain proportion of cases.

W. E. FOREST, M.D.

CAN MEASLES OCCUR FIVE TIMES IN THE SAME PATIENT WITHIN THREE MONTHS?

TO THE EDITOR OF THE THE MEDICAL RECORD.

SIR: The report of the visiting physicians to the Board of Managers of the New York Infant Asylum, as it appeared in *THE RECORD* last week, one could hardly believe was intended for publication. But, since it has been published, and is endorsed by men of well-known medical reputation, it renders it simply a matter of duty for some one to question such apparently unheard-of statements, namely, that in an epidemic of measles of less than ten weeks' duration about sixty per cent. of the cases were afflicted twice, nearly twenty per cent. three times, and one individual five times. I would simply ask the question, "Can this be possible?" I have carefully looked over well-known authors without finding an intimation that any one ever reported an individual suffering five separate attacks of measles. Ziemssen, after repeating the report made by Dyrsen, Bierbaum, Spies, and Home, of a child who had suffered measles three times within three months, says, "These cases, however, do not preclude the possibility of deception." He further states, "against the frequent and even customary recurrence of measles, especially espoused in recent times by Trojanowsky, we possess the strongest evidence of good authority. I mention only the names of Berndt, Thuissink, Schönlein, Mayr, also Schott and Bortscher, with whose experience my own thoroughly coincides." Even Panam, from his immense number of observations upon people of every age, has not been able to report a single case of a second attack of measles. The experience of Rosenstein testifies "that he has for forty-four years, and Willan that he has for more than twenty years devoted the closest attention to eruptive diseases, without meeting with any one who had had for the second time measles accompanied with fever." This is strong testimony even against second attacks. But if we admit that other major exanthemata can attack an individual a second time, we must admit the same of measles. That a second attack of measles is possible but rare is testified by Gregory, Eberle, Dewees, Squire, Ringer, Bartholow, Hartshorne, Niemeyer, Meigs, and Pepper. We all know how easily an error can and will be copied; when it is indorsed by fourteen respectable physicians it is time we found out whether or no it is an error.

While intending in this communication to call attention to and bring out some testimony respecting the recurrence of measles, I take the opportunity to protest against a statement in the report under consideration, which I think the signers will, on reflection, confess to be unfair, the statement, namely, which they have italicized, "No case of scarlet fever has occurred in the institution." On October 4th, a child died, and Drs. Campbell and Carlyle, by order of the coroner, made an autopsy. They reported that the child had died from scarlet fever and diphtheria. This was the first case of diphtheria discovered in the institution, and there is no doubt whatever it had existed for some time previous. Now the gentlemen who make the statement that no scarlet fever has occurred in the institution had not sufficient opportunity to decide whether or not the case cited was or was not that disease. The child, as above stated, died October 4th; Dr. Warner's daily service commenced October 3d; Dr. Fowler's, October 5th; and Dr. Bradley's on October 10th. I ask these gentlemen, seriously, if it is fair in them to dispute *on hearsay* the opinion of two reputable physicians.

During the Infant Asylum troubles some efforts have been made to create dissension among the doctors; equally with any member of the medical profession I deplore the calamity that has befallen the Asylum; but let us, as medical men, discover what scientific facts there are and leave the fighting to others. Respectfully,

E. F. BRUSH, M.D.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: At the annual meeting of the Board of Managers of the New York Infant Asylum, held in January last, the President, Mr. Clark Bell, was authorized to reorganize the medical department. In the discharge of this delegated authority, Mr. Clark Bell offered places upon the medical staff to Drs. Alonzo Clark, T. Gaillard Thomas, Fordyce Barker, Lewis A. Sayre, Wm. T. Lusk, Wm. M. Polk, Wm. M. Chamberlain, Allan McL. Hamilton, Fred. A. Sturgis, Andrew H. Smith, George F. Shrady, Clinton Wagner, Charles S. Ward, Lewis H. Sayre, Ed. L. Partridge, Cyrus Edson, Thomas E. Satterthwaite, G. M. Hammond, J. W. Wright, Benj. F. Dawson.

All of these gentlemen declined to accept the positions offered them, or, having accepted them, resigned, when they learned of the action taken by the Board of Managers in reference to the former medical committee.

Since the completion of the reorganization of the medical department by Mr. Clark Bell, the following named members of the staff have resigned, viz., Drs. George M. Lefferts, J. H. Ripley, George S. Conant, Paul F. Mundé, Wm. H. Welch.

Since July 1st, the Mount Vernon branch of the asylum has filed 82 death certificates of children with the proper town authorities. The number of children has thereby been reduced from 225 to 143, and the income of the asylum has been diminished by about \$18,000.

The scientific work of the medical staff (as distinguished from its practical work), so far as it has come to my knowledge, is comprised in the original and marvelous contribution upon the subject of measles contained in the report upon the "Epidemics at the New York Infant Asylum," etc., published in your issue for November 3d.

I quote from this report, as follows: "Number of individuals who had measles, 203; of these 124 had measles twice, 248 cases; 34 had measles thrice, 102 cases; 1 five times, 5 cases."

To appreciate fully the scientific value of these statistics, one must bear in mind the following facts, which are found in the report: "The measles appeared early in August." The report was made up on "October 25th." Consequently, all of the above-cited cases of measles and the recurrences must have taken place within a period of three months. But, who vouches for the correctness of these hitherto unheard-of observations? I search the report in vain for an answer. The four physicians who sign the report state that their duties were begun upon September 29th, October 3d, 5th, and 10th, *i.e.*, during the ninth and tenth weeks of the prevalence of the epidemic, and within three weeks of the date at which the report ends. Surely, these gentlemen do not mean to have us believe that all of these cases of measles occurred under their observation during these three weeks? On the other hand, if any of them were observed before September 29th, what right have these gentlemen to publish this as a portion of their "experience?" Why does not that portion of the medical board on duty from "early in August" to "September 29th," make public its statistics?

I trust that the full details of this epidemic, which doubtless will become historic, may be given to the profession. Yours, etc.,

HENRY D. NICOLL, M.D.

7 WEST THIRTY-NINTH STREET, November 6, 1883.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In our communications to the medical press concerning affairs in the New York Infant Asylum, we have directed our attention mainly to what we considered as great mismanagement on the part of the president. Our action concerned physicians generally, and all managing boards of charitable institutions, and we did not wish that it should be diverted from the main issue by professional

scuffles, in the excitement of which attention should be drawn from the main cause of the disturbance.

But in the interests of literary and medical exactness, we are obliged to notice the communication in your issue of November 3d, regarding "The Epidemic at the New York Infant Asylum and the Report of the Medical Board."

The report is so general in its terms that we do not feel quite sure whether the "certain partial statements in the medical press" refer to what we have written; yet we think we may assume this to be the case, since our communications concerning the Asylum have, from the nature of the circumstances, been prominent. We can say without hesitation that we have facts and figures behind all statements made, as well as more facts and more figures to be used if the occasion requires.

The physicians who sign the report of "The Epidemics" give what they term a tabular statement of *our* experience with measles. Yet if we examine the text we shall see that most important medical events are subscribed to by physicians who have seen little of them, and the report is approved by other physicians who have seen less.

Reports from hospitals and public medical institutions are supposed to furnish valuable medical experience for general professional use. It is expected that such experience will have been the fruit of close and careful observation, and go to make up material for reference and medical history. But Dr. Fowler has only been making daily visits since October 5th, Dr. Bradley since October 10th, and Dr. Warner, who was appointed about September 25th, has been making daily visits only since October 3d. The report, however, refers to cases of measles which occurred from the first of August to the last of September, before these gentlemen had commenced their visits. How can the tables then be designated as "*our* experience with that disease." Would they themselves receive such testimony concerning any debateable incidents of disease? As to our proceedings at Mount Vernon, since they are mentioned in the report, we would refer to the *New York Medical Journal* of October 27th for further particulars. We were not members of the medical board, and when we offered our services the epidemic was under full headway.

It was stated that there were 203 cases of measles from August 1st to October 25th, the date of the report; 124 patients had measles twice, 34 had it once, and one patient had measles five times. These are statements of unusual interest, and naturally lead to an examination of the literature concerning recurring attacks of rubeola. Such recurrence has greatly interested those who have studied contagious diseases. Says Dr. Louis Thomas, Professor of the Polyclinic in Leipzig ("*Ziemssen*," vol. ii., p. 42): "Second attacks of measles are, according to the experience of most observers, exceedingly rare, as much so as second attacks of variola, scarlet fever, varicella, etc." Nor can we regard as incontestable all the cases of second attacks which are recorded. Against the frequent and even customary recurrence of measles, especially espoused in recent times by Trojanowsky, we possess the strongest evidence of good authorities. I mention only the names of Berndt, Thuessink, Schönlein, Mayr, also Schott and Bartscher, with whose experience my own thoroughly coincides. Even Panum, from his immense number of observations upon people of every age, has not been able to report a single case of a second attack of measles. The experienced Rosenstein testifies that he has for forty-four years, and Willan, that he has for more than twenty years, directed the closest attention to eruptive diseases without ever meeting with any one who had had for the second time measles accompanied by fever. Dr. Eberle witnessed but one unequivocal example, Rayen mentions three instances, Dr. Hare one, Dr. Condie several, Dr. Downs is doubtful, except where the first attack may have been the rubcola *sine catarrho*, and Guersent and Blache have seen infants with measles twice in the same year. Further

on Louis gives the names of a number of those who believe in a second attack, and basing his further remarks upon this, says that cases of a second attack may be divided into such as appear a long time after the first attack—that is, at least a quarter or half a year, or generally much later, even from twelve to eighteen years afterward—and into such as occur as early as even a few days after the first attack, or, at most, from three to four weeks afterward.” He then gives the names of various authors who report such cases. “Here, if the diagnosis was correct, there is no doubt of a second infection. On the other hand, a subsequent infection in cases of the second sort is less certain, they should rather be regarded as mere relapses, and be estimated in the same way as the well-known relapses of typhoid fever.”

As is evident, the recurrence of measles even once is considered doubtful by many, and we may therefore well apply the words of Mr. Clark Bell, which he used concerning the healthfulness of the Mount Vernon Home in 1882, to the one patient who had measles five times in less than three months, and say that it is “really phenomenal as compared with other institutions.” It would seem most accurate to place this case in the second class of Louis.

The report says: “While there appears to be several sources from which the diseases were introduced to the Asylum, there is no certainty respecting any of them. Until the present time the New York Infant Asylum has been remarkably free from contagious diseases, and they have not spread. In 1882 there was one case of diphtheria and one of röteln. In 1881 there were two cases of diphtheria. In 1880 there was one case of diphtheria. At the Sixty-first Street home, in the same year, there were two cases of diphtheria in January, which were quarantined and promptly recovered. It is said there were also a few cases of variola.”

In 1879 whooping-cough had extended in the town of Mount Vernon, where it had been epidemic about a year. It appeared in an epidemic form in the asylum, and about twenty-five cases of variola also showed themselves there in the same year. We have had scarlet fever and diphtheria at different periods in the different branches of our institution, but they have not prevailed. We have attributed this in a considerable degree to the immediate isolation of even doubtful cases.

Our search for the cause of the recent epidemic led to the following facts, which seemed sufficiently to account for its origin:

Maggie —, a child from Sixty-first Street branch of the asylum, aged one year, ten months, and two days, entered Mount Vernon July 30th in the afternoon. This child was in the first pavilion on the front side of the main building. On August 1st an eruption appeared on the child; it had a temperature of 105°. The child was examined and returned to the ward, where it remained until the next morning, when it was placed in a small room at the rear of the same building, immediately adjoining the sewing-room. This child had diarrhoea, coryza, conjunctival congestion, and bronchitis. On the 11th of August Mamie —, aged two years and six months, in the same end of the ward, had coryza, bronchitis, enterocolitis, and a temperature of 105° to 106°. She was sick in the same ward for twenty-four hours, and then transferred to the infirmary. Emma S— was the third case, and was sent to quarantine August 15th, from the same ward, after which the epidemic began to spread more rapidly.

The report states that the average mortality from measles, according to the best authority, is twelve per cent. In these statistics of measles, based on the mortality among a large number of cases, the inference is evident that those cases of measles are included in which death results from some of the complications which not infrequently attend the disease. There were 203 individuals who had measles at the Home, and of these 48 died—6 died of diphtheria when convalescing from mea-

sles. Forty-eight deaths would give a mortality of 23.05 per cent.; but the mortality of measles depends so much upon hygienic conditions and treatment that it is necessary to compare epidemics which occur under similar circumstances to decide whether the mortality be large or small. If by an average mortality is meant the figures obtained by adding the mortality occurring among a given number of cases, part of which were in a crowded hospital and part in isolated dwellings, and drawing deductions from these, it is evident that any conclusions from such a source would be almost useless. Some statistics concerning the mortality of measles might be given as found in books, but all physicians know that they do not expect to lose their cases of measles when the surroundings are of the most desirable character, whereas in “hospitals and barracks, in a word, in too crowded localities, the prognosis of measles is less favorable.” “The mortality of measles in general is as a rule slight.” Taber instances the epidemic at Schorndorff in 1827-1828, and places the mortality at 1.8 per cent. in 2,100 cases; Gaissler 2.1 per cent.; others at 4.5 per cent., 2.4 per cent., and in the restricted accommodation of the Children's Hospital at Stockholm of 131 cases 36 per cent. died.

The Home at Mount Vernon is finely situated on an elevated ridge which slopes east and west, depressing southward. It has a subsoil of gravel and has natural drainage into a running brook. There is a large main building, an old building near, and five cottages, besides a “Sanitarium.” It was not a hospital until made so by the epidemic. Whether the mortality was large or not under these circumstances we leave to further investigation; the fact still remains that the true method of managing epidemics is, if possible, to prevent their development.

We have only considered a few points in the report on “The Epidemics at the New York Infant Asylum,” and we cannot intrude too much upon the space of THE RECORD. We believe it is in the interest of physicians to consider whether the questions now pending concerning the New York Infant Asylum do not interest them closely, particularly those who are connected with charitable institutions.

E. A. GOODRIDGE, M.D.

WHY MUST DISTINGUISHED MEN ACCEPT SMALL FEES?

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR: In a letter to THE RECORD for October 20th, Dr. E. C. Wendt has criticised the status of the medical profession of Chicago in such a way as to suggest that he is a close observer, for, to our shame be it said, the doctor has struck the key-note of the chief obstacle to professional advancement in this city. There are men of the highest eminence in this city who are in the habit of charging the nominal fee of a dollar for office consultations of all descriptions. Prescriptions for gonorrhoea, syphilis, and everything else, are scratched off indiscriminately by these mentors (?) for a dollar apiece, and set afloat to bob up occasionally as a grim accusation against some of us poor devils whose consciences are sufficiently callous (or better, who have sufficient self-respect) to enable us to charge ten dollars for a prescription for gonorrhoea. There are men in this city who will give ether or chloroform for a fee of two dollars; men too, who occupy good positions. It is not pleasant to be informed that “Prof. So and So only charged me such a fee,” etc. Many physicians make night calls for a couple of dollars. Now, under such circumstances, what is to be done by those who must practise for bread and butter? They must either work for nominal fees, or go to the wall. Not very pleasant, is it? But it is true. Probably the worst ele-

ment of all is the average German physician, who works for the most trivial fees as a rule. Not that I would slur our German *confrères*, but I would most emphatically remind them that their profession has more claims upon them than their nationality. They should not do American practice for German fees. Why they have imported the German fee-bill it would be difficult to say, but practically, that is what they have done in this city, at least. Dr. Wendt's suggestion, that the "doctors charge more," is a good one, but I fear he can never make the "pigs in the clover-patch" see it. Verily, between high-toned (?) and low-priced "professors" (save the mark), and free clinics and dispensaries, the young man with a "small, but growing (?) practice" has a hard road to hoe, and must make gynecological examinations, and treat stricture of the urethra and piles at two dollars the sitting, or purchase Tanner's secret, and learn to live on air and professional "ethics."

ONE OF THOSE

"WITH THE SMALL BUT GROWING, ETC."

SOME OF THE MEDICAL FATHERS IN NEW YORK.—As an item bearing on the longevity of medical men, it is gratifying to look over a list of medical worthies in this city who have reached their "three score years and ten." The majority are in good health, and not a few are actively engaged in professional pursuits. We append their respective ages as computed from the "Biographic Dictionary of Physicians." Willard Parker, 83; A. C. Post, 77; J. G. Adams, 76; William Detmold, 75; S. G. Hubbard, 75; Isaac E. Taylor, 71; Austin Flint, Sr., 71; Frank H. Hamilton, 70; and J. Martin Sims, 70.

DEAFNESS AMONG SCHOOL CHILDREN.—A second edition of "Causes of Deafness among School Children and its Influence on Education, with Remarks on the Instruction of Pupils with Impaired Hearing and on Aural Hygiene in the Schools," by Samuel Sexton, M.D., has been issued by the Bureau of Education, Washington.

DR. PAUL F. MUNDE has resigned from the New York Infant Asylum.

TRANSACTIONS OF THE MEDICAL SOCIETY OF GEORGIA.—This Society was particularly fortunate, at its session of 1883, in the number and diversity of valuable articles presented for consideration. Many of them exhibit a considerable degree of thought and research on the part of our Southern friends; and all show that the "Empire State of the South" is not behind in the advancement of medical science. The official "Transactions" form a handsome octavo volume which merits more consideration than mere shelf-room. The Society has offered a prize of \$50 to Georgia physicians for the best essay presented before its next annual meeting.

TRANSACTIONS OF THE STATE MEDICAL SOCIETY OF INDIANA.—The present volume of "Transactions of the State Medical Society of Indiana" contains a number of interesting papers presented at the meeting in May. Sponge-grafting, bacteria, typhoid fever, Bright's disease, injuries to the head, and laceration of the cervix are a few of the variety of subjects ably discussed. Probably the most entertaining is a communication from Dr. Lopp, of Columbus, detailing some of the blunders of quacks in Indiana. In order to prevent a continuance of such blunders the Committee on Legislation recommends State examinations of all who wish to practise medicine.

THE DEATH OF M. THUILLIER.—It is not generally known that M. Thuillier, the young physician who died while serving on the cholera commission in Egypt, had already made some original and valuable discoveries in preventive medicine. It was he who discovered some time ago the microbe which causes the *rouget* or typhus in swine. At the Académie de Médecine M. Bouley recently read a letter from M. Maucuer, a veterinarian at Ballène, to the effect that by cultivating this microbe a vaccine had been found which had proved perfectly efficacious in protecting the swine from typhus.

PROPAGATING CANCER BY SEXUAL INTERCOURSE.—Dr. T. Gaillard Thomas says in answer to a question by one of his clinical class: There is undoubtedly great danger of propagating cancer by sexual intercourse, and repeated instances of cancer of the penis being contracted in this way are on record. The slightest abrasion of the penis may be sufficient for the absorption of virus from the malignant growth, and the husbands of women suffering from cancer of the uterus should, therefore, always be warned against intercourse with their wives. This, as you see, is a matter of very considerable importance, and I am glad that the point has been suggested.—*Medical Review.*

THE HYPODERMIC SYRINGE.—Dr. Frank D. Stevens, of Lynn, Mass., writes:—"I have never had any trouble with my hypodermic syringe since I have adopted the method of adjusting a rubber tip to the lower extremity of the syringe. For this purpose I use the upper two-thirds of a common rubber tip such as is found upon an ordinary medicine dropper. In this way the syringe is kept absolutely tight, and if care is taken to leave a little of the solution in the syringe after using, the packing will remain moist and pliable for a long time."

A FREQUENT MISTAKE.—A writer points out the "verbal pitfall" into which many fall, of speaking of malaria as though it were a disease instead of a cause of disease.

THE DIGESTIBILITY OF LOBSTERS.—Dr. Norton Folsom writes (*Boston Medical and Surgical Journal*) that while in service at the Taunton Lunatic Hospital he had charge of the diet of about four hundred and fifty patients. During the plentiful season, all patients not acutely sick had well-boiled plain lobster once a week. Not a single instance of digestion disturbance occurred in consequence. Dr. Folsom thinks that lobsters, if fresh and well boiled, are a wholesome food for all without a special idiosyncrasy against them.

TYPHOID FEVER IN NEW YORK CITY.

By FRANCIS DELAFIELD, M.D.,

PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE, NEW YORK.

TYPHOID fever is a disease which seems to be fairly endemic in New York, although it is much more prevalent in some years than in others. If we turn to the records of the Board of Health, we find that the mortality from typhoid fever, since the year 1854, has been as follows:

Year.	Deaths.	Year.	Deaths.	Year.	Deaths.
1854.....	136	1864.....	661	1874.....	275
1855.....	139	1865.....	513	1875.....	348
1856.....	133	1866.....	514	1876.....	283
1857.....	141	1867.....	345	1877.....	275
1858.....	176	1868.....	326	1878.....	245
1859.....	206	1869.....	378	1879.....	178
1860.....	212	1870.....	422	1880.....	241
1861.....	234	1871.....	239	1881.....	446
1862.....	494	1872.....	364	1882.....	362
1863.....	531	1873.....	295	1883 (to Oct. 1st)	274

The disease was most prevalent in the years 1863, 1864, and 1865, the same years during which typhus fever existed as an epidemic in New York.

The time of year during which the disease prevails can be seen from the following table of

CASES REPORTED AT THE SANITARY BUREAU.

	1878.	1879.	1880.	1881.	1882.	1883.	Total.
January.....	43	37	22	42	46	47	237
February.....	27	21	31	23	30	25	157
March.....	16	19	33	58	25	48	199
April.....	29	21	21	82	22	26	201
May.....	24	23	37	50	25	29	188
June.....	25	27	22	31	20	28	153
July.....	36	24	39	63	40	93	293
August.....	98	53	46	115	96	244	652
September.....	89	74	63	132	117	356	833
October.....	105	62	64	138	147	...	...
November.....	62	34	73	129	68	...	...
December.....	44	37	57	102	50	...	...
Total.....	598	432	508	965	686	...	...

It appears that while cases of the disease occur in every month, yet that August, September, and October are characterized by a large increase in the number of patients. In order to obtain a still more accurate idea of the prevalence of the disease, I have had prepared some statistics of the cases which have occurred in the hospitals during the years 1877 to October 1, 1883:

HOSPITALS.	1877.		1878.		1879.		1880.		1881.		1882.		1883 to Oct. 1.		Mortality, per cent.
	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.	
Riverside.....	8	4	20	8	12	4	9	1	62	6	11	1	13	4	20.7
Bellevue.....	49	17	31	11	11	4	22	10	52	16	105	28	41	15	32.4
Roosevelt.....	16	4	11	3	13	1	14	0	27	11	54	17	12	6	36.8
New York.....	12	2	7	2	12	2	19	7	27	5	11	3	19	2	21.4
St. Luke's.....	5	1	8	2	7	2	8	3	19	3	29	9	9	2	25.8
St. Vincent's.....	14	1	8	2	6	0	9	4	20	6	14	2	17	8	25.9
St. Francis.....	20	7	24	4	17	2	18	6	56	17	71	11	57	9	21.3
Mt. Sinai.....	11	1	15	2	36	8	11	2	56	9	18	4	22	3	17.1
Total.....	135	37	124	34	114	23	110	33	319	73	313	75	190	51	
Percentage of mortality.....	27.4		27.4		20.1		30.0		22.7		23.9		26.8		

Altogether 1,305 cases.

From this table it will be seen that the disease prevailed during the years 1877, 1878, 1879, and 1880 to a moderate extent, and with a varying degree of mortality, the year 1880 being marked by the highest percentage of mortality. In 1881, 1882, and 1883, although the whole number of cases was greater, yet the mortality was not very great.

In determining the age of the patients from the hospital records, it must be remembered that the regular population of these hospitals consists of adults, children being admitted only in small numbers. Allowing for this circumstance, the relative frequency of the disease at different ages has been as follows:

5 to 10.....	49	30 to 40.....	186	60 to 70.....	8
10 to 20.....	336	40 to 50.....	77	70.....	4
20 to 30.....	604	50 to 60.....	16		

Etiology.—The city of New York is not a favorable field for studying the etiology of this disease. The entire city has the same water-supply, and a large part of it the same system of sewerage. A considerable number of the cases originate outside of the city, and are taken sick here. The determination of the local causes in the city will probably be facilitated by the investigations which are now being carried on by the Board of Health.

LESIONS.

Intestinal lesions.—The regular lesions of the solitary and agminated glands of the ileum were in most cases fairly developed. Some of the patients died while these glands were only swollen, some while the sloughs were adherent, some after the ulcers were completely cleaned off. The changes were, however, even in the worst cases confined to the glands, with sometimes a little infiltration of the surrounding tissue. The large infiltrations of the intestinal wall, which occur in some epidemics, have not come under my observation. But in a considerable number of the fatal cases the intestinal lesion was inconsiderable; only a few swollen agminated glands with partial ulceration.

Perforation of the intestine with peritonitis has not been of common occurrence. In one case the perforation was through an ulcer in the wall of the vermiform appendix.

In the colon, enlargement and ulceration of the solitary glands was found only in five cases.

The mesenteric glands were swollen in all the cases, sometimes more sometimes less, generally corresponding to the degree of the intestinal lesion. When the glands were very much swollen there was sometimes a little fibrine on the peritoneum over them; in one case this had extended to a general peritonitis. In two cases these glands had suppurated and produced local peritonitis.

The spleen was soft in all the cases, usually enlarged, but sometimes of normal size or even small. In one case, a boy eight years of age, the spleen was ruptured with large extravasation of blood into the peritoneal cavity.

Croupous inflammation of the colon was present in one case. The lower two-thirds of the colon were coated with a uniform layer of fibrine.

General peritonitis, without perforation of the intestine, or suppuration of the mesenteric glands, was seen in one case.

The parotid glands have not been inflamed in any of the cases which I have seen.

The liver in many of the cases was enlarged, with some parenchymatous degeneration of the hepatic cells.

The kidneys in most of the cases were the seat of more or less severe parenchymatous nephritis; but these lesions of the kidney did not always produce changes in the urine during the life of the patient.

the dependent portion of the lungs was much more marked, and the lung-tissue was at the same time dense and unaërated. A few pus-cells, a little fibrine and granular matter were often to be found in the air-vesicles of the congested portions of lung.

In two cases the posterior portions of the lungs were

FIG. 1.

The heart, although sometimes soft and flabby with degeneration of the muscular fibres; was yet in many cases firm, strongly contracted, and with perfectly normal muscle.

The lungs have been diseased to some extent in

not only congested, but there were also irregular areas of red hepatization.

In three cases the lungs exhibited the lesions of intense general bronchitis.

In one of these cases the larger bronchi were congested

FIG. 2.

many cases. Moderate degrees of bronchitis with congestion of the larger bronchi and an increased production of mucus were often seen.

Some degree of congestion and cedema was present in nearly all the lungs, involving regularly their most dependent portions. Less frequently the congestion of

and coated with mucus. The smaller bronchi were full of pus, their walls were thickened. Throughout both lungs were numerous circumscribed portions of lung, from the size of a walnut to that of a pigeon's egg, which were dense, smooth, unaërated, of a deep, livid color—collapsed lung.

In the second case the lungs were small and congested. The larger bronchi were congested and coated with mucus; the smaller bronchi were full of pus, their walls were thickened and infiltrated with cells, and around them were small zones of intense congestion or of red hepatization.

In the third case the larger bronchi were congested, the smaller bronchi had their walls thickened and infiltrated with cells. Around these small bronchi were small zones of white hepatization, and around these peri-bronchitic zones larger areas of red hepatization.

Lobar pneumonia was found in two patients. In one nearly the whole of both lungs was consolidated, in the other only a single lobe of one lung.

In the brain and its membranes I have found no lesions, except old ones not belonging to the disease.

The voluntary muscles have presented their characteristic granular and waxy degeneration in a moderate number of the more severe cases; in many other cases no change in the muscles was found.

It is evident, therefore, that the anatomical type of the disease, as it has prevailed in New York during the past eight years, has not been a severe one. Neither the characteristic nor the accessory lesions have been more than fairly marked.

In speaking of the lesions of the disease I have drawn from a larger number of cases than that employed for the study of the symptoms, for many of the hospital cases die with hardly any history.

Symptoms.—To illustrate the character of the symptoms I have used the records of 102 cases, all occurring during the past five years. A larger number of cases could have been collated, but I have preferred to confine myself to this number of cases, all of which were well-marked examples of the disease.

Prodromata.—A distinct history of a prodromic period was obtained only in 18 cases. In all the conditions were much the same: languor, headache, indisposition to mental or bodily exertion, loss of appetite, constipation or diarrhoea, irregular chilliness, sometimes bronchitis. The duration of this period varied from four days to five weeks.

Invasion.—The character of the invasion was ascertained in 83 cases. In 37 cases the patients noticed a chill at the very commencement of the disease. This chill was sometimes described as mild, sometimes as severe; it occurred only once, or was repeated for several days. The chill was always followed by a febrile movement, often accompanied with headache, sometimes with vomiting, sometimes with nose-bleed, and in 19 cases with diarrhoea.

In 25 cases the first symptom was diarrhoea, accompanied with fever, sometimes with headache, sometimes with nose-bleed. There were, therefore, altogether 44 cases in which diarrhoea was one of the first symptoms, and in 3 of these blood was mixed with the passages during the first few days.

In 15 cases headache and fever, sometimes with nose-bleed, marked the onset of the disease.

In 6 cases a marked bronchitis, with cough, expectoration, and physical signs, was the most prominent feature during the first week.

Altogether nose-bleed was mentioned by 14 of the patients. Pain in the right iliac fossa or abdomen was often complained of.

In the other cases it could not be ascertained exactly when or how the disease began. This seemed to be due sometimes to want of intelligence on the part of the patient, sometimes to the existence of accidental conditions to which attention was directed rather than to the real disease.

Temperature.—Complete records of the temperature embracing the first days of the disease were not obtained in any cases. Many of the patients did not come under observation until the disease had existed for some time, in others the temperature was not taken until the disease became very manifest.

The schematic curve for the regular four weeks of typhoid fever is that given in Fig. 1.

We may compare with this some of the temperature charts obtained from different patients: Fig. 2 is from a patient who came into the hospital on the third day of the disease and became convalescent on the thirtieth day. For two days he had creeping chills, general malaise, pharyngitis, and came into the hospital on the third day and went to bed. On the ninth day moderate diarrhoea. On the fourteenth day hemorrhage from the bowels attended with a fall of temperature to 97° . On the sixteenth day two more hemorrhages were followed by a fall of temperature to 98.6° .

FIG. 3.

The temperature curve in Fig. 3 was taken from a regular case without complications. All the symptoms were well marked and the convalescence was uninterupted.

A study of all the temperature curves shows that we must not expect too close a correspondence with the schematic curve.

During the first week the temperature regularly rises, but there is a great difference in the rapidity of the rise and the number of days required for it to reach its maximum. In hospital patients the transfer to the hospital seems often to produce a temporary rise of temperature. In some patients morning chills followed by afternoon fever may be repeated several times during the first week. There may be sudden falls of temperature for six, four, or twenty-four hours during the first week.

In the second week the temperature approaches the continuous type with moderate morning remissions; but sometimes the morning remissions are very marked. Sometimes the morning temperature is the highest; sometimes the temperature falls permanently to the normal by the fifteenth day; or after beginning to fall by morning remissions the temperature may go up again and continue to the end of the third, fourth, or fifth week; or, in fatal cases, the temperature may reach its highest point just before death, or fall to 101° or 100° .

In the third week the temperature may continue as in the second, or it may fall more or less regularly with normal remissions.

In the fourth week the temperature usually falls by morning remissions, but this fall is often interrupted and irregular. The morning remissions may be followed by sweating. Or, after beginning to fall, the temperature will rise again and continue till the end of the fifth, sixth, seventh, or eighth week.

In the cases without relapses convalescence was most common at the end of the fourth week; it was not uncommon in the third week, and it was sometimes delayed till the end of the fifth, sixth, seventh, or eighth weeks. When there were relapses the disease might be still further prolonged.

The height of the temperature was usually in proportion to the disease, but to this rule there were many exceptions: mild cases with high temperatures, and severe cases with low temperatures. There was also a good deal of difference in the cases as to their ability to bear the temperature. Some patients would be much more affected by a temperature of 102° than others, by a temperature of 105° .

The pulse usually followed the curve of temperature, becoming more rapid as the temperature was higher. During the first week of the disease the pulse was strong, from 80 to 100. In the second and third weeks it was more rapid and feeble, often dicrotic. As a rule the pulse became more rapid as it was more feeble, but sometimes it was both feeble and slow. Generally speaking, a rapid pulse was an unfavorable symptom, but sometimes the pulse continued rapid while the temperature was falling and convalescence approaching. In the cases that died with a lower temperature, the pulse was feeble and rapid. Some cases ran their entire course with a pulse of from 60 to 80; when this was joined with marked cerebral symptoms, the cases closely resembled cerebro-spinal meningitis.

The appearance of the patients was characteristic. A dull, apathetic expression, the skin of the face dusky-colored, the cheeks often flushed, the mind dull and sluggish—all these conditions were well marked. In only one case were these symptoms notably absent, in a patient who for the first two weeks had a bright face and an active mind.

The tongue was usually at first coated with a thick white fur, afterward dry and brown; sometimes it remained clean, but became gradually dry, glazed, and fissured.

Nose-bleed occurred in many of the cases, not only in the invasion of the disease, but later in its course. In only one case did it reach such a degree as to become alarming.

Headache and sleeplessness were most common in the

prodromic period and during the first week of the disease.

Delirium of an active and well-marked type was present in forty-one cases; it marked a severe form of the disease. Lower degrees of delirium, occurring especially at night, were much more common.

Complete unconsciousness was usually a fatal symptom, although apathy verging on stupor was seen in many of the cases which recovered.

Vomiting not only marked the invasion of the disease, but sometimes continued throughout its course, and was then a most annoying symptom, interfering with the administration of food and medicine.

Diarrhœa was present in 82 cases, and in 44 of these it began during the first days of the disease. In 11 cases, after beginning during the first days of the disease, it only lasted a few days and then stopped. In 51 cases it lasted through nearly the whole of the disease, and in 20 cases it only lasted for a few days in the second week.

Constipation throughout the whole course of the disease was observed in eighteen cases. It was almost the rule to have some degree of constipation during convalescence.

The eruption is recorded as being fairly marked in forty-four cases, but in only a few of these was it very abundant. It seemed to be more constant in the cases which have occurred during the last year. It was usually seen during the second week, sometimes appearing in successive crops, especially with the relapses.

Tympanitis to a greater or less degree was often present; it was most marked in the patients who were constipated.

Pain over the abdomen certainly existed in a number of the cases, but the records on this point were somewhat uncertain.

The urine contained albumen in twenty-three cases; it was never present in large amount. Casts were found in the same cases in small numbers. It contained blood in two cases.

Hemorrhage from the bowels occurred in twenty-three cases, and in six of these cases it proved fatal. In three cases there was moderate bleeding during the first weeks of the disease. In the other cases it occurred at the following periods: On the eighth day, one case; on the tenth day, one case; on the eleventh day, one case; on the twelfth day, one case; on the thirteenth day, three cases. In the second week, three cases; in the third week, two cases; in the fourth week, four cases; in the fifth week, one case; in the sixth week, one case; in the seventh week, one case. Throughout the disease, one case. Most of these hemorrhages were considerable in amount and repeated several times.

Hemorrhages in the skin were only seen in one case.

Complications.—A pustular eruption of the skin, the pustules situated all over the body and reaching the dimensions of small abscesses, was seen in three cases.

Suppurative inflammation of the middle ear, with discharge of pus, occurred in five cases.

Croupous pharyngitis existed in one case during the first week of the disease.

Bronchitis of a severe type, or broncho-pneumonia, existed in twenty-four cases, and in sixteen of these cases occurred early in the disease. In many other cases slight forms of bronchitis were present. When bronchitis occurred early in the disease its symptoms were sometimes so marked as to obscure those of the typhoid fever. Only three of the cases of bronchitis proved fatal.

Lobar pneumonia occurred in two cases, and both of these caused the death of the patient.

Repeated attacks of feeble heart-action, the radial pulse becoming imperceptible, were observed in one patient. She finally died in such an attack.

Peritonitis occurred in only four cases. In two of these it was due to perforation of an ulcer of the ileum, in one to perforation of the appendix vermiformis, and

in one to inflammation of the mesenteric glands. In all the four cases the peritonitis was fatal.

Thrombosis of the femoral vein occurred in one case.

Dysentery was observed in five cases. It was developed during convalescence, in the fifth, sixth, and eighth weeks. In one of the cases it proved fatal, and was then found to be of the croupous variety.

The course of the disease.—In the cases which recovered, excluding the cases with relapses, the duration could be ascertained in sixty-one. In these convalescence commenced at the following periods: On the sixteenth day, one case; on the eighteenth day, four cases; at the end of the third week, six cases; at the end of the fourth week, nineteen cases; at the end of the fifth week, twelve cases; at the end of the sixth week, four cases; at the end of the seventh week, four cases; at the end of the eighth week, one case; at the end of the ninth week, nine cases; at the end of the tenth week, one case. In the cases which lasted longer than three weeks there were often periods of from twelve to twenty-four hours during which the temperature fell, and it seemed as if convalescence was commencing; but then the temperature rose again and the disease went on.

Relapses were observed only in seven cases, all of which recovered. The relapses occurred as follows: In the fourth week cessation of all the symptoms for ten days, then a relapse of fourteen days, then convalescence. In the fourth week cessation of all the symptoms for five days, then a relapse for ten days, then another cessation for fourteen days, then a second relapse for eight days, and then convalescence. In the fourth week cessation of the symptoms for seven days, then a relapse for two weeks. In the sixth week a cessation of the symptoms for four days, then a relapse for seven days. In the sixth week a cessation for thirteen days, then a relapse for two weeks. In the sixth week a cessation for thirteen days, then a relapse for one week. In the tenth week a cessation for five days, then a relapse for one week. All of these cases were very seriously ill, and yet recovered in spite of the long continuance of the disease.

The thirty-four fatal cases died at the following periods: On the eighth day, two cases; on the tenth day, one case; on the eleventh day, one case; on the twelfth day, one case; on the thirteenth day, five cases; on the fourteenth day, one case; on the sixteenth day, two cases; on the seventeenth day, one case; on the eighteenth day, one case; on the nineteenth day, one case; at the end of three weeks, two cases; at the end of four weeks, four cases; at the end of five weeks, four cases; at the end of six weeks, five cases; at the end of ten weeks, one case.

The manner of death was as follows: In fifteen cases the patients seemed to die from the direct effect of the disease. In most of these cases the temperature was high and the pulse rapid and feeble. Death took place from the eighth day to the end of the sixth week. In three cases the immediate cause of death appeared to be severe broncho-pneumonia, death taking place on the eighth day, at the end of three weeks, and at the end of five weeks. In six cases death followed soon after large hemorrhages from the bowels; two cases on the thirteenth day, one on the fourteenth day, one on the thirty-second day, and two at the end of six weeks. Four cases died with acute general peritonitis. In three of these the peritonitis was due to perforation and proved fatal on the eleventh, thirteenth, and twenty-eighth days. In one case it was due to inflammation of the mesenteric glands, the patient dying at the end of six weeks.

One case died of dysentery at the end of ten weeks; one case died of syncope at the end of four weeks; one case died in collapse, with a temperature of 95° in the rectum after sponging with ice-water; one case died from rupture of the spleen at the end of four weeks; two cases died with lobar pneumonia, one on the eighth and one on the eleventh day.

It may be instructive to recite in detail a few of the irregular cases.

CASE I.—A male, aged twenty-four; on August 18th and 19th had diarrhœa, but did not feel ill. On August 21st he was seized, after dinner, with an attack of vertigo and partial unconsciousness. Similar attacks have been repeated and have been accompanied by constant headache, pain in the back, and a general tired, weak feeling. He was admitted to the hospital on August 25th. He then had the appearance of a patient suffering from typhoid fever; high temperature, tongue brown and dry, face flushed, mind dull. On August 29th the eruption appeared on the abdomen and chest. On August 31st he passed blood and mucus from the bowels; before this there was no diarrhœa. On September 1st he was a little delirious at night. On September 4th he felt so well that he wished to sit up. On September 5th he became delirious, his pulse was rapid and feeble, his tongue again became brown and dry, and on September 6th he died. The table shows the temperature and pulse.

FIG. 4.

In the intestine only four of the agminated glands were found swollen, but not ulcerated. The mesenteric glands were swollen. In the left ventricle of the heart was an old ante-mortem clot the size of a chestnut. In the enlarged spleen were three infarctions.

This was a case in which, from the clinical history, one would have expected to find the intestinal lesions developed in proportion to the severity of the constitutional symptoms.

CASE II. is a contrast to the preceding one. A man, twenty-two years of age, began on August 1st to have diarrhœa. Some of the passages were fecal, some were streaked with blood. He had no other symptoms and did not feel ill. On August 6th, for the first time, he remained in bed; his pulse was 100, his temperature 99° ; he had pain in the abdomen and diarrhœa. On August 7th, pulse 100 to 110; temperature 100° to $101\frac{1}{2}^{\circ}$; tongue dry; the diarrhœa has stopped. On August 10th, pulse 100 to 110; temperature 101° to 102° . August 11th, large passages of blood from the bowels; pulse 110 to 125; temperature 101° to 102° ; he became delirious. August 12th, died.

For nearly the whole length of the ileum the solitary and agminated glands were very much swollen and ulcerated. In the colon for its entire length the solitary glands were swollen and ulcerated. In the stomach were a number of small round ulcers. In this case the characteristic lesions were developed to an unusual degree, and yet the fever and other constitutional symptoms were not at all marked.

CASE III.—A man, aged twenty-five; said that he had not been feeling well for two weeks; that on October 6th,

after working in an ice-house, he caught cold and had cough and headache, fever and sweating. October 10th his face was flushed, his tongue dry and brown, his bowels loose, his mind dull and apathetic; his urine contained a little albumen. There was a good deal of dyspnoea, and coarse and subcrepitant râles could be heard over the whole of both lungs. The evidences of bronchitis continued. On October 13th he became delirious; on October 17th he had a number of large bloody passages from the bowels, his skin became cold and livid, his pulse rapid and very feeble, and he died on October 18th. The temperature and pulse can be seen in the table.

FIG. 5.

After death the lungs exhibited the lesions of intense general bronchitis. In the small intestine the solitary and agminated glands were very much swollen, and formed large ulcers from which the sloughs had cleaned off.

In this case the bronchitis seemed sufficient to account for all the patient's symptoms until he began to have the hemorrhages from the bowels.

CASE IV.—A man, aged forty-five; said that he had not been feeling well for several weeks. On November 25th he felt worse, but went on a journey and returned on November 28th. On November 29th, in the evening, he had a severe chill and remained in bed the next day. His bowels had been constipated, and on this day were acted on by medicine. On November 30th his temperature was taken for the first time and found to be 105°. From this time till December 5th the patient was in bed with a temperature of from 101° to 102°. His tongue was clean and moist, his mind clear, his bowels constipated; no eruptions, but several attacks of nose-bleed. On December 5th he began to cough and expectorate muco-purulent matter. On December 8th there were dulness on percussion and loss of breathing over the lower part of both lungs. On December 9th, pulse, 114 to 140; temperature, 103° to 99½°; respiration, 34 to 40. On December 10th, pulse, 114; temperature, 102°. On December 11th, pulse, 114 to 120; temperature, 102½° to 102°. The patient now began to look worse, although his tongue was still clean and his mind clear. The constipation had continued, and now tympanites was developed. December 12th, pulse, 120; temperature, 102° to 101½°. December 13th, pulse, 120 to 128; temperature, 100½°. December 14th, pulse, 120 to 128; temperature, 100° to 101°. The tympanites continued, became worse, and distressed the patient extremely. The bowels only moved with medicine. The patient died with feeble heart on December 15th.

At the autopsy the bronchi were found congested and coated with muco-pus; both lower lobes of the lungs were congested and unaerated. In the small intestine a number of the agminated glands were changed into clean, smooth ulcers extending down to the muscular coat.

This case was as obscure as need be during the patient's life.

Treatment.—A fair idea of the manner in which typhoid fever is treated in New York may be gathered from the routine of the different hospitals.

In the New York Hospital many patients are simply put on a milk diet, with the addition of a moderate amount of whiskey, and no other treatment is used. Peptonized milk instead of ordinary milk is thought to be of service. For high temperatures the body is sponged with equal parts of alcohol and water, and sometimes the fluid extract of eucalyptus is given in fifteen-minim doses. Quinine is not much used. Tympanites is treated with turpentine internally, and in stupes over the abdomen. Opium is given when there is hemorrhage from the bowels or excessive diarrhoea.

At St. Luke's Hospital the treatment is the same, except that quinine is sometimes employed to reduce the temperature, and ergotine hypodermically for intestinal hemorrhage. Either opium or chloral are used to control restlessness and sleeplessness.

At St. Francis' Hospital, if the cases are seen early in the disease, large doses of calomel are given, with the idea of aborting the disease. Quinine in large doses is given to most of the patients. The salicylate of soda or the benzoate of soda are given by some of the physicians throughout the disease. Cold water in any form, to reduce the temperature, is but very little used. A solution of the acetate of alumina is given to nearly all the patients to prevent or control the diarrhoea.

At St. Vincent's Hospital quinine in doses of two grains every two hours is given to control the temperature. Cold water is not employed. Opium is used with diarrhoea and intestinal hemorrhage.

At the Mount Sinai Hospital quinine in large doses is given to nearly all the patients. Cold water is not much used, but sometimes the patients are sponged off.

At Bellevue Hospital the treatment varies in the different divisions.

In one division the peptonized milk is much used. Quinine, in large doses, is given when the temperature reaches 103°, and sponging is also sometimes used. Opium, the bromides, and cold to the head are used for the restlessness.

In another division quinine in moderate doses is given to most of the patients. For temperatures over 103° sponging with cold water or the Kibbee cot and sprinkling with cold water are used. Opium is given when needed.

In another division carbolic acid gtt. j. and tincture iodine gtt. ij. every two hours are given early in the disease. Quinine in ten-grain doses every half hour is given to reduce the temperature. Sponging with cold water is sometimes used. Opium is employed for severe diarrhoea.

In another division occasional sponging, and whiskey and opium when required are the only treatment.

At the Roosevelt Hospital full bathing has been tried in many cases but now cold sponging is more used. Bismuth and pepsin are given to many of the patients.

In all the hospitals milk, either simple or peptonized, is the regular diet of the patients.

THE DOCTRINE OF SPONTANEOUS GENERATION REVIVED.—At a recent meeting of the Academy of Medicine of Paris, M. Bouchardat maintained that in the genesis of phthisis, certain portions of the lung were not expanded sufficiently, there occurred local stasis, and at these points the lymph-corpuscles are metamorphosed into the bacilli of tuberculosis. This is a revival of the doctrine of heterogenesis upheld by Bastian. M. Bouchardat does not believe in the contagiousness of phthisis.

FUNCTIONAL DISEASES OF THE HEART.

BY E. P. HURD, M.D.,

NEWBURYPORT, MASS.

(Continued from page 425.)

PART II.—PATHOLOGICAL.

FUNCTIONAL diseases are said to coexist with integrity of the structure whose physiological action is disturbed. While it is admitted that there may be morbid alterations of texture, these are too subtle to be detected by the senses of the observer. The stomach of the dyspeptic has been examined after death, and blood-vessels and peptic glands have been pronounced sound. The arhythmic heart, whose disorderly action long gave so much trouble, has been found normal at the autopsy. Facts of this kind are doubtless sufficiently abundant to justify the distinction which has been made between functional and organic diseases. At the same time it must be understood that the distinction is only a relative one. It is from the nature of things impossible that disease of any kind can exist without impairment of structure. If the function is deranged, it is because the interstitial movements of waste and repair which are going on in the organ are disturbed, for the function of a part is in the closest correlation with its nutrition. To say that there is disturbance of interstitial processes is to say that there is molecular disease; hence disease of structure. It is, however, sufficient for the purpose, if, while admitting that the line of separation between functional and structural diseases is becoming more and more indistinct (and this is especially true in regard to the stomach affections), we content ourselves with defining functional diseases as diseases in which there is marked deviation from the standard of health, such deviation being a change in innervation and in the degree of activity of the organ and its capacity for effective work, and the expression of molecular alterations which are inappreciable to the senses.

Under the head of functional diseases of the heart we have to consider disorders of motility and disorders of sensibility.

The heart of the adult person beats between seventy and eighty times a minute. Its action is remarkable for its rhythmical character; so strong is the tendency to rhythmical contraction that in cold-blooded animals not only does the entire heart continue to act after removal from the body, but even separated portions will contract and relax with great regularity for a long time.¹ Each beating of the heart is composed of several factors; there is first the systole, followed after a brief pause by the diastole, and the cardiac revolution terminates by another pause longer than the first; then comes a new succession of similar systolic and diastolic impulses and pauses. It is moreover essential to the normal action of the heart that its function shall be accomplished without pain. This rhythmical succession of pulsations may be accelerated, or may be broken or become intermittent; the heart, instead of performing its work painlessly, may "suffer in every fibre," and it may give expression to an exhausted or anæmic condition by asystolia and syncope.

The heart's action ought not to be easily excited by trivial and varying causes, such as moderate exercise, change of posture, and taking food and stimulants. If liable to excitement by trifling circumstances it is, as Broadbent has pointed out, an unfavorable sign.²

It is apparent that in describing functional heart derangements we cannot present any clear-cut nosological demarcations, as it is in our power to do when describing the organic affections. Though there are doubtless pathological modifications of muscle, nerve, or ganglia, as the substrata of these derangements, we are unable at present to define them; we can only recognize certain

manifestations, which, arising from a variety of causes, are common to a variety of pathological conditions. In treating these manifestations as diseases, rather than as symptoms, some writers have introduced confusion into their treatises. Arrhythmia, for instance, is not a disease, it is simply a symptom and has widely different etiological antecedents, the proximate cause probably being the same in all cases. The same may be said of palpitations.

The heart may be deranged in its *power*, in its *rhythm*, and in its *sensibility*; hence the three fundamental divisions of functional heart-troubles, *asthenia*, *disordered rhythm*, *cardiodynia*. By this I mean that in all functional derangements there is predominance of some one of these characteristics, though all may co-exist, or any two may be intimately associated, as *asthenia* and *arrhythmia*. It is moreover worthy of note that all the valvular diseases and the degenerations of the myocardium are attended with one or more of these semeiological phenomena, so that in describing functional manifestations we are continually obliged to make incursions into the territory of admittedly organic diseases.

This is not all. Every prostrating lesion or ailment of the organism—a traumatism, a fever—produces some marked modification of the heart's innervation and nutrition, which expresses itself in deviations from the normal force and rhythm of the heart's action.

This explains why we cannot separate by a sharp line the functional disorders from the disorders occasioned by profound perturbations of the economy. The exaggerated, rapid action of the heart in certain pyrexial states cannot generically be separated from that quick, vehement action which characterizes palpitations, and can only be differentiated by arbitrarily classifying palpitations as *appyrexial*, or by insisting on the tumultuousness of palpitations (ordinarily so called), or the element of distress which so often characterizes these excited throbbings.

I.—ASTHENIC FORMS OF HEART DISEASE.

An asthenic condition, in which the heart, in its laboring mechanism, is overcome by fatigue, malnutrition (or both), is at the basis of all the functional troubles of this organ. If integrity of myocardium and ganglia persist, the heart will grapple effectively with its tasks, and if augmenting difficulties must be met by hypertrophy, hypertrophy will ensue. There will be increased action, with a pulse varying according to the occasion, but all will be within physiological limits. Excessive muscular exertion, hindering as it does respiration and the free passage of blood through the lungs, entailing thus undue fulness of the venous system and overloading the right heart, makes it difficult for the left ventricle to fill the systemic arteries; if nutrition be maintained at a high mark, the cardiac muscle may continue to do its work well, but if nutrition be inadequate, and especially if the heart be whipped into increased activity by alcoholic stimulants, muscular contractility is exhausted, the cardiac ganglia become anæmic and irritable, passive dilatation with disorderly action takes place, and all the symptoms included under the name of the forced heart.

The temporary perturbations of the heart's action, which occur under the influence of hard work, are too familiar to everybody to require insisting on here. That, moreover, sudden or prolonged distention of the fatigued right ventricle may cause passive dilatation of that side of the heart, with the necessary cortège of symptoms, is admitted by all authorities. The following fact, related by Clifford Allbutt, *à propos* of himself, is an example to the point. During a journey in Switzerland, after several days of fatigue, in which he was climbing mountains difficult of ascent, he was seized with strange shortness of breath, accompanied by very painful sensations of oppression and beating in the epigastric region, and percussion revealed an increase of precordial dulness. These troubles as well as the precordial dulness disappeared after a season of repose, but returned as soon as he again un-

¹ Carpenter's Human Physiology, Am. ed., page 241.² Broadbent in Braithwaite's Retrospect, part liv., p. 237.

dertook to climb the Alps. In the night-time he was awakened by an intense dyspnoea and painful palpitations; the precordial dulness was greater than it was before; full inspirations from the open window calmed this oppression.¹

If, then, it be admitted that there exists a primitive dilatation of the heart, as a result of overtaking that organ, and if anything which impedes the free return of venous blood to the right heart, may favor such overtaking of the heart with consequent dilatation, it is plain that pulmonary lesions which are attended with venous stasis in the respiratory organs, and which also affect the chemical constitution of the blood, must powerfully modify the heart's action, and may give rise to all the symptoms of the forced heart. In pulmonary emphysema, chronic bronchitis, and in congested states of the lungs generally, you have all the conditions of such dilatation from forcing of that organ.

Germain Sée, in an interesting chapter in his book on "Diseases of the Heart," shows clearly how renal affections may give rise to various cardiac troubles, and especially to the phenomena of the forced heart. The mechanism of these pathological manifestations has been alluded to in Part I. of this series. "You will," says Prof. Sée, "hear patients complain of shortness of breath, of being oppressed after the least exertion, of having a continual sensation of weight in the precordial region, of the occurrence of sudden violent attacks of palpitation; the pulse is sharp and vibrating, the heart voluminous, the shock of the apex very low down and very strong. You would naturally suspect the existence of some disease of the orifices and cavities, and yet auscultation reveals no abnormal bruit. Under these circumstances you may inquire if you have not here to do with cardiopathy of renal origin, and the existence of polyuria, the presence of a light opalescent cloud of albumen in the urine, the detection at a given moment of Potain's sign, the *bruit de galop*, will help you to a correct diagnosis."²

If pulmonary and renal disease may give rise to such symptoms, it is equally true that hepatic and intestinal diseases, attended with capillary-venous stasis may occasion the same pathological condition of the heart, and by the same mechanism as above described.

Nor should the stomach be omitted in this category of causes. I am at present attending a lady who has all the symptoms of the exhausted heart from chronic gastric catarrh. The heart of this patient has long been disturbed in its innervation and nutrition by gastric derangements, and has manifested its suffering by palpitations and decided rhythmical irregularities. There is at present marked passive dilatation of this organ.

Whether all these etiological conditions—overwork, pulmonary, renal, hepatic, gastro-intestinal lesions—may cause not only curable dilatations, but also permanent disorders, such as hypertrophy with endocardial inflammations, followed by valvular incompetency and degenerations of the myocardium; in short, the whole train of symptoms usually referred to primitive valvular disease, is a question which is not yet definitely settled, but to which an affirmative answer seems justified by the observations of Peacock, pertaining to Cornish miners; of Thun and Fraentzel, in the German army; of Myers, in the English army, and of Da Costa, in the American army.³

II.—DISORDERED RHYTHM.

As a result of asthenia of the heart's muscle, or impairment of some portion of its nervous mechanism, we have certain disorders of rhythm known as arrhythmia, intermissions, and palpitations. There is irregularity in the succession of pulsations, or in the duration of certain elements

of the cardiac cycle (the *arrhythmia* of authors); or the action of the heart is regular with now and then an interruption of its pulsations (*intermittences*); or the heart beats tumultuously and rapidly yet with a certain regularity of rhythm (*palpitations*). In palpitations the characteristic feature is *ataxia* rather than *arrhythmia*, yet they are no less a deviation from the normal rhythm than are the other irregular manifestations of the irritable myocardium.

1. *Arrhythmia*.—In the normal state the cardiac cycle is composed of the following elements in the following proportions: (a) the systole which comprehends the first part of the cycle; (b) a brief silence which with the diastole comprehends the second third; (c) a pause (the long silence) which occupies the remaining third of the cycle.

Instead of this normal succession with the respective time which belongs to each element of the cycle, the systole may be prolonged so as to occupy one-half instead of one-third of the entire revolution, the diastole and the pauses are then cut short; or it may be abridged in its duration and the diastole may be prolonged, moreover, the length of either of the pauses may be increased or diminished.

In other instances the want of rhythm may pertain to the *succession* of pulsations, which present great irregularity, being broken by pauses or intermissions of greater or less length. The beats may be now slow, now rapid and tumultuous, but their marked feature is irregularity.

The elements of the cardiac pulsation may be increased, the cycle being represented by a double systole or a double diastole, without any other interruption of rhythm. This is called *numerical arrhythmia*. There is a species of arrhythmia described by Guttman ("Handbook of Physical Diagnosis," p. 183) as "intermission of the pulse." In observing the pulse, it is noticed that after several regular strokes, one, or sometimes two, are omitted. This is due either to periodical interruption of the heart's action, or to want of power in the heart to send its pulsating throb into the radial arteries. Such an intermittent pulse is doubtless compatible with integrity of the heart and its valves, but it is often the result of mitral stenosis or insufficiency.

Pathogeny of arrhythmia.—It is when the heart is not in condition to respond to the demand for increase of labor that we note the arrhythmic pulse. All forms of arrhythmia are met with in connection with mitral insufficiency, especially that form which is characterized by reduplication of one of the heart sounds, or suppression of the first pause and the diastole. The left ventricle, unable as it were to fill the arteries by one systole, makes two or three partially successful attempts which infringe on the time of the diastole. Heidenhain, who has made an exhaustive study of the arrhythmias, and who has actually produced arrhythmia in animals by the action of certain toxic agents which disturb arterial tension, considers these irregularities as generated by the intermediation of the nervous system, and as generally depending on irritation of the spinal cord. This irritation modifies arterial tension by affecting the vaso-motors, and embarrasses the heart whose pulsations become disorderly. The first phenomenon is augmentation of tension, which coincides with acceleration of the pulsations, then arrhythmia ensues, but this does not always appear; in fact, for arrhythmia to develop, the augmentation of tension must exceed two hundred millimetres by the manometer.

This was shown by some very curious experiments of Heidenhain on curarized animals. This experimenter also observed that in electrizing the divided peripheral ends of the vagus, arrhythmia was produced.

If an excitation of the spinal cord exceeding a certain intensity may produce arrhythmia it is easy to understand that the causes which produce such excitation may be multiple, and that they may be toxic, acting through the blood, as when arrhythmia is produced by tobacco; or they

¹ Clifford Allbutt, cited by G. Sée (*vide* Boston Med. and Surg. Jour., January 4, 1883).

² G. Sée: *Maladies du Cœur*, etc., p. 277.

may be of reflex order, originating in some disturbance of the gastro-hepatic system, or the uterus; or of the blood-vessels, owing to augmentation of the peripheral resistance. Arrhythmia is not seldom seen in connection with nephritic disease, with or without hypertrophy of the heart. Lastly mental emotion, by its perturbation of the cardiac intra-cranial and spinal ganglia, may produce arrhythmia.

2. *Intermittences.*—The action of the heart is regular, except that now and then, and with more or less periodicity, there is a brief suspension. The heart beats normally, only after every four, eight, ten pulsations there is a momentary arrest, when the series of beats is resumed in an orderly manner. After the pause the first pulsation is generally stronger than those that follow, as determined by the finger on the pulse at the wrist and by the sphygmograph. Marey has explained this fact in the following way. By reason of the arrest of the heart the tension augments in the blood-vessels, to overcome which there must be either augmentation in the frequency or the force of the succeeding pulsations. Onimus, by electrizing the pneumogastric nerve with currents much interrupted, succeeded in producing intermittences followed by exaggeration of the force of the pulsations. The causes of intermittence are obscure; when not symptomatic of lesions of the heart they are reflex and are due to gastric or ovarian irritation, etc., or toxic, the result of the abuse of tea, coffee, alcohol, tobacco.¹

3. *Palpitations; accelerated rhythm.*—It is now generally agreed that palpitations are an evidence of want of power, not of excess of action. They indicate, as J. Milner Fothergill many years ago pointed out, that the heart is laboriously striving to meet the demand made upon it, and that compensation is incomplete.²

Germain Sée³ in his treatise on the anomalous forms of heart disease, defines palpitation as an increase of the activity and not of the energy of the heart. The idea intended to be conveyed is essentially the same as that of Fothergill in his lucid description first published in the *Lancet* in 1870: "The heart, when its integrity is impaired or it is exhausted by effort, *palpitates*, i.e., a laborious evident effort takes the place of the steady normal contraction." A balance has been struck between the weak heart and the systemic forces, the latter having been levelled down to meet the working capacity of the former. Any demand made on the heart for more effort causes palpitations, or even syncope, which are an expression of disturbance of the balance.

In palpitation we have acceleration of the pulsations of the heart which frequently seem diffused over an unusually wide area, without augmentation of its contractile force, as determined by the finger on the pulse and the sphygmograph.

How are we to explain the diffusion of the heart-shock in palpitations? In hypertrophy the heart opposes a larger extent of surface to the chest-walls during systole, and the impulse is strong and heaving and is felt in the arteries, which are distended. But hypertrophy is not commonly associated with palpitations, which are on the contrary a marked symptom of dilatation, whether organic or functional in its origin.⁴ In dilatation the heart

labors with diminished strength; there is perhaps more vehemence and excitement than in ordinary calm work, but less effective action. Now it seems more than probable that over-distention is an accompaniment of a large part of the cases of palpitation met with in practice.¹ But over-distention is only the precursor of dilatation, and these are but stages in the downward series of degenerative changes which have asthenia for their source.

It may be said that whenever the heart laboriously struggles against an obstacle which it is powerless to overcome, then we have palpitations. Many cases of palpitations in hysteria, with spasm of the systemic vasomotors, are of this kind.

Palpitations are often connected with displacements which embarrass the heart in its function and overtax its powers. Pleuritic effusions may displace the heart, so may tympanic distentions of the stomach or colon, by pressing upward the diaphragm and diminishing the working area of the heart. Sée accounts for many of the cases of palpitation of gastric or intestinal origin, whether in dyspeptics or hysterical patients, by such flatulent distention. The tympanic stomach encroaches on the heart and interferes with its movements. Polysarcoma may have the same effect.

Severe hemorrhages, by weakening and anæmiating the heart's muscle, may produce palpitations. I see no explanation of these palpitations but that of impaired tone and nutrition in the heart and its motor-energizing ganglia.

That the fundamental condition of palpitations is impairment of tone is apparent from the good effects generally attending the administration of digitalis, convallaria, and other powerful heart tonics—an argument, by the way, on which Fothergill insists.

All causes which anæmiate the heart—insufficient food and exercise, mal-aëration, depressing passions and vices, the abuse of intoxicants, and even tobacco, which interfere with healthful digestion and nutrition, and all other debilitating influences, such as continued fevers and traumatisms, which affect the circulatory system conjointly with the economy generally—are etiologically associated with palpitations. Therefore it is not a matter of surprise that palpitations should be common to the anæmic and chlorotic, to the convalescent who too soon attempts labor, to the emaciated needle-woman whose scanty wages enable her to eke out only a miserable existence, to the inveterate smoker whose dyspeptic stomach digests little food, and even to many tea-drinkers whose meagre slice of toast is washed down by many cups of their favorite beverage.

In these cases of anæmic palpitations there is generally much excitement of the heart's action with a systolic blood-murmur at the base, propagated in the direction of the large arteries. The *bruit de diable* in the jugulars is often very marked. These patients are easily put out of breath. The pathological condition is deficiency of red globules and the nutrition of all the tissues is below par.

But there is another standpoint from which to view the subject—that of the nervous system. There are powerful co-operative factors in states of the intra-cardiac or extra-cardiac ganglia or nerves. As to conditions of the intra-cardiac ganglia in their relation to palpitations, we know nothing.

The vagus, besides being the inhibitory nerve of the heart, contains the vaso-motor and trophic nerves of that organ.² While recent investigations have proved that the

functional, and its presence in cases of organic palpitation" (John Cockle, in *Lancet*, December 24, 1859, p. 636).

¹ I have qualified the above statement, which does not always hold good. There is evidence that some cases of palpitation are dependent on *too great irritability* of the heart-fibre, from loss of blood, inanition, or even toxic agents. The heart beats rapidly and impetuously, though feebly; its action is like the hobbling trot of the jaded horse: it does not even wait for a good diastole before it empties itself of the little blood that its ventricles contain.

It is, moreover, a fact, which Professor Sée has pointed out, that palpitations do not *per se* lead to hypertrophy, as would be the case were they constantly and invariably the concomitant of dilatation. Cases of so-called essential chronic palpitations have been noted where the heart for a series of years has maintained a remarkably accelerated rhythm; the autopsy has disclosed no valvular lesion, no dilatation, no hypertrophy (G. Sée, loc. cit., p. 572).

² Brown-Séquard, in maintaining that the par vagum is the true vaso-motor

¹ M. Decaisne, in a communication addressed to the Académie des Sciences, states that in the course of three years he has met among eighty-eight inveterate smokers twenty-one instances of marked intermittence of the pulse, occurring in men from twenty-seven to forty-two years of age, and not to be explained by organic lesion of the heart. The absence of such lesion or other condition of health capable of inducing intermission of the action of the heart, and the fact that in many of those instances in which the use of tobacco was abandoned the normal action of the organ was restored, M. Decaisne believes will justify him in concluding that in certain subjects the abuse of tobacco may give rise to a condition which may be termed *narcotism of the heart*, characterized by intermission in the movements of that organ and in the pulsations of the radial artery; and that in some cases a suspension or diminution of the practice of smoking is sufficient to cause an entire disappearance of this irregularity.

² Palpitation, Its Diagnostic Value. London *Lancet*, Aug. 6 and 20, 1870.

³ G. Sée: *Diagnostic et Traitement des Maladies du Cœur*. Second Edition. Paris, 1882. Also *MEDICAL RECORD*, vol. xxiv., p. 286.

⁴ "Slightly dilated hearts are, as is well known, much more prone to attacks of palpitation than those in the opposite condition of simple hypertrophy. I would here allude to the distinction between palpitation of organic and of inorganic origin, and observe that now and then, perhaps, the surest diagnostic sign between the two conditions is the absence of marked dyspnoea during the paroxysm of

vagus contains certain accelerator fibres, moderate and careful stimulation of which increases the frequency of the pulsations, it is certain that the ordinary effect of excitation of that nerve is to slow or arrest the heart, and there is no reason to doubt that this is the usual physiological action. By galvanization of the cardiac end of the vagus, then, you may produce arrhythmia, but you will not be likely to produce palpitations. If, however, you cut this nerve, then something very much resembling palpitations ensues. There is great acceleration of the heart's pulsations, which become tremulous, unequal, and less energetic than in the normal state.¹ Another phenomenon resembling palpitations is noted when in animals this nerve is divided. They become anxious and distressed, and this is strikingly like what we observe in the human subject when suffering from palpitations.

It would seem, then, that experimentally palpitations may be produced by section of the pneumogastric, and this makes it appear probable that the so-called "nervous" palpitations in man may have their origin in paralysis of the vagus. Sée has even gone so far as to account for nearly all palpitations in this way. If powerful emotion may cause palpitations, it is through a paralyzing action on the vagus centre. He appeals to the instance of fear, which causes pallor of the face and coldness of the extremities, by excitation of the vaso-motors; in the same way, he says, the emotion has caused anæmia (by vaso-constriction) of the bulb, and the vagus centre. If tobacco causes palpitations, it is through paralysis by nicotine of the cardiac ganglia of the medulla oblongata. So with tea and coffee. In anæmia and chlorosis the vagus-ganglia are often at fault, and neglect properly to rein up the heart, and the so-called reflex palpitations are distant irritations becoming paralyzing lesions of the pneumogastric.

All this is in the present state of our knowledge largely speculative. What we do know is that palpitation is a phenomenon of asthenia; that it accompanies states of debility, and is often reflex or irritative in its origin,² and seems to be dependent on a withholding of the special trophic and energizing influence of the vagus centres. It is certain that no mere irritative or paralyzing lesion of the spinal or sympathetic cardiac centres can *per se* produce palpitations. Von Bezold, Ludwig, and Thiry have indeed proved that excitation of the spinal cord at different heights produces acceleration of the heart's action, but it also increases the energy of the heart; the heart beats faster, but more efficiently. It seems to be almost certain, moreover, that this augmentation of the cardiac contractions is secondary to contraction of the systemic arteries, brought about by stimulation of the vaso-motor centre in the spinal cord.

Increasing knowledge of the causes of palpitations is showing that they are often caused by morbid states of the blood. If the poison of nicotine may produce palpitations by its depressing action on the vagus-centres, perhaps also on the myocardium, so may blood poisoned by bile, or lithic acid. When we know more about lithæmia, now becoming a prominent study among medical men, we shall know more about certain obscure palpitations which have been regarded as "gastric," "nervous," or hypochondriacal in their origin.

III.—CARDIODYNIA.

The heart, though "the most sensitive of the organs of the vegetative life," seldom expresses by pain the difficulties which it experiences in accomplishing its tasks.

nerve of the coronary arteries, affirms that its irritation causes contraction of these vessels, and thus, by preventing the passage of blood into the cardiac tissue, diminishes the frequency of and ultimately suspends the heart's beat, while on the other hand the section of this nerve, by allowing the coronary arteries to become overfilled with blood, excites the heart to preternatural pulsation. This explanation, simple and plausible as it may seem to be, does not cover the cases of palpitation from anæmia.

¹ G. Sée: loc. cit., p. 156.

² The heart may often be remarkably slowed in its action (pulsus tardus). This may be due to intrinsic causes (fatty degeneration, atheroma of the aorta), when it is presumed that there is mechanical irritation of the cardiac branches of the vagus (Guttman). It is, however, often due to extrinsic causes, as in grave disease of the higher nerve-centres, and results from disturbance of the vagus—innervation.

Any considerable degree of cardiodynia, then, should justify the apprehension that actual gross structural disease exists.

There is now a general consent among pathologists that angina pectoris is an organic, and not a functional disease. The latest researches seem to have established this beyond any reasonable doubt. Dr. Henri Huchard has lately published a series of articles in the *Revue de Médecine* (April, June, August, and September, 1883), in which he shows by an exhaustive *résumé* of the evidence that *true angina pectoris* (Heberden's disease) is due to ischæmia of the heart-muscle, the result of obstruction by calcification or atheroma of the coronary arteries. Other forms of cardiodynia are nervous, reflex, toxic, or diathetic, and are curable—these he calls *false angina pectoris*. The nervous form is that condition of the cardiac mechanism which has its origin in the state of the nervous system accompanying hysteria, neurasthenia, hypochondria, exophthalmic goitre,¹ etc. The reflex form takes its point of departure in some distant irritation, as of the stomach, uterus, etc., which is reflected on the intra-cardiac sensory fibres of the pneumogastric. The toxic form is perhaps oftener caused by tobacco than by any other agent, though cases have been referred to tea, coffee, and alcohol. The diathetic form accompanies rheumatism, gout, syphilis, and diabetes.

Huchard cites the following examples, which show the necessity of a proper diagnosis of these two forms of *angina pectoris*: "In gout we may have thoracic angor under three conditions—(a) either it is a true angina pectoris, arising from an arterial lesion (arterio-sclerosis, atheroma of the coronary arteries, lesions of the aorta, etc.), to which gouty persons are always predisposed; or, (b) gastric troubles, frequent in gouty patients, may provoke attacks of false angina pectoris, which is likely to terminate in cure; or (c) the angina pectoris may be a neuralgic paroxysm, such as gouty neurasthenic invalids are prone to."

In the case of tobacco-poisoning, the same clinical distinction ought to be observed. Tobacco may produce (though rarely) true angina pectoris, by spasm of the coronary arteries, or by favoring real arterial lesions, or, as is oftener the case, false angina by the neuralgic or dyspeptic troubles which it provokes.

These views correspond essentially with those of Professor Sée in the work to which I have so frequently referred.

In a third and final paper I shall take up the clinical aspects of the subject of functional heart diseases.

THE VALUE OF A CAUL.—The following advertisement appeared in one of the daily papers of this city recently: "Wanted—Any person to buy an infant's caul. Call at—Gouverneur Street, second floor." A reporter of the *Times*, calling at the place, found that the caul was priced at \$100! The owners informed him that there was a great demand for cauls among sailors and sea-captains, as it was firmly believed that no one with a caul was ever drowned. A party of interested ladies present informed the inquirer that cauls are more efficacious as remedies for the various ills that flesh is heir to than all the medicines in the drug shops, and declared "if any doctor had a lot of 'em to give people to hold or carry when sick there wouldn't so many die." Several marvellous cures were paraded. One cited a case of paralysis of thirty years' standing, another mentioned a case of inflammatory rheumatism, still another the case of a frightful attack of lockjaw, and, finally, hydrophobia and cholera were added to the list. The reporter heard enough to excite in him the gravest apprehensions for the future welfare of the regular medical profession, especially in view of the incentive to be born with cauls now held out to infants by the present high rates.

¹ Forms and Treatment of Angina Pectoris. Medical News, October 20, 1883.

PRACTICAL OBSERVATIONS ON THE HUMAN EAR AND ITS DISEASES, WITH ILLUSTRATIVE CASES.

By SAMUEL SEXTON, M.D.,

AURAL SURGEON TO THE NEW YORK EYE AND EAR INFIRMARY.

I.—THE EXTERNAL EAR.

GENERAL CONSIDERATIONS.

The external ear.—Inasmuch as the auricle and external auditory canal comprise the external ear in man, they may best be considered together as a whole, both in the study of their functions and in the treatment of the diseases to which they are subject. The auricle and its affections will, however, be more particularly noticed before taking cognizance of the external auditory canal and its diseases, and in certain instances it will be necessary to devote attention to these parts as a whole, their intimate relationship rendering them liable to be attacked by disease at the same time.

The traumatic lesions of the auricle are among those which seldom extend to the cartilaginous portion of the canal of the ear, and in regard to the pinna, or wing of the ear, it may be said topographically to be entirely unlike any other structure of the body; and consisting, as it does, of a delicate cartilaginous framework, occupying a prominently outstanding position, it is very much exposed to injuries from blows, either delivered accidentally, as in boxing and at play, or from falls upon the organ—even lying upon a hard pillow may, especially under favorable conditions to be alluded to further on, set up inflammatory action in the auricle; the injury in either case resulting from the auricle's being more or less forcibly pressed against the hard and unyielding temporal bone.

That the auricle is not more frequently the seat of disease from these causes may create surprise, when it is considered that the perichondrial envelope which everywhere lies in contact with the cartilaginous framework is thus so frequently liable to traumatic lesions, and its consequent separation from the cartilage through inflammatory effusion so sure to immediately follow, as will be seen under *othematoma*.

Cutaneous affections.—Injuries, however, by no means constitute the principal part of auricular affections, since the common integument, of which the outermost covering of the external ear consists, is liable to nearly all of the cutaneous affections to which the skin is elsewhere subject. But before proceeding to consider the various affections constituting these two principal divisions, it will be well to first take notice of some general characteristics of the external ear which have a special bearing on diseases of the auricle and its acoustic functions.

FUNCTIONS OF THE EXTERNAL EAR—ITS TOPOGRAPHY, PHYSICAL AND ACOUSTIC FUNCTIONS, COMPARATIVE ANATOMY.

Topographical description.—The pavilion of the ear, as the external ear is sometimes called, varies in size and shape in different individuals; the pinna, or wing, in its general contour is hollowed out like a shell, the *conque* proper being the deepest part and constituting the expansion with which the external auditory canal commences. The inequalities of the auricle's surface, depending on the foldings of the cartilage, while presenting a pretty uniform appearance to the casual observer, are, on close inspection, found to be differently moulded in almost every subject. So characteristically distinct, indeed, has this variation been found to be in individuals, that the remark is said to have been made by an eminent jurist that a photographic view of the ear would better serve for the identification of persons than a picture of the face even—the former not being in the same degree subject to the mutations of time or other changes to which the latter is liable.

The acoustic value of this portion of the ear in man

has not been as yet satisfactorily determined; this, however, is not because discussion of the subject has been wanting, and the assertion has been frequently made that excellent hearing may remain after the entire loss of the auricle. It is not strange, therefore, that some writers have considered the auricle as of but little, if any, use whatever as a collector of sound. Thus Itard (1821), in confirmation of this view, relates an instance where a soldier had both of his ears cut off without impairment of hearing, and Hennon (1830), in his work on "Military Surgery," says, "I have met a case where the external ear was completely removed by a cannon-ball, and yet the sense of hearing is as acute as ever." Inferences based on data afforded by cases like the two above cited are, however, by no means to be accepted without question, since there is reason to believe that inadequate tests were employed to ascertain the hearing-power; at least if the voice-test was carefully made the fact is not stated.

Notwithstanding the fact, however, that the loss of the ears does not entail very marked deafness on the sufferer, unless it be in the impairment of the hearing sense in regard to orientation, yet one cannot doubt that the more amply developed, though less becoming, pinna is the more serviceable acoustically, inasmuch as its larger receiving surface favors considerably the collection of sound, and probably also the appreciation of its source. In civilized society, however, the beauty of the ear is considered to depend very much on its small size, and, moreover, the possessors of such enviable adornments are not usually found to be defective in hearing on that account; but many persons moving in the better stations of life are embarrassed by the deformity of illy formed and unsightly ears, and the writer's attention has often been directed to this subject by patients and others; the feasibility of adopting operative procedures for correcting these deformities has been proposed even.

As has been stated above, writers have differed respecting the acoustic functions of the outer ear. Prominent among the older writers who have attached no little importance to the organ may be cited Du Verney (1683), and later Williams (1842) and Pilcher (1842). The observations of the former are of sufficient interest, after the lapse of two hundred years even, to introduce here. He considers the external ear as a natural trumpet, well adapted, from its neat and smooth concavity, to condense sound and consequently render its impressions stronger on the deeper parts of the organ of hearing. This is, he believes, confirmed by the experience of those from whom the external ears have been removed, for they do not hear so well, and use the palm of the hand or a trumpet to remedy the defect. He also adduces the habits of animals, as the deer and hare, as likewise significant—their habit being to turn the ears in the direction from which sound comes in order to hear better. Some persons, he says, believe that sound is reflected from the folds of the auricle before arriving at the concha and that thus intensified their impressions on the transmitting mechanism are increased, "just as in a half circular arch the rays of sound reflecting themselves at equal angles, the length of the circumference of the vault, pass finally from one end to the other by several great and small reflections."

Williams, and subsequently Pilcher, elaborated the previous literature of this subject, and their observations on the size, shape, mobility, and probable use of the auricle in man and in the lower animals, are of considerable interest. Charles H. Burnett (1877) and Rouis (1877) have both of them made researches respecting the acoustic functions of the external ear in man. Burnett concludes that the auricle and external auditory canal constitute a resonator for high notes.

But whatever the sound-condensing or resonating functions of the auricle and external auditory canal may be, these parts exert an important influence on audition in quite another manner. I allude to the direct mechanical

dominance through which elasticity in the drum-head is maintained, in the first place, by means of the cartilaginous framework which is firmly attached to the temporal bone, and, in the second place, through muscular action. Referring to these influences it is readily conceivable that the former aids in retaining the cutaneous layer, which envelops it and constitutes also the outer coating of the drum-head, in a state of proper tension, while its elasticity permits of varying degrees of tension in the drum-head without rupture whenever extra tympanal pressure occurs from either barometrical pressure or from the impact of loud sounds. In respect to the muscular dominance referred to in the second place, it may be said that the aural group of muscles exert a great influence on the transmitting structures, for while the outer integument, lining the external ear, is made to maintain the normal state of tension in the membrana tympani, the underlying fascia of the canal and contiguous parts is, when acted upon by these muscles, capable of increasing its usual tension. Besides the muscles known as aural, there are also certain muscles of the head which may be regarded as auxiliary aural muscles; but of these a fuller account will presently be given.

Impairment of the normal tension of these parts during the progress of inflammatory affections affecting them is quite frequent, and in availing ourselves of the acoustical knowledge to be derived from a study of the above facts, the presence of symptoms otherwise perplexing may be accounted for: thus deafness, tinnitus aurium, and autophanous phenomena, all of which are common in middle-ear affections, may be explained differentially when the outer ear only is the seat of disease. In this connection, let it be borne in mind that in consequence of old age, or from any cause whatever whereby general tone is lessened, the cutaneous layer of the outer ear may suffer relaxation, and that impairment of hearing, tinnitus, etc., may result. Patients thus affected frequently acquire the habit, seemingly almost involuntarily sometimes, of placing the open hand behind the auricle when in the act of listening attentively, and drawing it forward, thereby very much increasing the sound-collecting capacity of the organ, and also putting the parts upon the stretch—conditions which aid hearing considerably. Other patients obtain favorable results by placing the end of a finger in the conque and drawing it outwardly.

Comparative anatomy.—A study of the outer appendages of the hearing organ of some of the lower animals might add to our knowledge of the functions of the human ear. In venturing to offer a most superficial review of the subject, it would be well to state that some of the observations from which the following remarks were drawn were made more for the writer's own amusement and instruction than with any intention of presenting them as the result of strictly scientific enquiry; yet it is to be hoped that suggestions so unimportant as these even may stimulate further research in a department of science where our knowledge, considerable though it be, is still incomplete.

I am led at the outset to institute a comparison in this regard between animals inhabiting aerial and aqueous elements respectively. Thus it will be found that nearly all of the former have an outstanding sound-condensing auricle, while in marine animals this is usually absent. When a transmitting apparatus is found to exist in the latter even, no trumpet-shaped outward collector of sound seems to be required, since the momentum of aqueous undulatory movements is much greater than aerial. In marine animals which make excursions of greater or less duration into the atmospheric air, and are capable of existence in either element, as the whale, alligator, and the like, provisions exist apparently adapted to both aerial and aqueous transmission of sound.

In some crustaceans, however, there seems to be no membranous motor analogous to the drum-head, such as is required in aerial transmission of sound, and hear-

ing, therefore, is probably only complete when the animal is submerged. Scarpa (1795) and Weber (1820), who made researches respecting the hearing sense in these animals, held views differing from the above; they delineate, for example, an osseous and membranous vestibule in the fresh-water crayfish, supplied with an auditory nerve, and in this manner endeavor to explain the perception of sound. I have myself repeatedly dissected the sea-lobster, an animal similar to the river-lobster, with the view of substantiating the theory of the authors above mentioned, and have indeed found a minute nervous filament distributed to the part as described by them, but can scarcely believe it adequate for the needs of this animal, since the optic nerve is of much greater proportions than the so-called auditory nerve, and as regards the vestibules described, I have been unable to demonstrate them satisfactorily. It has occurred to the writer that perhaps the larger antennæ of the lobster are sound-perceivers; they seem well adapted to this purpose, since from their construction they may readily be thrown into vibratory movements. They have a wide range of motion and are easily moved by their own muscles. I have observed the action of this animal while at rest upon the bottom of the sea in shallow water, when the fluid surrounding him was suddenly thrown into vibrations by the blow of an oar upon the bottom of my boat: the larger antennæ were then immediately thrown upward, the better to ascertain, as it seemed, the source of sound. There is still further reason for believing that sound is perceived in this manner, for these antennæ are supplied with nerves of very considerable size, which are given off from the ganglionic centre near the origin of the optic nerves. If these views are correct the hearing sense is but a more highly specialized state of the kindred sense of touch, and much more primitive than in the sound-receiving and transmitting organs which are adapted to respond to the force of the aerial undulations which constitute sound; yet they are sufficient where a highly specialized hearing sense is probably not required.

If attention be now directed to the ears of aerial animals below man in the scale, it will be found on comparison that there exists a striking resemblance, although a very marked difference prevails in the relative size of the external muscles, those of the former being more fully developed. In man, owing to long disuse, they are comparatively rudimentary and useless, since he cannot employ them to move his ears in the same degree enjoyed by such animals, for example, as the horse and dog. In these animals the auricle is loosely attached to the head, and may therefore be more effectively employed in gathering sound in the act of listening, since the largely developed aural muscles can be brought into use in presenting the concavity of the ear in different directions. Having discovered the source of sound the concave surface of the auricle may, on observing the animal, be seen to be offered to it and kept in a more erect state—a position probably most favorable for the collection of sound. In the dog the entire scalp glides freely over the skull, thus facilitating the voluntary movements of the ear.

An opportunity was offered the writer by a friend to examine the ears of his dogs, and in availing himself of this privilege he found that in setters and other dogs where a strain of spaniel prevails, that the drooping ears seemed to afford a natural shield to the deeper and more delicate parts of the organ, which are much exposed in these frequenters of the water and rovers of the field. The cartilage of the pinna, however, is no larger than in breeds carrying their ears erect, being absent in the most pendant part, and that portion composing the commencement of the external auditory canal is much dilated, forming a very large concha, which, when the external ear is in repose, is folded up, thus protecting the ear from the entrance of foreign bodies, etc. When the pendant portion of the auricle is lifted up, so as to afford a better

view of the entrance to the external auditory canal, there are to be seen a number of operculæ, formed from the outer margin of the collapsed walls; one of these, larger than the rest, seems to correspond to the tragus in the human ear. When the animal is on the alert in listening the drooping auricle is lifted up and expanded and the pliant cartilage unfolded, the act being performed by the *retrahens aurem* and *attollens aurem*, which muscles together lift the auricle backward and upward with much energy, thus bringing a most efficient sound-collecting trumpet into use. The hearing is possibly further improved in fielding by the constant motion of the dog's head, his ears being thus frequently thrown up, the act giving greater exposure to the concha.

The act of expanding the auricle would seem to also render the drum-head more tense, and per contra, the dog is observed to droop his ears to loud and disagreeable sounds, the drum-head being probably relaxed in this way, while at the same time sound is more completely excluded by the collapse of the cartilage and the overlying and pendant auricle. In this manner more or less complete muffling of the sound-transmitting mechanism takes place, without which the sensitive hearing organ which these animals possess would be liable to injury from loud sounds.

Examples of the peculiar functions of the ear in animals could be multiplied here, for their suggestiveness has undoubtedly a value to the otologist, but I shall allude to but one: It is a well-known fact that the horse when viciously inclined throws his ears far back, an act analogous to that of a desperately angered person who shuts his eyes to the consequences of his own inconsiderate passion, and may be said to blindly rush on to his own destruction; so might one fancy that the horse, by means of this position of the ears, excludes sound to some extent and thus dulls one of the senses through which his submission might be brought about.

The rudimentary state in which the muscles of the ear in man are found has been already alluded to above; the ability to voluntarily move the auricle by them, however, sometimes exists to so great a degree as to be startlingly suggestive of his evolutionary existence; and while the limited muscular movements possessed by him would be totally inadequate for the ear-movements requisite in lower animals, yet the phenomenal accomplishments he is thus sometimes endowed with would seem to point to a not altogether inutile function. I have frequently observed patients draw the ear forward, and more rarely backward or upward, on the introduction of the aural speculum, or a probe or other instrument into the ear; sometimes this wincing is accompanied by tightly closing the eyes and is sufficient to materially impede the introduction of these instruments. Instances of moderate ear-wagging are too frequently observed to be of particular interest; the following, taken from among a large number recorded in my note-books, will, however, serve as an example on which to offer an explanation of the *modus operandi* of the phenomena and their significance.

CASE I.—Joseph C—, aged fourteen, came to the New York Ear Dispensary, in November, 1878, on account of defective hearing arising from chronic purulent inflammation of the middle-ear. During his examination it was observed that he readily pricked up his ears while listening, the auricle presenting well forward. The act seemed to be performed as if to aid the defective sense of hearing, and he was apparently unconscious of the movements made. When requested to move his ears, however, they were moved forward and backward with great ease. The power of moving the ears in the above related case was doubtlessly increased by the constant efforts made in listening.

A much greater amount of ear-movement undoubtedly exists than most persons are themselves conscious of. I have myself often observed the ears of different individuals, when unaware of any observations being made

upon them, and have seen the ear elevated by the action of the occipito-frontalis while employed in giving expression to the speaker's emotions; the ear dropping down again to its normal position without voluntary aid.

The following experiment, which was made in my office recently, is of interest in this connection: I observed that a friend with whom I was conversing elevated his eyebrows while listening, by contracting the occipito-frontalis muscle. He stated that the act was usually unconsciously done, but that he fancied it increased the acuteness of his hearing. In order to ascertain if hearing was thus increased, I placed a large vibrating tuning-fork just out of the range of his hearing; if he now promptly elevated the brows the sound of the fork could again be heard, and when the brows were again relaxed he again ceased to hear it; repeated contractions and relaxations of the muscle caused the sound to reach his ears in an interrupted manner, some object seeming to be now and then interposed. The weaker vibrations answered best in the above experiment. My friend, Dr. George B. Pomeroy, of Ohio, informs me that a person known to him always elevates his eyebrows in listening, a habit that often gives offence, since the expression gives the person a supercilious and overbearing expression, as if he doubted what was being said to him. My own observation has been that many persons contract the *orbicularis oris* when listening intently.

On inquiring into the *modus operandi* of ear-wagging, as it has somewhat facetiously been termed, it would seem that the power is not alone dependent on the action of the illy-developed muscles of the ear, namely, the *attollens aurem* and *retrahens aurem*, but that the *orbicularis-oris* and *occipito-frontalis* muscles, acting conjointly, exert a powerful auxillary force in this direction. In most persons the ability exists to bring the last-named muscles sufficiently into action to render tense the fascia in front of and just above the tragus, the motion being perceptible to the touch of one's finger if placed in front of the ear, and when this force is exerted, as it would frequently seem to be, upon that portion of the deep temporal fascia extending down along the anterior margin of the osseous meatus until lost in the anterior ligament of the auricle, the drum-head itself would then be made more tense, especially the more distensible portion, which is directly continuous with the integument of the external auditory canal, and which is known as the *membrana flaccida*. The writer made a dissection of the ear in a recent subject, in order to determine the extent of the motion thus transmissible through the deep temporal fascia to the motor (drum-head) of the transmitting mechanism of the ear. First the deep temporal fascia was dissected up to where it is blended with the anterior ligament of the auricle. At this stage of the proceeding it was found that traction on the deep temporal fascia moved the auricle freely. The anterior attachment of the auricle was then divided, and a section of the petrous bone was made by sawing down through the tympanum from above, separating the incus from the stapes and bisecting the tensor-tympani muscle in its bony canal, leaving the rest of the mechanism of the middle ear intact, with the exception of a slight laceration of the drum-head at its inferior segment. It was now found that if that portion of the tensor tympani left attached to the manubrium mallei was made taut and so retained in the grasp of forceps while traction was made as before on the temporal fascia, which had been dissected up, the transmitting mechanism responded promptly and became more tense than before. When alternate tension and relaxation was practised on the fascia the drum-head tightened and relaxed likewise, the motion being perceptible to the eye.¹ These apparently demonstrable influences of muscular action in the middle ear mechan-

¹ The above dissection and experiments were made with the aid of Dr. S. H. Pinkerton, Assistant to the Chair of Surgery, Bellevue Hospital Medical College, who has promised to make further researches in this direction.

ism in man are similar to those which in a more perfect manner are obtained in the horse, dog, and other animals by means of the voluntary action of their more efficient muscles.

On a previous page allusion has been made to the effect on hearing of alterations in tympanal tension, either through atmospheric pressure from without or within; it can now be seen in this connection that the membrana tympani may have its tension very greatly disturbed by alterations in the tone of the cutaneous lining of the ear, or of the fascia and muscles which have just been mentioned. In this manner an explanation may be found for the variation in hearing experienced by persons who alternately pass their time in the cold, bracing outdoor air, and in warm apartments. When the parts are toned up out of doors hearing is much better, usually, than when they are relaxed by indoor warmth.

With a knowledge of the significance of the relations between the different parts of the external ear and the middle ear mechanism, which I have above attempted to outline, one will certainly find it more easy to establish a differential diagnosis in diseases of any of the parts mentioned.

Progress of Medical Science.

OPHTHALMIA NEONATORUM.—Credé, in the *Archiv. für Gynäkologie*, vol. xxi., 2, continues his articles on "The Prophylaxis of Purulent Ophthalmia in the New-born." He recommends to adopt the following immediately after birth: As soon as the child has been washed, wash the eyes with clean water simply, and then put in a single drop of a two per cent. solution of nitrate of silver. He says he has not seen any unpleasant results from this plan of treatment, and has been able with it to reduce the percentage of cases in hospital practice to as low as 0.2 per cent. Slight congestion of the conjunctiva with moderate swelling occur frequently, but these soon disappear without special treatment within forty-eight hours.

PERIBERI, OR KAKKE.—In the *Louisville Medical News*, Dr. F. H. Enders reports the occurrence of sixty cases of this affection on a Japanese man-of-war that visited the Sandwich Islands. The patients examined after admission to Queen's Hospital, Honolulu, suffered from pain resembling cramp in the calves, œdema of the extremities, marked dyspnoea, had a quick, rapid pulse, high-colored urine scanty in quantity, and constipation. Dr. Trousseau, House Surgeon, put them on a diet of potatoes, fresh meat, lard, and fruit, administered squills and digitalis, and nearly all recovered who were taken to the hospital. As soon as the action of the kidneys was well established by the diuretics, tonics were given.

Of the whole number of cases there were thirteen deaths. Dr. Trousseau regards the diet as the cause, it being almost entirely of rice.

HOT VAGINAL INJECTIONS.—Dr. T. Naylor Bradfield, in the *New York Medical Journal*, directs attention to a possible consequence following the long, persistent use of hot-water vaginal injections. He relates a case, that of a girl twenty-three years of age, who had a very large hæmatocele, for which hot carbolized-water injections were repeated two or three times a day, not above 100° F., nor below 90° F., and continued for an hour at each time. Six weeks subsequently the patient complained of increasing numbness on the inner side of the lower extremities, with pain in the knees, constant tingling of the toes, with complete loss of power to stand or walk alone.

EARLY SYMPTOMS OF GENERAL PARALYSIS OF THE INSANE.—In a paper read at the annual meeting of the Massachusetts Medical Society, Dr. W. B. Goldsmith analyzed the initial symptoms recorded in the histories of one hundred cases of general paralysis of the insane, in which he points out the exceptional occurrence at an early stage of the disease of any well-marked characteristics; that physical and mental symptoms usually appear nearly synchronously, the most frequent and characteristic being defective articulation. He also concludes that changes in the pupils and disorders of the gait are less frequent, and have less value in diagnosis, than is usually ascribed to them. He found the patellar tendon reflex to be markedly supra-normal in nearly twenty-five per cent. of general paralytics, the presence of this symptom being of much value in corroborating diagnosis, its absence having, however, no significance. Hallucination, or impaired function of the special senses, is very rare as an early symptom; nor had he noticed in any case the diminution in the sense of smell, thought by Voisin to be very frequent in the early stages. In twenty of his cases the first "motor" symptom consisted in convulsions or loss of consciousness, and he urges the importance of careful inquiry on this head. Among mental symptoms the marked exhilaration, with delusions of wealth and greatness, usually considered to be characteristic, was present early in less than one-fourth of the cases; the more frequent change is simple failure of mental capacity and activity, and mental depression.

PHOSPHATE OF CODEIN.—The *Wiener Med. Blätter* for August 16th contains the mention of a new drug, the phosphate of codein, which has been prepared by Merck, of Darmstadt, under the direction of Professor Hegar, of Freiburg. It is intended for hypodermic injection, for which neither the sulphate nor the chlorate are suitable, being nearly insoluble in water. The new salt is soluble in four parts of water, and contains seventy per cent. of codein. It crystallizes in four-sided columns, and is similar to morphia in action, with the advantage of having less tendency to excite toxic symptoms. It is particularly suitable for sensitive patients.

THE RISKS OF MASSAGE.—Dr. Althaus, in the *British Medical Journal*, says that it is now time to cry "Hands off!" with regard to the indiscriminate manner in which the "Weir-Mitchell treatment" more especially is being applied to all cerebral and spinal cases. Many cases which would be benefited by rest are being treated by means of massage and exercises, so that more harm than good is done to the patient. Dr. Playfair also writes to defend himself from being included among those who carry on the massage treatment in an indiscriminate manner, and points out that massage is only a part, and by no means the most important part, of true treatment, the results of which, in well-selected cases, are so remarkable that it is not surprising that it should run the risk of being at times injudiciously and indiscriminately applied.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, November 17, 1883.

FRENCH MEDICAL JOURNALS.

WE sometimes have inquiries as to what foreign medical journals an American who wished to keep up his knowledge of European medicine had best take. At the present time, with the great excellence of English and American medical journals, it is hardly necessary for a general practitioner to understand French and German in order to keep abreast of the times. If, however, he is especially interested in some branch of medical science, or if he aspires to be well informed as to the progress of medical science, it is very important that he see French and German literature in the original. For it is probable that in about eighty per cent. of cases translations are emasculating processes.

In beauty of style and clearness of expression French medical writers retain pre-eminence. But this pre-eminence is least strikingly shown in the periodical literature. We venture to say that French medical journals, as a whole, are the worst that are published in any of the leading civilized countries, ranking after those of England, Germany, and America; and hardly, on an average, exceeding in quality those of Italy and Scandinavia.

This poor quality is partly due, no doubt, to their great number. Exchange lists are flooded with a mass of cheap weaklies and monthlies. They have also, as a rule, very little individuality. Most of them are made up of reports of the great Parisian medical societies: Académie de Médecine, Académie des Sciences, Société de Biologie, Société de Chirurgie, Société des Hôpitaux, etc. The last half of all French medical journals is consequently almost precisely alike.

The French journals do not, like those of America, keep *en rapport* with the profession at large. One finds in them no "correspondence," and very few original communications. The original matter consists largely of lectures delivered in some course at the Paris hospitals, or of communications read before a learned society. The young doctor, or the general practitioner, who holds no professorship, and who is a member of no city society, is rarely heard from in the journals. In fact, most of the literary work is done by a few eminent individuals and their pupils, whom we, in this country, would soon learn to look upon as monopolists.

One peculiar and sometimes attractive feature of French medical journalism is the *feuilleton*. This is a department where gossip, anecdote, and light criticism

are to be found. The *feuilleton*, however, needs to be well done or it becomes very stupid. In the palmy days of *L'Union Médicale*, under Latour, its *feuilleton* became quite famous, and was frequently quoted. Our French confrères have a fondness for anecdote and *bon-mots*, and several journals devote a space to collecting and presenting literature of this sort—not always of the cleanest kind. It has been said that a French surgeon or physician must make his *mot* in order to make his mark. At any rate French medical writers generally show some evidence of this kind of ambition. Locke has asserted that a man of wit cannot be a man of the best judgment, *ergo* witty men will not make great doctors. This law evidently does apply to France; while as for England and America there has not enough wit appeared for some years to spoil a single doctor.

The French journals have few editorials, and these are not of a powerful character, being generally composed of comments upon the last session of the Académie.

The leading journals of a prominent character are: *Le Progrès Médical*, which is published once a week, *L'Union Médicale*, *Gazette des Hôpitaux*, and *La France Médicale*. There are several weeklies devoted chiefly to giving reviews of medical progress, together with the usual instalment of society work. Among these are: the *Revue Médicale* and the *Journal de Médecine*. Some of the best of French journals are published monthly *e.g.*, the *Revue de Médecine*, *Revue de Chirurgie*, and the *Archives Generales de Médecine*. There are journals which minister to every possible specialty, but mineral waters and hydrotherapy appear to be particularly rich in journalistic organs. More attention is paid also to therapeutics both in journals and in society work than is done in other countries.

French journals are decidedly narrow in tone, and unenterprising in everything but local matters. Comparatively little attention is paid to other work than that which takes place in Paris. In fine, when contrasted with the modern idea of medical journalism which knows no nation or language, but takes contributions to science from every quarter, French medical journalism is narrow and provincial, and not too scrupulous about advertising proprietary medicines.

PSEUDO-MENINGITIS FROM TEETHING.

To a group of cerebral symptoms, appearing especially in weakly or rachitic children during difficult dentition and subsiding upon the eruption of the teeth, Dr. Guaita gives the name of pseudo-meningitis dentalis. As an example of this affection, he relates the case of a child, twenty-one months of age, who was taken ill with fever, constipation, slight bronchial catarrh, and a single attack of emesis. To these symptoms were soon added somnolence, grinding of the teeth at night, hyperæsthesia, slight strabismus, irregular pulse, the tache cérébrale, but no convulsions. All these symptoms disappeared after eight days, as soon as two upper molar teeth had pierced the reddened and swollen gums. The author regards this disease as of much more frequent occurrence than is generally supposed. During the years 1880 and 1881, 194 children under two years of age were reported to have died of meningitis in Milan. He

thinks that in many of these cases the actual cause of death was the above-described pseudo-meningitis. In the treatment of this disease, which may end fatally in bad or neglected cases, Dr. Guaita advises the relief of constipation by calomel, and the employment of active antiphlogistic and revulsive measures, such as ice-bags, leeches, and blisters.

OPIUM IN COMA.

DR. E. H. HALE, in his treatise on an epidemic fever, commonly called "spotted fever," which prevailed in Maine in 1814, says, page 227: "This was a disease of debility, and of very great debility. The congestions (page 231), including the coma, were produced by debility, as appears from their being effectually removed by stimulants (page 232). Evacuations of every kind invariably increased the tendency to coma, while opium, tonics, and stimulants, cautiously administered, as constantly diminished it (page 143). Opium was by far the most liberally used in cases of coma. Whatever may be the explanation of its mode of action, it is certain that this was a powerful agent in removing the deepest comas, which were not absolutely irrecoverable. For this purpose it was sometimes given in large quantities, both by mouth and by injections (page 121). As the coma came on, the tincture of opium, with some of the strongest volatile oils, such as peppermint or lavender, was given in small doses, frequently repeated (page 122). If these and other measures were not speedily efficacious, enemata, composed of yeast, brandy, and tincture of opium, were thrown up, and the quantity of these articles given by the mouth was rapidly and largely increased. Indeed, the only circumstance by which the exhibition of these articles could be regulated was the effect they produced. No quantity was considered to be large enough, until the coma began to be subdued. When that remitted these medicines were given more sparingly and with greater caution. This effect was uniformly produced by this course of remedies, unless the previous state of exhaustion had been extreme, or some unusual circumstance prevented the requisite quantity from being given."

GLYCERIN DIET IN THE TREATMENT OF FEVERS.

PROFESSOR SEMMOLA, of Naples, has recently made a contribution to the *Bulletin Général de Thérapeutique*, upon the subject of the use of a glycerin diet in acute fevers. Discussing first the subject of *aliments d'épargne*, or those substances which lessen tissue waste, the distinguished professor makes quite a furious onslaught upon the popular practice of prescribing alcohol in fevers. He does not have much faith in the antipyretic action of this remedy. On the other hand he does believe that alcohol always has some toxic action on the bodily tissues, "a toxic action common to it with all the other famous antipyretics, veratrum, digitalis, carbolic acid, etc." Although admitting that alcohol has some claim to belong to the *aliments d'épargne*, he believes that it is likely to cause cerebral, cardiac, and gastric irritation. He has, therefore, abandoned its use as a food ration in the treatment of severe fevers.

Professor Semmola states that for many years he has been casting about for some satisfactory *aliment*

d'épargne which does not have the disadvantages of alcohol. He thinks that it has been found at last, glycerin being the substance desired. This he has employed in the following formula:

R. Glycerin. pur. 30 grammes
Acid citric *vel* tartaric 2 "
Aquæ 500 "

M.

About an ounce of this is taken every hour, the whole being consumed in the twenty-four hours. Semmola finds it grateful to his patients, and believes that a lower temperature and an amelioration of symptoms occur.

As to its effect upon tissue metamorphosis, his statements are very positive. The amount of urea daily excreted diminishes under the glycerin diet from 6 to 7 grammes on the average (*i.e.*, from 38 to 31 or 32 grammes). Sometimes it falls as much as 10 grammes.

The effect upon the carbonic acid excretion is not stated. Still Semmola asserts that the evidence is positive that glycerin in fevers lessens tissue waste, and is therefore an *aliment d'épargne*.

His views do not correspond entirely with those of several previous observers who have studied the effects of glycerin upon non-febrile subjects.

Lewin and Munk state that glycerin has no effect upon the nutrition of the body or the elimination of urea. Cattillon and Tschirwinsky found that it first diminished and then increased the urea elimination.

A NEW TREATMENT FOR THE CURE OF GLAUCOMA.]

A THESIS recently submitted by Dr. A. Trousseau, late hospital interne, presents in a very confident way the claims for a new method of treating glaucoma. This method, which was first conceived by M. Badal, of Bordeaux, consists simply in exposing and stretching the external nasal nerve. This nerve, one of the terminal divisions of the nasal branch of the ophthalmic, contains vaso-motor and reflex-secretory as well as sensory fibres. The nasal or naso-ciliary nerve itself is intimately connected with the visual organ by a branch to the ciliary ganglion and by branches to the ciliary muscle.

Dr. Trousseau admits that the ordinary method of treating glaucoma by iridectomy is a valuable one, and submits the following list of advantages and objections: It often gives excellent results, but sometimes is utterly powerless.

Its chief value is in acute glaucoma, practised early. In the more chronic forms it is useful but not curative. In simple chronic glaucoma it sometimes checks the disease, but often aggravates it. It is dangerous in hemorrhagic glaucoma. The operation has been known to excite a glaucomatous attack in the opposite eye. The operation is not a simple one and is liable to accidents.

Our author sums up also the advantages and disadvantages of sclerotomy in the treatment of glaucoma. It does not, he says, give such constantly good results as iridectomy even, and though beneficial for the relief of the prodromata of glaucoma, its effects are not lasting.

The especial advantages of stretching the external nasal nerve are then enumerated by Dr. Trousseau, who has applied the method in ten cases. He finds that it

at once relieves the terrible pain, diminishes intraocular tension, and increases the acuteness of vision. The operation is a simple one, is liable to no accidents, and if it fails iridectomy can at once be performed. It may prevent the necessity of enucleation or of optic neurotomy.

It is evident that Dr. Trousseau has obtained some good results from his novel operation. If it is really of value, the profession will welcome the fact, since it places a remedy in the hands of the general practitioner and those not especially skilled in ophthalmological surgery.

Glaucoma, however, is a disease that requires prompt action, and cannot be trifled with, and it may well be questioned whether so simple an operation as nerve-stretching will have a permanent effect upon the disease.

THE WORK OF THE GERMAN AND FRENCH CHOLERA COMMISSIONS IN EGYPT.

DR. KOCH has made a report to the Home Secretary of the German Government regarding the work of the commission sent to Egypt to study the cholera. The commission had been in Egypt for about two months when this report, dated September 17th, was made. Its headquarters were at Alexandria, and the investigations were carried out at the Greek Hospital, in that city. Twelve cases of cholera were observed and ten post-mortems made. This is not a very large record, but sufficient opportunity was afforded to make the pathological experiments desired. The blood, the vomit, the dejections, and the viscera were carefully examined. Few micro-organisms were observed, except in the dejections and in the intestinal wall. Cultivations of the organisms found here were made, by the gelatine method; and mice, fowls, dogs, and monkeys were inoculated with them. These animals were also fed with specimens of blood, vomit, secretions, etc. In no case was anything resembling true cholera produced.

The organisms found in the dejecta were of the kind previously observed by other investigators, viz., micrococci, bacteria of putrefaction, etc. They did not seem to possess any special pathogenic or anatomical peculiarities. In the intestinal wall, however, there was found in great abundance a bacillus which claimed more attention. It existed in great abundance, and was found in every case examined except one, that of a man who had died from one of the sequelæ of cholera after having survived the direct attack. In cases where the intestine showed gross anatomical changes the bacilli had penetrated the follicles of Lieberkühn, and caused evident irritation. In some places they had accumulated between the glandular epithelium and the basement membrane. In the very severe cases they even penetrated into the submucous tissues. The lower part of the small intestine was particularly affected by the bacilli. They are described as being rod-shaped and resembling the bacilli of glanders. Koch was particularly interested in these organisms, because he had already a year before seen similar ones in specimens of intestine from four cases of cholera occurring in India. These specimens had been sent him for examination; but he had not, at the time, been able to draw any conclusions regarding them. Having found them again, however, he proceeded

at once to make cultivations and inoculations. His results were, however, as we have said, entirely negative. In a word, therefore, the investigations of Koch and his party have as yet thrown no new light upon the pathology of cholera. The germs described are much like those occurring in ordinary conditions of putrefaction. It has been suggested that since the intestinal wall, in the latter stages of cholera, becomes greatly reduced in vitality the bacteria might easily pass into it at that time, just as organisms of putrefaction usually pass into dead tissue.

On the other hand, Dr. Koch thinks that the research is not yet ended. The cases of cholera from which he obtained his specimens, occurred toward the latter end of the epidemic, when the specific virus, and presumably the bacillus, had lost much of its virulence. Hence the failure of the inoculations. Again, this failure may have been due to the fact that the lower animals experimented upon are not susceptible to cholera affection at all. In order to clear up these and other points, Koch has asked permission to be sent to India, where he can continue his studies. This permission, we are glad to say, has been granted.

Cholera is a disease which, from analogy, one could easily believe was due to the presence of a pathogenic organism. Science is to be congratulated that so competent an investigator as Dr. Koch is enabled to continue his search for it.

The French cholera commission has not yet, so far as we can learn, made its official report. According to unofficial statements, however, this commission has also found an organism, and has cultivated and inoculated it. The results, however, like those of Koch, have been negative.

CAN CANCER OF THE PENIS BE ACQUIRED BY INOCULATION FROM CANCER OF THE CERVIX UTERI?

CONSIDERABLE comment has been aroused, and naturally, by the statement of Dr. T. G. Thomas, in a clinical lecture recently delivered, that there was a serious danger of contracting cancer of the penis by sexual intercourse with women suffering from uterine cancer. Dr. Thomas asserted that "repeated instances of cancer being contracted in this way were on record." And he always warned the husbands of women suffering from this disease against the danger to which they might subject themselves.

In a subsequent letter to the *Weekly Medical Review*, Dr. Thomas modifies his first statements very much. He writes: "If in the heat of a clinical lecture I should have stated the matter so strongly, I desire to modify my assertions, for I cannot sustain them, either from personal experience or a knowledge of the experience of others. I have met with but one case of cancer of the penis which I thought had this origin and I have not at my disposal evidence of the frequency of this disease after such exposure in the practice of others. I always guard husbands from exposing themselves to the danger of sexual intercourse where uterine cancer exists, and from *a priori* reasoning should look upon the danger of infection where an abrasion existed near the frenum as one which should be always guarded against."

Meanwhile Dr. Paul F. Mundé has been investigating this subject, and presents the results in the *New York*

Medical Journal of October 27th. This gentleman, never having met a case of this kind himself, wrote letters of inquiry to Drs. T. E. Satterthwaite, W. H. Welch, and R. F. Weir, of this city, also to Dr. Zerny, of Heidelberg, and Th. Billroth, of Vienna. From all these gentlemen the answers were that in their experience they had met with no case of cancer of the penis which had been acquired by local contagion in sexual intercourse. The opinion was general that cancer, in all probability, was not transmitted in that way, although the *possibility* of the occurrence could not be entirely denied. Experiments made to test the question of the inoculability of cancer have almost always been failures. Langenbeck injected fresh cancerous material into the femoral vein of a dog, and, a few months later, found some small cancerous nodules in the lungs. But Dr. Welch quotes Virchow as saying that these nodules resembled primary cancer. Dr. D'Outrelepoint made experiments which were entirely negative, while Nowinsky claims to have produced two small growths out of forty-two otherwise unsuccessful inoculations. Demarquay, in an analysis of one hundred and thirty-four cases of cancer of the penis, found one in which the cause given was a local contagion. This author does not believe, however, that cancer of the penis is ever really contracted in this way. Dr. Welch quotes Langenbeck as saying that he had seen three or four cases caused by local contagion.

Both Zerny and Dr. Mundé refer to the fact that cancer of the finger has never been contracted, so far as is known, by physicians or nurses whose work obliges them to make frequent digital examinations of cancerous cervixes.

The interesting evidence thus collected by Dr. Mundé tends to show that there is very little if any danger of contracting cancer by sexual intercourse. No case indisputably illustrating this mode of origin appears yet to have been reported—unless Langenbeck has recently published those that he claims to have seen.

The evidence is by no means all in, however, and as few deny the *possibility* of local contagion, it is to be hoped that clinical researches regarding this important matter will continue.

News of the Week.

THE DEATH OF PROFESSOR DEPAUL, of Paris, is announced. Professor Depaul was well known for his contributions to obstetrical science, and to pædiatrics. He was a member, and at one time president, of the Académie de Médecine.

LARYNGEAL CHOREA.—This is so rare an affection that a writer in an English medical journal recently expressed doubt of its existence. Curiously enough, three cases have recently been reported almost simultaneously: two by M. Blachez to the Académie de Médecine, and one by Dr. H. D. Chapin, to the Neurological Society in this city.

SUICIDES BY TWO MEDICAL MEN.—The profession of London have been shocked by the suicide of two medical men, both committed under very sad circumstances. The first was that of a native of Afghanistan,

Mahomet Ismal Khan by name, who came to England some few years ago, and, after studying for the usual period at University College Hospital, qualified as member of the Royal College of Surgeons of England, and Licentiate of the Royal College of Physicians of London. Having qualified, his troubles began. He had spent all his capital in obtaining his qualifications, and it was necessary that he should do something for a livelihood; but his extraction and color were against him, and, to his intense disappointment, he found that he could not obtain employment in the profession he had adopted without descending to practices both degrading and illegal; and, in a fit of despair, he committed suicide by swallowing a large dose of prussic acid.

The other case of suicide was equally sad. It was that of Dr. Dalton A. Haffenden, of Kensington, who was charged at the Hammersmith Police Court with being concerned in procuring abortion. At an adjourned hearing, it was announced that the doctor had committed suicide that morning by swallowing poison. He left behind him a letter, in which he declared his innocence of the charge.

THE STUDENTS MEDICAL UNION CLUB, of London, seems to be a failure.

THE PITTSBURGH MEDICAL JOURNAL will suspend publication for the present, after its next issue. The senior editor, Dr. T. J. Gallaher, contemplates a trip to Europe. This journal has been edited with more than usual ability.

SYPHILITIC INOCULATION OF MONKEYS.—At a recent meeting of the Société Médicale des Hôpitaux, Dr. Martineau announced that the monkey he inoculated on November 16, 1882, with syphilitic matter from a patient of his, after having presented the characteristic lesions—hard chancre, followed by the various syphilides (papulo-erosive)—became affected ten months after inoculation with ulcerous syphilide of the mucous membrane of the palate, which has healed. This case is interesting in so far as it proves that the evolution of syphilis in this monkey is following the usual course observed in man, and will tend to affect the theories in vogue respecting the natural history and origin of syphilis.

CONVICTED OF GRAVE-ROBBERY.—Last spring the grave of Edwin R. Harmon, formerly a prominent resident of Camillus, N. Y., was found to have been opened and the body stolen. The body was subsequently discovered in the dissecting-room of the Syracuse Medical College. Henry Thomson, formerly a medical student and a graduate of Syracuse University, was arrested for robbing the grave. His trial was concluded November 10th, and, after remaining out all night, the jury rendered a verdict of guilty.

DR. JOHN MCNEIL, an old and respected citizen of Jersey City, and one of the Commissioners of the County Board of Health, died at his home in that city on November 9th. During the war he was Surgeon of the Twenty-first New Jersey Volunteers.

THE END OF A CURIOUS CAREER.—Edward Borke, a well-known figure in connection with the Morgue in this city, died at Bellevue Hospital last week. Borke was a person who had probably handled more corpses than any

man in the world. The number of corpses in the Morgue each year approximates 5,000, and Borke handled every one entering or leaving it when he was on duty—in short, since his connection with the hospital he has moved at least 50,000 dead bodies. He had never followed any other calling but brick-making. The circumstances which led to his uncanny occupation arose in 1870. In that year he was brought to the hospital as a patient, and, although he improved rapidly, he never fully recovered. Being without home or friends he was allowed to remain at the hospital, and since has been in attendance at the Morgue and assisted at thousands of post-mortem examinations. Borke was not a man of tender susceptibilities, but he did his work faithfully, and had no bad vices. He was a very quiet man, and had little to say to strangers. His pet and most particular abhorrence was a newspaper reporter. For this portion of the community he held the most profound contempt, and could not disguise his wonder that any one in Bellevue Hospital should condescend to give them any information whatever. This dislike blossomed out, so the attendants at the Morgue say, after a reporter, who is now dead, had made Borke the central figure in a newspaper article, and compared him with Dickens's worthy, Jeremiah Crutcher. Borke read the article the following morning, and although he was ignorant of who Jeremiah was, he understood that he had been caricatured. He was wild with rage, and swore eternal enmity to the entire tribe of reporters, and kept it up.

THE CITY SCHOOL-HOUSES.—The Sanitary Inspectors of the city report that in many school-houses in this city the air is poisoned by bad drainage, defective plumbing, and insufficient ventilation. At a recent meeting of the Medico-Legal Society, it was stated that in two years 3,000 school children have lost their lives because of the foul and poisonous air which they have been compelled to breathe. The facts discovered by inspection are known to the Commissioners of Education, and there should be no delay in applying the proper remedy.

A DAILY MEDICAL JOURNAL.—Some enterprising parties in Paris have started a daily medical journal. It is called *Journal Medical Quotidien*. There are already two tri-weekly medical journals in that city; most of the journals, however, issue bi-weekly.

ARTIFICIALLY COLORED MEAT.—Several persons in Berlin were recently attacked with symptoms of poisoning after eating some beef which had a beautiful red color. It was discovered that the man from whom the meat was bought had colored it with aniline.

IMPROVEMENTS IN MOUNT SINAI HOSPITAL.—During the past eighteen months several improvements have been made in this hospital. There have been erected eye and ear infirmaries and an isolated building for cases of contagious disease. The inner walls of the main building have been renewed to guard against danger from the absorption of contagion by the walls. The cost of these improvements is about sixty thousand dollars.

A SECOND CLINICAL CHAIR IN OPHTHALMOLOGY has been organized in connection with the Vienna University and General Hospital. Dr. Ed. Ritter Gäger v. Jaxtthal has been appointed ordinary professor.

THE CHAIR OF ANATOMY IN DUBLIN UNIVERSITY has recently been filled by the appointment of Dr. Cunningham.

THE ELEVENTH ANNUAL MEETING OF THE AMERICAN PUBLIC HEALTH ASSOCIATION met in Detroit, Mich., November 13, 14, and 15, 1883. Dr. Ezra M. Hunt, of Trenton, N. J., was in the chair. A large number of new members were elected. Dr. D. E. Salmon, of Washington, read a paper on "Texas Cattle Fever." He gave a history of the disease. The malady does not spread from herd to herd, but is taken by those cattle which cross the trail of the infected ones. He felt sure that climate changes had little to do with the spread of the disease. Contagion always comes from infected pasturage, not from actual contact. The disease is never seen at the North, except where cattle from infected districts in the South have been put in the pastures. Dr. Hillare Ryan, of Caldwell, Tex., said he had lived in and near the infected district in that State nearly all his life. He had noticed that shrewd cattle-buyers would never purchase yearlings from the portion of the State referred to by Dr. Salmon.

Dr. J. M. Partridge, of South Bend, Ind., read a paper on the swine plague. This disease, generally known as the hog-cholera, first appeared in 1860, and its ravages were so frightful that the loss among the swine was greater than among all other classes of animals, being largest among the great corn and pork producing regions of the Northwest. The disease was the same wherever found. Some rather successful experiments with inoculation had been made, but it was thought best that the disease should be perpetuated instead of being exterminated. He recommended giving ten drops of carbolic acid for every one hundred pounds weight of the animal three times a day, and thorough disinfection of the pens with the same acid. Healthy animals should be separated from those diseased and removed to fresh pastures.

Surgeon George M. Sternberg, United States Army, read a paper on the "Etiology of Malaria." He doubted very much whether malarial disease was caused by the presence of parasites called bacteria in the blood. He thought it well established, however, that living micro-organisms were intimately connected with the presence of malaria. Tables were presented showing the number of cases of malarial disease at line posts along the Atlantic sea-board and at another line along the Mississippi and Missouri Rivers. Heat, moisture, and vegetable decomposition were essential features of malaria. Dr. Sternberg agreed with this proposition quite generally, but he also stated that the low state of the system was often, if not always, necessary for malaria to take effect. On the question of heat attention was called to the tables, which showed that the percentage of malarial diseases was much greater in Southern latitudes than at the North.

Following in the same line was a paper prepared by A. L. Woodhull, Surgeon, United States Army, on "Etiological Association of Organic Matter with Malaria." He thought it probable that the decomposition of organic matter—mainly vegetable—was the root of the evil. More directly he thought the causes were impure air and water and personal neglect of hygienic laws. Thorough drainage, he said, often prevented the spread

of periodic fevers. Dr. Clark Bell, of New York, said his experience had been that stagnant water, containing decomposed vegetable matter, was sure to produce malaria. He believed that malarial poison never crossed a very broad stream of water or a very wide expanse of sea. The theory he advanced for this was that water absorbed poison. Dr. George H. Rohe, of Baltimore, said malaria was not so dangerous in stagnant water as after the water had partially dried up.

Surgeon Charles Smart, United States Army, read a paper on the prevention of malarial diseases. With others he attributed the cause chiefly to impure drinking-water containing decaying vegetable matter.

At the evening session Governor Begole made an address of welcome on behalf of the State to the Association; Dr. William Brodie, of Detroit, on behalf of the city, and Dr. John Avery, President of the State Board of Health, on behalf of that body. The annual address by the President of the Association followed, consisting of a review of the work of the Association for the past eleven years. Social festivities followed.

Reviews and Notices.

A GUIDE TO AMERICAN MEDICAL STUDENTS IN EUROPE.
By HENRY HUN, M.D. New York: Wm. Wood & Co. 1883.

THE object of this book is "to furnish information about the different universities of Europe, and about the way in which medicine is taught abroad." After an introduction, containing a number of useful suggestions about methods of travel, and the manner and expense of living, the writer takes up the subject of medical study in Austria, Germany, France, and England, giving some space to each university in these countries. His preference for Vienna will be shared by all who have studied abroad recently. The well-known professors there, the numerous private courses given by their assistants in every branch of medicine, and the admirable facilities for the observation of patients in the great General Hospital are described in a way which indicates that the writer is a careful observer as well as a keen student. Several changes have occurred in Vienna of late which are not noticed, but as a whole this chapter will be found by the student full of valuable suggestions. The advantage to the student of obstetrics of arriving in Vienna during a vacation, when he can practice in the wards constantly without being disturbed by a crowd, should have been mentioned. The excellence of Heidelberg and Strasbourg as places for pathological work is noticed; but the writer hardly does justice to Berlin and Leipzig, which are really the great medical centres of Germany, and in which laboratory work in physiology, histology, and pathology can be done to great advantage. Paris has lost the place of pre-eminence which she held thirty years ago, when the present Nestors of American medicine were students. In one respect she is still in the front rank, viz., in anatomy, and the perfect facilities for work in the *École Pratique*, under M. Farabœuf and his numerous assistants, deserves a more extended notice than is given by Dr. Hun. The possibility of doing much satisfactory clinical study in neurology with Charcot, Magnan, and Legendre du Saulle, if one can secure an introduction to these gentlemen, is also passed by. The list of hospitals, with their location and hours of clinics will be of great service to the stranger. The chapter on England is simply a reprint of the student's number of the *London Medical Record*. It is undoubtedly a fact that Americans can study to better advantage on the Continent, where the

chief end of hospitals is medical instruction. But the opportunities for special work in London are very great. In gynecology or in surgery, for example, one can employ every hour in the week by attending the various hospitals and dispensaries, and is sure to receive a kind reception and some personal attention.

If a little more space had been given to a description of the methods of some of the prominent teachers; to pen-pictures of the great clinics of Nothnagel, Leyden, G. Sée, or Charcot, and to some details regarding the peculiar facilities for hospital work on the Continent, the book would have gained in general interest. No medical student starting for Europe should omit to take a copy. A thicker volume, somewhat smaller and of square shape, would have been more convenient to carry in the pocket.

THE INTERNATIONAL ENCYCLOPEDIA OF SURGERY.
Edited by JOHN ASHHURST, JR., M.D., Professor of Clinical Surgery in the University of Pennsylvania.
Illustrated with chromo-lithographs and woodcuts.
Vol. III. New York: W. Wood & Co. 1883.

IN the preface of this, the third volume of the *Encyclopædia*, its able editor expresses his confidence that it will fully sustain the high reputation already earned by its predecessors. That Dr. Ashhurst has not misplaced his confidence a careful examination of the book before us shows. Nor, in thus proclaiming his own faith regarding the value of his labors and that of his colleagues, has he, in our opinion, set aside any of that modesty which should always distinguish the editor of a large and important work.

With so little room for fault-finding, the task of the reviewer is naturally reduced to the simple one of presenting a brief analysis of the contents of the volume before him. Dr. Conner is the author of the first article, which is devoted to a consideration of the comparatively rare injuries and diseases of the muscles, tendons, and fasciæ. He writes in a terse way, and has happily omitted all superfluous details that sometimes mar the more elaborate chapters. The injuries and surgical diseases of the lymphatics are very ably treated by Dr. Bellamy, of the Charing Cross Hospital, London. In the third article, from the pen of the late Dr. John A. Lidell, we find an exhaustive and, at the same time, thoroughly practical account of the various injuries of the blood-vessels. This is followed by Dr. Wyeth's essay on "Surgical Diseases of the Vascular System." It is always pleasant to have to record the originality of an author's work; yet, perhaps, in a standard international work like the present the results of personal labors and individual convictions might have received rather less prominence than is here accorded them. The detailed enunciation of certain matters, more particularly some relating to histological changes, would more fittingly be found in some current medical periodical. Barring this slight fault, however, which one is the more ready to excuse on account of the intrinsic merit of his observations, Dr. Wyeth's article must be classed as among the best in the book.

Aneurism is next considered, and a better exposition of an important and difficult subject it has rarely been our pleasure to read. Dr. Richard Barwell, the author of this article, may well be congratulated upon the masterly manner in which he has acquitted himself of no easy charge.

Dr. Nicaise, of Paris, gives us a good account of the injuries and diseases of nerves. It leaves nothing to be desired in point of completeness and as regards the practical manner with which the subject is handled.

The concluding article is on the injuries of the joints, including dislocation, sprains, contusions, and the various kinds of articular wounds. It is by Dr. Andrews, of Chicago, and very aptly closes an excellent volume. The success of the *Encyclopædia* is now assured.

Reports of Hospitals.

PRESBYTERIAN HOSPITAL, NEW YORK.

SURGICAL SERVICE OF DR. GEORGE F. SHRADY.

(Reported by H. E. McCARROLL, M.D., House Surgeon.)

REPORTS OF PRACTICE AND PECULIARITIES OF TREATMENT.

IN a large metropolitan hospital with an active ambulance service the cases of acute surgery are quite numerous and varied, and are proportionately interesting and instructive. The Presbyterian Hospital has during the past few months been no exception to this rule. In fact, during this period the surgical wards have been crowded to overflowing with patients presenting almost every variety of injury. Reference is made to a few of these in a cursory manner for the purpose of illustrating the methods of treatment for some common forms of accident.

THE TREATMENT OF TRAUMATIC HEMORRHAGE.

As a rule, in all cases of traumatic hemorrhage the vessels are tied in the wound. There is an exception to this in scalp wounds, the bleeding from which is almost always controlled by firm compression. In securing vessels in an incised wound it is always considered wise, unless a vessel is only partly cut across, to limit operative procedures to mere ligation of visible bleeding points. In punctured wounds the contrary holds good, for when compression fails it is imperative either to enlarge the opening, tying both ends of the divided vessel in the wound, or to ligate the vessel higher up. In cases of hemorrhage attending compound fracture, where a main artery is not wounded, well graduated compression suffices. It has not been found necessary to depart from this rule in any of the cases of compound fracture treated during the present term of service. The most troublesome hemorrhages have been those due to incised wounds of the palmar arch. In all it has been found necessary to ligate the vessels in the wound. The manner of doing this may be illustrated by the following case:

G. V—, a milkman, aged twenty-two, while serving his customers fell forward, striking the palm of his left hand upon a broken bottle. The wound was situated about an inch and a half in front of the flexure of the wrist, and extended across that part of the palm, severing all the soft parts. The bleeding was at once very profuse. He ran to the neighboring police station, and the hospital ambulance was summoned. Bleeding was temporarily controlled by firm pressure and bandage. Soon after his admission Dr. Shradly applied an elastic bandage up the arm and an elastic tourniquet to brachial. The dressings were then removed. The main sources of the hemorrhage were, however, hidden in the deeper portions of the cut. The tourniquet was then loosened and the bleeding points seized in the following manner: A tenaculum was passed under a bleeding mass. Through the substance of this mass, behind the curve of the tenaculum and at right angles with it, was inserted a double ligature which was made to secure both halves of the included portion. By this method there is less danger of the slipping of the ligatures. As both palmar arches were involved it was necessary to apply three or four such ligatures. The wound was dressed as an open one, with carbolyzed oil, and is fast closing up.

LIGATION OF BRACHIAL ARTERY FOR TRAUMATIC INTERSTITIAL HEMORRHAGE.

Two cases were treated in the hospital recently which illustrate still another method of arresting traumatic hemorrhage. In both of these the respective arteries were punctured, and the blood escaped in the deeper tissues of the limb, forming an interstitial aneurism.

George K—, aged thirty-five, was welding steel by a

steam hammer, when a small shivered piece of the steel struck him on the inner side of the left arm at the bend of the elbow. A profuse hemorrhage which spurted through this small wound was temporarily controlled by a physician who saw the patient immediately after the injury. The patient had repeated seizures of hemorrhage at intervals of every two or three days for a week. At the end of that period he sought admission to the hospital in an almost exsanguinated condition.

Within a few hours after admission the blood found its way through the compresses. The dressings were promptly renewed, and the alarming hemorrhage which showed itself was promptly controlled by renewed pressure. Dr. Shradly was then summoned to the hospital, when it was decided to expose the bleeding point and ligate. The patient was etherized, an elastic bandage applied on hand, forearm, and arm up to the middle of the latter, where an elastic tourniquet controlled the brachial artery. After the removal of the bandage a free longitudinal incision was made at the bend of the elbow, opening up a large cavity filled with a clot and exposing the inner margin of the tendon of the biceps and the triangular space between the supinator longus and pronator radii teres muscles. The parts were already extensively dissected by the effused blood. After careful search an opening was discovered across and half way through the brachial artery at the flexure of the elbow. The vessel was tied on both sides of this wound with carbolyzed silk, and the intervening portion divided. The hemorrhage was then found to have been arrested, and the wound was dressed by the open method. The patient made a prompt and satisfactory recovery.

LIGATION OF ANTERIOR INTEROSSEOUS ARTERY FOR CIRCUMSCRIBED INTERSTITIAL HEMORRHAGE.

The following is the history of a second case of traumatic hemorrhage illustrating the same general plan of treatment:

E. M—, a lad aged sixteen years, was brought to the hospital by Dr. Curtis, of Hawley, Pa., with a swelling of the middle of the left forearm following a punctured wound accidentally inflicted by the blade of a pocket-knife. The injury was received two months before and was followed at the time by quite profuse bleeding. Dr. Curtis enlarged the opening and secured what appeared to be the bleeding point. At all events the hemorrhage was thereby arrested and the parts in time nearly healed. Two weeks before admission and during a convalescence from measles an interstitial hemorrhage declared itself in the shape of a pronounced circumscribed swelling, the size of an orange, in the site of the original puncture.

On admission to the hospital the left forearm was found considerably swollen, and the thumb and fingers semiflexed. The latter condition was thought to be due partly to pressure upon the median nerve by the clot and partly by surrounding inflammatory processes.

After the usual precautions the parts were exposed by a free longitudinal incision over the swelling and the clots were turned out. In the layer of the deep flexors and in the sulcus between the flexor longus pollicis and flexor profundus digitorum muscles was a matted cord of tissue including the median nerve and the wounded vessel. The anatomical relations of the parts were somewhat disturbed by the dissecting blood-clot, but the artery ligated was believed to be, from its situation, the anterior interosseous. The wound was dressed by the open method, and passive motion applied to the fingers. In three weeks the boy returned to his home in Hawley, Pa., with the wound healed and with good use of his fingers.

CONCERNING THE ELASTIC TOURNIQUET.

The elastic tourniquet and bandage are used almost exclusively in this hospital for the purpose of controlling hemorrhage of the extremities, and entirely replaces

Petit's tourniquet, even where amputation is to be performed.

HOT WATER AS A HÆMOSTATIC.

In cases of persistent venous oozing from the surface of wounds, hot water, 120° F., is quite frequently employed, with very satisfactory results. This is generally applied by means of saturated sponges held against the part.

Reports of Societies.

NEW YORK NEUROLOGICAL SOCIETY.

Meeting of October 12, 1883.

WILLIAM J. MORTON, M.D., PRESIDENT, IN THE CHAIR.

DR. LEONARD WEBER read a paper on

THE NEUROTIC ORIGIN OF PROGRESSIVE ARTHRITIS DEFORMANS.

Having briefly recapitulated the symptomatology and etiology of arthritis deformans, the reader proceeded to develop his personal views concerning the nature of the disease in question.

He said that among the comparatively large number of cases of arthritis deformans which he had seen in the course of the last twenty years, he could not but recognize in sorrow and grief, fright, irritation and exhaustion of nerve centres by sexual indulgence, and the leading of a dissolute life, factors just as potent in producing the disease as rheumatic influences, if not more so. Again, remembering the symmetrical appearance and progress of the disease in most cases, no more plausible explanation seemed possible than the supposition of causes located in the central nervous system. The neuralgic and tropho-neurotic symptoms also supported this view, though it was not to be forgotten that in a spine stiff and deformed by arthritis there might easily occur changes of innervation, producing neuralgias and tropho-neurotic changes secondary in character. Finally, the negative results which he had had in treating polyarthritis deformans after the usual anti-rheumatic method, with iodides, colchicum, etc., and on the other hand, the very positive results obtained in similar cases by the galvanic treatment of the central nervous system, combined with a generous diet and the persistent administration of cod-liver oil and iron, led him to believe in the neurotic origin of the disease in many cases. It was through the failure of the old method that he first became convinced of the erroneousness of the conventional opinion of the rheumatic or gouty origin of this formidable malady. Up to the present no autopsies had been made with reference to the condition of the nerve-centres in this disease, and it would be a fit subject for future research to find changes in the cord, presumably in the anterior horns, which might induce certain forms of arthritis deformans.

With regard to the main features of the disease, he had this to say: as a rule, it began and developed very slowly, without any other symptoms at first but pains in one or more joints, which came and went either spontaneously or after exertion. Not infrequently the patient complained at this early stage of an unusually tired feeling in the joints. The pains were neuralgic in character, circumscribed or diffused through the limb. In the peripheral form the joints of both hands and feet, in the central variety the hip, knee, and spine, were the parts affected. In the course of time a great deal of stiffness and discomfort was experienced. The joints enlarged and became unshapely by the proliferation of hard, osseous protuberances on the outer surface of the swollen epiphyses, and creaking or cracking in moving or palpating the joints was perceptible to the patient as

well as the physician. The adjacent soft parts, particularly the muscles, showed in a comparatively early stage of the disease a degree of atrophy not at all commensurate with their passive condition alone, but much more due to peculiar nutritive changes of neurotic or myotic origin.

In the peripheral form the disease affected the joints almost symmetrically on both sides; in the central form the advance was irregular. In one case he had seen it remain stationary in the hip-joint for many years, but attacking some joints of the fingers and toes at last. In another case, a female patient, about thirty-five years of age, the upper part of the body only was affected. He has now a case under observation where nearly all the joints on the body were badly affected when he first saw the patient, who had been a helpless cripple for many months. The disorganization of the shoulder, knee, and particularly the hip-joint, lead often to a considerable shortening. In one of his cases, still under observation, the shortening of the one lower limb amounted to nearly three inches.

In the spinal vertebræ ankylosis was more quickly developed by the disease than in other parts of the body. One of his patients could neither bend nor turn her head when he first saw her, the entire spine being stiff, but there were no symptoms of compression or even remarkable irritation of the cord. The disease was slowly but steadily progressive; while it might remain stationary for a length of time, exacerbations were sure to follow. Fever or other great constitutional disturbances he had not noticed in its course. In a female patient, aged thirty-seven, he found the urine to have a specific gravity of 1.026, containing some sugar, and phosphates in abundance. Her mother had diabetes and was a sufferer from arthritis deformans at the same time.

The following cases were selected from his records as illustrative of the points he wished to bring out:

CASE I.—Mrs. M—, aged forty-seven; American; no syphilitic or hereditary taint, but a sister is reported to be sufferer from chronic rheumatism. Married early in life, went on the stage, and as a somewhat prominent actress led an active and varied life, experienced many changes of fortune, travelled a good deal, and never hesitated to expose herself to wind and weather, yet always enjoyed good health until two and a half years ago, when, after a premonitory period of worry and depression of spirits by the loss of the last piece of property she owned, she experienced pains in both wrists and elbow-joints, followed by swelling and distortion of the same. Hands and feet soon followed, and when I saw her first on February 27, 1883, she had not a joint that did not creak or crack or was not out of shape, except those of the clavicle and the lower jaw. The knees and spinal vertebræ were in the worst condition and the most painful. Standing or walking, even with support, was out of the question. Her urine contained phosphorus, no albumen. Sleep and general nutrition bad; bowels irregular. No treatment had so far done any good, but the disease had made rapid and steady progress. Ordered to take of propylamin (trimethylamin) 3 j., aqu. 3 viij., oleosacch. citr. 3 j., a tablespoonful ter in die before, and two pills ferr. sulph. and potass. carbon. after each meal; good food, and a tablespoonful of cod-liver oil three or four times a day. Galvanism to spine and the cervical ganglia of the sympathetic three times a week. The local and general improvement has been so satisfactory that she is now able to get up and around with the help of a cane, and to do light work with her hands. The pain and swelling and distortion of joints are much less; sleep and nutrition greatly improved.

CASE II.—Mrs. K—, aged thirty-four; German; married twice, had two still-births and two abortions; second husband had syphilis and died of phthisis. Patient presents no signs of either disease; no hereditary influences. In 1877-78 severe attack of bronchitis that

troubled her the whole winter, but eventually got well without any apparent damage to the lungs. After some years of trouble, anxiety, want and exposure, arthritis deformans broke out two years ago with pain and swelling of small joints of hands and feet, soon spreading to one knee, shoulder, and hip-joint. The disease was preceded by severe headaches, from which she suffers yet occasionally, but less violently. Some of the joints present a gelatinous feel, and several nodules of the above description can be felt beneath the integuments of her arms. No pain on pressure over sternum, clavicle, or tibia. Neither specific nor anti-rheumatic treatment, so-called, were of any service, but the disease has been very tardy in its progress, and the disfigurements of the joints are not to be compared to those of Case I. She has always been able to walk, though not without pain, and from time to time has been confined to her room. Appetite and general nutrition not good. The treatment described in Case I. was commenced in January, 1883, and carried out pretty regularly up to the present time, except as to the application of electricity. The result thus far has been satisfactory; further progress of the disease has been stopped; pain, swelling, and disabilities of locomotion are much less.

CASE III.—Mrs. K—, aged thirty-five; American; married, multipara. Father in good health; mother suffering from diabetes and arthritis deformans. Patient well built and nourished; living in good circumstances; has been for some years very unhappy in her domestic relations, and been often deprived of rest and sleep, and otherwise maltreated. After a series of premonitory symptoms, such as hemicrania and neuralgias in the upper extremities, she showed the first symptoms of the disease in the joints of fingers, wrists, and shoulders about a year ago. Her urine contains phosphates (largely) and a little sugar. The affection has made no great progress as yet, and the treatment has not been carried out well enough to be of great service, owing to irregular attendance on the part of the patient.

CASE IV.—Mrs. H—, aged fifty-five; multipara. No hereditary taint; no apparent cause other than a good deal of anxiety and grief on account of the persistent ill-behavior of her only son. First symptoms in small joints of fingers and toes five years ago. So far she has not experienced any great inconvenience from her affliction, but as often as she makes up her mind to take the propylamin mixture and cod-liver oil for some time great relief follows as to pain and swelling.

CASE V.—Mrs. S—, aged sixty-five; German; married, multipara. No hereditary taint, but a good deal of exposure to rheumatic influences in her younger days. First attack in her right hip-joint fifteen years ago, which led in the course of time to a shortening of nearly three inches, and now to complete ankylosis. No other joints suffered until recently, when several small joints of the hands and feet became affected and she had to take to her bed. Various sorts of cures were applied to no purpose. For the last three months she takes propylamin and the compound syrup of the hypophosphites, with the result that she is able to be about again and that no other joints have been attacked.

CASE VI.—Mr. G—, sixty years of age; Austrian; clergyman; single. Of good constitution and no hereditary taint. He served as a missionary in his prime, travelled extensively in South and Central America. He was, of course, exposed to the severe effects of unhealthy climates, and suffered many hardships besides. He had severe attacks of rheumatism, of which he got well, but eight years ago it settled in his right hip and left knee, and when I first saw him, five years since, he was in constant agony, confined to his bed for many months, and the above joints presented all the symptoms of advanced arthritis deformans. Some of the joints of his hands and feet had also become recently affected. His urine contained albumen in considerable quantities; there were amblyopia—the ophthalmological examination showing

the affection of the retina often found in Bright's disease—and atheroma.

By the use of the iodides and the other remedies he was but little relieved, but two seasons at the hot springs of Virginia removed the severe recent affections of the joints, relieved his kidney trouble, and considerably improved his eyesight. The old affections of his hip and knee remained as before, but ceased to give him much trouble, so that he was able to be about and attend to his clerical duties.

DR. E. C. WENDT, in opening the discussion, said that he had seen a number of cases of arthritis deformans, mostly in hospital practice, all of which had, under the usual plan of treatment, gone on from bad to worse. He had also seen one of Dr. Weber's cases, in which a marvellous result had been obtained, in a comparatively short time, by an entirely different plan of treatment. He thought the value of Dr. Weber's interesting paper lay mainly in the therapeutic suggestions which it contained; for if other observers corroborated the ideas here advanced a decidedly progressive step would have been taken. He thought it was important to elucidate the causation of the disease; mere symptomatic treatment was quite irrational.

DR. DANA remarked that the few cases seen by him had not illustrated the neurotic origin of the disease. In New York he was of the opinion that the disease was rarely met with in private practice. He had seen only a few cases in hospital and dispensary service; this was even true in the Marine Hospital for sailors, where rheumatism abounded. He recollected having seen one aggravated case; the patient was an old woman, some seventy years of age, who had suffered from the disease for sixteen or seventeen years. It began in the vertebral column, and gradually involved the hips, knees, and toes. She was so helpless that in order to evacuate her bowels it was necessary to place her in the horizontal position over a pail. The patient had Bright's disease, and died of apoplexy. Upon post-mortem examination deposits of urates were found in the joints of the great toes. The patient was poor, and surrounded by all the conditions favorable to the development of the disease.

Dr. Dana said he had seen some women of a neurasthenic type, women who had suffered from functional nervous disturbances, who developed a kind of inflammatory swelling of the fingers, so that in one case the hands became almost useless. He did not know but that later on in life these cases might develop into arthritis deformans, and if so, would illustrate the theory advanced in the paper. In considering neurotic inflammation of joints, Dr. Dana thought the relation of the trophic nerves to them, if there are any trophic nerves, should not be lost sight of. Never, so far as he knew, have we found any articular disease following from functional nervous trouble. The nervous difficulty must be organic. In no experiment upon animals, except where an organic lesion of the spinal cord has been produced, have we been able to produce arthropathies.

DR. WENDT did not know that the author's paper contained any evidence that the disease was developed from an organic lesion of the spinal cord. If there had been such disease of the spinal cord, improvement could not have been so rapid. He thought the neurotic condition was not the ultimate but an intervening cause. If we would go back sufficiently far into the history of these cases he thought we would find that there was at first a disturbance of nutrition, on the basis of which the neurotic condition developed.

DR. BURRALL wished he could add something to our knowledge of this subject. The disease was one we were continually meeting. It seemed to him to be an arthritis resulting from trophic changes. In two cases which he could now call to mind these changes resulted from worry. One case had gouty trouble. There was no uric acid found in the urine of patients suffering from arthritis deformans. As far as therapeutics were concerned, he

knew of only two remedies. The two remedies he would hope to derive beneficial results from the use of were arsenic, which is a nerve-tonic, and eupatorium perfoliatum (boneset).

THE PRESIDENT felt like adding a word in regard to the practical part of the paper. He had not seen many cases of arthritis deformans in private practice; he could only recall five. It was probable that most cases were seen by the general practitioner. In the first four he had met with unsatisfactory results; but in the last, becoming convinced of the fruitlessness of the anti-rheumatic plan of treatment, he had administered cod-liver oil, iron, and static electrization with great benefit to the patient. He was of the opinion that the disease occurred most frequently in the so-called neurasthenic. It was interesting to note that the first advocate of the neurotic origin of the disease was an American, Dr. J. K. Mitchell, the father of Dr. S. Weir Mitchell, now of Philadelphia. At this very early date, 1834, Dr. Mitchell announced it as his theory that acute, subacute, and chronic rheumatism were diseases of the spinal cord. The neurotic theory of the origin of the disease in certain subacute foras was a very attractive one. He was prepared to admit, as an argument in its favor, that the ordinary anti-rheumatic treatment fails to relieve the patient. In the next place, there is a well-understood relationship between the disease in question and well-recognized nervous ailments. We have only to call to mind the arthropathies of the myelites of traumatic neuritis of certain hemiplegias to find a defensible relationship to the changes in the joints characteristic of arthritis deformans.

DR. DANA remarked that as interesting as it might be to claim the theory of the neurotic origin of arthritis deformans for America, it was difficult to see how the information afforded by the President's remarks made it clear that such really was the case. The author of the paper had laid special stress upon the idea that arthritis deformans was an essentially different disease from acute or chronic rheumatism. Hence Dr. Mitchell could not be credited with the origin of this theory, as his claims concerned only acute and chronic rheumatism.

THE PRESIDENT did not think that Dr. Mitchell's claims were thus narrowly restricted. It was doubtless true, however, that these claims should not have covered all forms of rheumatism as known at his day.

DR. BURRALL incidentally called the attention of the members of the Society to the fact that there was at the present time a case of Charcot's disease in the wards of the Presbyterian Hospital of this city. Dr. Charcot claims that Dr. Mitchell was the first to associate joint disease with the central nervous system.

Correspondence.

RANDOM NOTES AND OBSERVATIONS OF A TRIP THROUGH THE GREAT NORTHWEST.

Motto: Go West, young man!
And if you can't go West,
Go as West as you can.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR: Before leaving Montana, it seems well to say a few words concerning its capital, Helena, which is also the acknowledged business centre of the Territory. Helena is nothing, if not queer and peculiar. It represents to-day an imperfectly matured conglomeration of the most opposite elements. Indeed, at present the new city seems all superstructure, which rests, apparently secure, upon the basis of a crude mining camp. Those curiously puzzling types of humanity, which Bret Harte's genius has rendered so familiar to the reading public, may still be encountered in Helena. Not precisely as they appear in the pages of that gifted author, however; for stern reality has robbed them of the poetic halo which there surrounding them, softens harsh truth and wakes our pitying sympathy by gently playing upon the chords of a common

humanity. But the passing stranger detects no redeeming features about most of these sombre, sullen, repulsive-looking fellows. They seem simply odious, nothing more. An involuntary sense of aloofness fastens itself upon you, and as you willingly pass them by you feel relieved.

In addition to these rougher characters, however, and mingling incongruously with them, are found various representatives of the older civilization of the East, and that still older one from across the ocean. Thus hard-faced men, with restless, anxious mien that plainly speaks of gambling, drink, and pistol, jostle the eager youth of slender build and pale complexion, the unmistakable gentleman, and probably a late arrival in this ever moving, busy crowd. Again, the primitive profanity of a waning era may still be heard in answer to the affected British of some Harvard stripling. All are slaves to a devouring ambition—that of getting rich quickly. All have come to try their luck. The very air you breathe seems charged with this strong contagion. Indeed, so intent are they on quick success, that they never dream of possible failure. And it must be admitted they do succeed. No longer as in the past, not yet remote from present, by the single method of gold-mining; but in many of the recognized and legitimate business capacities of the East, or as professional men.

Has vice found a safer abode and more congenial soil there than in the centres of Eastern wealth and fashion? Who shall say yes without some show of hesitancy? Certain it is that they display a touching openness about vicious pursuits and habits. Certain, too, that the refined and subtle hypocrisy of a more complex, because more advanced civilization, has not yet clothed the hideous nakedness of vice in misleading tinsel. But is Western vice, therefore, more disgusting, more sinful, more degrading than her much attired twin-sister of the East? It all depends upon the moral point of view, which is a shifting, changeable thing, half statute and half conscience. Openly, artlessly, without attempted guise, vice walks the streets of Helena in clear, broad day-light. At night it is becomingly illuminated by electric lamps. And the uniformed representatives of law and order calmly smile and pass by. Thus universally sanctioned, protected, and practised, perhaps it ceases to be vice at all, and becomes a mere peculiarity, an innocent pastime. As just stated, it all depends upon the point of view.

A noted divine, seeing what has here been faintly shadowed forth, said that he felt better satisfied with this condition of things than what obtains with us. For, he argued, where I can see the devil so plainly, I can easily fight and conquer him; it is the devil that hides behind a bush who is so hard to catch. Evidently, then, the influx of a few Eastern devil-fighters (and perhaps we could spare a few) would soon make Helena and towns of her stamp models of virtue, sobriety, and refinement—that is to say, from an Eastern standpoint. But enough of this. As George Eliot has it, "whatever benefit there may be in denouncing the evil, it is after all more edifying, and certainly more cheering, to appreciate the good." Hence let us hasten to remember that this city's life at present illustrates but a transition period from a lower to a higher level; that Helena has already achieved a commercial supremacy over many other ambitious towns; that there may be much golden truth in the proud boast of her citizens, to the effect that she is, in proportion to her population, even now the richest city in the world; that pure men and virtuous women have found abiding homes there; and that if we were all born good, it would no longer be meritorious to be so.

Soon after leaving Helena, the main range of the Rocky Mountains is crossed, the road now going over the Mullan Pass. Here a tunnel nearly four thousand feet long is building, and will soon be completed. Mr. E. V. Smalley has recently so well described this interesting region that your correspondent easily yields to the temptation of quoting from his letter:

"Approached from the East," he says, "the Rocky Mountains seem well to deserve their name. Gigantic cliffs and buttresses of granite appear to bar the way, and to forbid the traveller's further progress. There are depressions in the range, however, where ravines run up the slopes, and torrents come leaping down, fed by melting snows. Over one of these depressions Lieutenant John Mullan built a wagon road a score of years ago, to serve the needs of army transportation between the head of navigation at the Great Falls of the Missouri and the posts in Oregon. Mullan's wisdom in selecting the pass, which bears his name, was endorsed when the railroad engineers found it to be the most favorable on the Northern Pacific line. The road is carried up ravines and across the face of foot-hills to a steep wall, where it dives into the mountain side, runs under the crest of the Divide through a tunnel three-fourths of a mile long, and comes out upon smiling green and flowery meadows, to follow a clear trout-stream down to a river whose waters seek the mighty Columbia. The contrast between the western and eastern sides of the Main Divide of the Rockies is remarkable. On the eastern slope the landscapes are magnificently savage and sombre; on the western slope they have a pleasant, pastoral beauty, and one might think himself in the hill country of Western Pennsylvania instead of high upon the side of the great water-shed of the continent. The forest tracts look like groves planted by a landscape gardener in some stately park, and the grassy slopes and valleys, covered with blue and yellow flowers, and traversed by swift, clear brooks, add to the pleasure-ground appearance of the country. What a glorious place this would be for summer camping, trout fishing, and shooting, is the thought of every traveller as he descends from the summit with his hands full of flowers picked close to a snow-bank. Snow Shoe Mountain rises just in front, across a lovely verdant valley. Powell's Peak, a massive, white pyramid, cuts the clear sky with its sharp outlines on the further horizon, and a cool breeze blows straight from the Pacific Ocean."

The Cascade Mountain range divides Washington and Oregon into an eastern and western territory. To do even scant justice to the attractiveness of the varied scenery of either district is quite impossible within the limits of this letter. There seems to be spread out before the entranced view a never-ending series of variegated landscape wonders and surprises. Now you see a panorama of natural parks with all the luxuriant vegetation of the Pacific lands. Then dense, dark, forbidding forests, wooded with mighty firs and pine-trees. Again you are delighted by charming valleys, all smiling sunshine, that invite lingering rambles and long repose. But grander and more imposing far than these gentler pictures, the giant peaks of the Cascades rear their proud heads, clad in the pure white of perpetual snow, high into the clear azure of this Western sky. Before the overpowering presence of these dazzling summits, the memory of Switzerland's fair Alps shrinks into that dark recess of the mind which may be called a willing forgetfulness. It is only when the Cascades too have gradually faded out of sight that comparisons seem at all admissible. And Puget Sound, too, than which no finer inlet has crept landward to form deep harbors, well-sheltered, navigable, and attractive. Finally, that mighty current, the Columbia River, with its banks of unrivalled, ever-changing, richly colored splendor. Surely these Territories have a grander and more manifold natural beauty than may be easily found in the entire Union, perhaps in all America.

As for the climate of Washington and Oregon, two widely different regions must be distinguished, the Cascades separating one from the other. East of this range there is an annual mean temperature not unlike that of Pennsylvania. Short spells of extreme cold occur, but not too often. The air feels dry, so that the heat of summer seems less oppressive than with us. The morn-

ings and evenings are invariably cool, if not positively cold. On the other hand, the western region, lying beyond the Cascades, enjoys an equable climatic mildness, quite peculiar to itself. One great moderator of winter's severity is the Japan current. Snow is a rarity, but there is a prolonged rainy season to replace the frigid winter of the East. And finally, a bright, sunshiny, temperate summer compensates largely for the more or less steady drizzle of a rather dreary fall and winter.

There is little to say about the towns and cities of these vast Territories. With the single exception of Portland, in Oregon, their greatness and importance lie in no past or present. Their future significance, however, seems not too far ahead. It appears not as the rash guess of the enthusiast, but like the exact calculation of the astronomer, to predict for them a near destiny of business thrift, prosperity, and fame. Really one feels that for once the study of the infant justifies the prognosis of the man to come.

With a feeling of reluctance, then, as when parting from some new acquaintance of congenial mien and sympathetic manner, your correspondent turns to other matters.

But not without casting a farewell glance upon Portland, justly called the metropolis of the Pacific Northwest. This rapidly growing city already claims 40,000 inhabitants, and presents the general appearance of a new, enterprising, flourishing business town. In its peculiarly advantageous situation it combines with the facilities of the seaport all the conveniences of an inland town. Deep-going ocean steamers stud its numerous wharves, although the Pacific is nearly one hundred miles away. It is, besides, a distributing centre for a large land traffic, having several railroad depots. And it is quite characteristic of this far Western town to see the thick woodlands of the surrounding wilderness receding, as it were, only step by step as the city limits steadily extend and encroach upon them. Thus, without sensible gradation or intermediate link, primeval forest is here at once transformed into modern city.

The practice of medicine is somewhat peculiar in Portland. Physicians earn but small incomes, compared with the great riches accumulated in trade. The average doctor cannot get much beyond an annual income of from \$2,500 to \$3,000. A very few may receive \$10,000, which would appear to be the maximum limit. Add to this that bills are often difficult of collection, especially for the beginner; that the profession, unlike what obtains in most other towns in Oregon, is already overcrowded; that living, finally, is higher than in New York; and it will be readily perceived that there is no promising field here for the youthful medico. Rheumatic and malarial troubles are the most popular affections in Portland. Acute pulmonary diseases are said to be rare.

The Portland doctors have a Medical College with all the modern professorships, and two hospitals. They feel proud of these institutions. Moreover, they live content and happy in the absence of patient-stealing dispensaries. The *Portland Medical Advance*, however, is a thing of the future. At present they all read *THE RECORD*, and those who do not ought to.

In taking final leave of the new Northwest, this infant stripling of huge dimensions and great pretensions, it may not be amiss to briefly dwell upon a few, a very few, of the most prominent oddities of that region.

It is certainly odd what enormous vegetables they raise there. And it is quite odd to note with what pertinacity they intrude these growths upon the attention of the tourist.

From Fargo on, the attacks of the vegetarian begin. He is no dallying amateur, but a dead-earnest professional. He insists on your sharing the glow of pride that starts through his susceptible constitution while lost in rapt admiration of a huge potato, or an immense cabbage, or a giant pumpkin. Next year, he solemnly declares, they will be much bigger. This was an off-year for crops anyhow. And sure enough, at the next station they have

already attained additional size, although there too they are attended by similar comments. Well, these marvelous products of an extraordinary soil keep right on getting bigger and bigger all the time, partly at the successive stations and partly in the minds of the truthful farmers; until at length you begin to wonder, in a dazed kind of way, why on earth, from sheer stress of accumulated weighty vegetation, the earth does not tip over at that particular point.

It is, further, odd to note what stress is laid on bigness—generally. Quite apart from vegetable bigness, which has just been alluded to, they call everything that may typify or characterize the West, “something big.” It is this one attribute that appeals most directly, emphatically, and eloquently to the Western senses. Out there some few things are great, but everything is big—in the estimation of themselves.

Take the extent of Western territory, for example. It is the “biggest country on the face of the globe.” Of course, as regards this particular point, we of the East are almost as knowing as they of the West; for we also never allow suitable or unsuitable opportunity to pass without proclaiming that remarkable discovery to mankind at large. But what we hardly suspected is, that almost every single Western State or Territory is “bigger than all the rest of the world put together”—with a margin to spare for undiscovered countries.

This deplorable ignorance of geographical details constitutes one of the most serious drawbacks of an Eastern education—as your correspondent was repeatedly called upon to admit; which he always did with commendable alacrity, in deference to the acknowledged power and steady aim of Western arguments.

Again, it is odd to find in what high esteem they hold the surviving pioneers and early settlers. But no. On second thought that is not odd at all, only quite human and deeply touching. That fast-dwindling band of brave-hearted, whole-souled, toiling men, will not live to see their work completed. Pioneers never do. Yet their humble lives, spent amid dreary surroundings and filled with vicissitudes, will not have been lived in vain. Surely they will have served a higher purpose, and have fulfilled a nobler aim than the mere bequeathal to posterity of a sturdy race of honest, cheerful, hopeful workers. For they will once more have taught the world the glorious lesson that unostentatious heroism and patient toil need not be, nay, cannot be futile. Theirs, too, will be the proud victory of persevering energy, invincible determination, and unflagging spirits, against great natural odds and over the many obstacles of human ignorance, prejudice, or pride.

Doubtless the names of all these pioneers will ere long be consigned to oblivion, unmerited though it be. But let us hold the class, at least, in reverential memory. What they may have cherished as some fond dream alone we already see in incipient fulfilment. No prophetic foresight is needed to-day to predict that their early labors and trials will not have been fruitless. And so, with a parting pressure of the horny pioneer hands, we leave the new Northwest, confident that it will work out its own destiny of greatness, and with our God-speed on the journey.

Very truly yours,

EDMUND C. WENDT, M.D.

136 WEST THIRTY-FOURTH STREET,
NEW YORK, November 2, 1883.

CONCERNING THE EPIDEMIC OF MEASLES AT THE INFANT ASYLUM.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: The medical gentlemen connected with the management of the New York Infant Asylum, and Dr. Brush, of Mt. Vernon, occupy considerable space in your last issue in severe criticism of our report upon the epidem-

ics recently prevailing. There is so much misquotation of us, and such a reckless use of quotation marks, that we find it difficult to accept some of their statements as meant in earnest. We deprecate such discussions, and this is our final reply:

Had we been aware of the susceptibility of these gentlemen to measles, our report might have been modified to meet their views. The report in question was made to the Board of Managers, and according to facts and information acquired in a very usual and legitimate manner. It was not intended as a medical essay. The peculiarities of the epidemic we hope to elaborate at some future time, and under fitting circumstances. Yet we may be credited as having appreciated the severity of the diseases, and as noting the unusual number of recurrences of measles. Nor were we oblivious to the fact that such an experience was uncommon, or perhaps unique, but in publishing the statistics we meant no offence.

The declination of certain physicians to serve upon the asylum staff, and the resignation of others, as brought forward by Dr. Nicoll, has no very intimate bearing upon the accuracy of our report, and is but remotely associated with measles in general.

The communication of Dr. Brush, and that signed by Drs. Foster, Blakeman, Burrall, and Goodridge, are quite similar. For they both contain the same partial quotations from Ziemssen's “Cyclopædia,” and the same sentences, transferred from Dr. Louis Thomas' article on measles, without credit. (See sentences in each communication beginning: “Even Panum . . .” Then see Ziemssen, vol. ii., p. 43.)

We think it hardly fair to quote (from p. 42) only the following sentence: “Second attacks of measles are, according to the experience of most observers, exceedingly rare, as much so as second attacks of variola, scarlet fever, varicella, etc.” For, following this, Thomas says: “Third attacks are even less frequent, though their occurrence . . . cannot be doubted.” Then, too, the next sentence contains the account of a child who had measles three times within about three months.

In fact, in this article in Ziemssen over forty names of authors are given as reporting cases and epidemics where frequent individual recurrences of measles have been observed.

It is true that we did not personally witness each and every one of these attacks. Yet, from properly directed inquiries of the mothers, nurses, and resident physician and her assistant, and with the exercise of some judgment on our own parts, we arrived at the conclusions which justified our published report. We were led to accept these facts unaided by an acquaintance with the article in Ziemssen, and in ignorance of Dr. Cheadle's conclusion (*Brit. Med. Jour.*, December 20, 1879), that, from a personal analysis of twelve cases of measles he does not believe a previous attack affords any immunity. And, finally, we were not cognizant of the fact that Dr. Joel Foster had reported to the Executive Committee of the Board of Managers, on September 29th, “that since August 1st last an epidemic of a fatal character had raged, resulting in fifty-one deaths; appearing in measles of a malignant form, different from any known to him in his experience—of an obscure character, recurring twice, thrice, four, and five times in the same patient; the sequelæ of which was most dangerous,” etc., etc. (Printed minutes Ex. Com. Bd. Managers N. Y. Infant Asylum, September 29, 1883.)

Had we known of Dr. Foster's testimony, he being a physician of standing and of large experience, we should not have hesitated so long in accepting the statements of those in charge of the children as to these peculiar features. We now can only wonder why he should sign a protest against the results of his own observations.

E. BRADLEY, M.D.
F. M. WARNER, M.D.

ON THE USE OF WARBURG'S TINCTURE IN MIASMATIC FEVER.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: For many years, in treating miasmatic fever which would not yield to quinia, I have been accustomed to prescribe Warburg's tincture. According to my experience, it is worth all other succedanea put together.

About six years ago, a medical friend consulted me for intermittent fever, utterly rebellious to the power of the quinia salts. His health had suffered greatly and he was obliged to temporarily give up his practice. I prescribed the tincture of Warburg in half-ounce doses, taken on an empty stomach, early in the morning. It was rapidly and completely successful in its effect. Several months ago he applied to me with a recurrence of his old trouble, saying: "But doctor, don't give me Warburg. I think I'd almost as soon die as take it. Even when I look at the bottle containing it, I become nauseated. It is an awful dose to swallow!"

I begged him to go to his apothecary, have the tincture evaporated in a water-bath to such consistence as would allow it to be put into gelatine capsules, and to take the equivalent of a half fluidounce thus prepared.

It answered the desired end perfectly, without causing discomfort of any kind. Since then many patients have taken "Warburg's Capsules," with a like result. One of them contains the potency of two fluidrachms of the tincture. With some persons, rather too active purgation follows the ordinary dose of two capsules. This can be easily regulated, by leaving out or diminishing the amount of aloes in the original formula.

I have had excellent results, also, follow administration of the capsules made by evaporating the modified Warburg's tincture, in which the alkaloids of cinchona replace the sulphate of quinine.

In cases of intermittent fever which are prone to recur, after having been once broken, I rely much more upon the daily dose of two capsules—taken early in the morning—than on any other remedy known to me.

The evaporated mass becomes hard very soon, unless glycerine be mixed with it before filling the gelatine cups.

Very respectfully yours,

JOHN T. METCALFE, M.D.

Obituary.

JAMES MARION SIMS, M.D.,

NEW YORK.

THE sudden death on Tuesday morning of the distinguished surgeon, J. Marion Sims, was a shock to every one. Although lately he had not been in robust health, no one had reason to believe that his valuable life might not be spared for many years. Reaching the age of three score years and ten, he had a remarkably young appearance, and with a good claim for longevity, he was often heard to say that he expected to see his ninetieth year. Up to the last he was active, ardent, and laborious. Death was the result of heart-failure, attendant upon atheroma of the coronary arteries and fibrous myocarditis.

Dr. Sims was prostrated by a very severe attack of pneumonia three years ago, and he sank so low in that illness that his family and physicians thought for a while that he would die. He rallied, however, and recovered almost entirely, as it seemed, from the attack. The piercing cold weather of fall and winter in this climate was more than he could endure, and he arranged to spend his winters in Italy. He was to have sailed for Europe, with his family to-day, en route for his Italian residence. He had even planned to sail a week ago, but was prevailed upon to stay and perform an important operation. He said on Monday that he had not felt so

well in a year, and was in the best of spirits. In the evening of the same day, with his son, Dr. Henry Marion Sims, he attended a patient, and on his return sat down to write on his autobiography, about one-half of which he had finished. He complained of a little pain over his heart, but continued to write. He retired, but was restless during the night, and shortly before 3 o'clock on Tuesday morning he turned up the gas and wrote for a time in bed. A little later his wife noticed that he was breathing in a peculiar manner and hastened to call his son. When Dr. H. Marion Sims reached the bedside, his father gave one short breath and expired at 3.15 A.M.

Dr. Sims was born in Lancaster District, South Carolina, on January 25, 1813. His education began in the common school, and he was graduated from the South Carolina College in 1832. After studying for a short time at Charleston he entered Jefferson Medical College, Philadelphia, completing the course in 1835. He began practice in the following year at Montgomery, Ala., making a specialty of gynecology, though he also became known for his skill in general surgery. In 1845 he published a series of papers in the *American Journal of the Medical Sciences*, developing an original theory of trismus nascentium. About the same time he began a series of experiments in the treatment of vesico-vaginal fistula, and, after four years, perfected a method of curing a disease that had been thought incurable, by the substitution of sutures of silver for those of silk thread then in use. In 1853 he came to New York, and, in addition to building up a lucrative practice, succeeded in establishing a hospital for women. The institution was at first supported by private contributions, with a grant of \$2,500 from the Common Council, but in 1858 a charter was obtained from the Legislature, and the city gave the land at Fortyninth Street and Lexington Avenue upon which to erect the pavilions, with an appropriation of \$10,000. After a study of hospital architecture in Europe he decided to have the hospital built in pavilions. The first pavilion was ready for the reception of patients in 1866, and, unlike most philanthropists, Dr. Sims lived to see the institution which he founded surpass even his own expectations in importance and usefulness.

Dr. Sims's reception in Europe was of the most cordial and flattering character. By special invitations he operated in several of the great hospitals in Paris, Brussels, London, and Dublin, and his extraordinary success elicited the warmest praise from some of the most eminent practitioners in Europe. He was greeted in many places as one of the greatest surgical discoverers and operators of the age. The French people were especially impressed with him, and the French Government conferred upon him the order of Knight of the Legion of Honor. Honors were also paid to him by the King of the Belgians, and subsequently he was decorated by the Italian, Spanish, and Portuguese Governments. Dr. Sims took his family to Europe in 1862, and he spent a large part of his time there during the next six years. In 1870 he returned to Paris from New York to visit his family, which he had left abroad. When the Franco-Prussian war broke out Dr. Sims was induced to take charge of the Anglo-American Ambulance Corps as surgeon-in-chief. This was the first ambulance corps to arrive at Sedan, where it rendered services of incalculable value, and the fame of Dr. Sims was greatly enhanced by the heroism, energy, and remarkable skill displayed by him. He was the oldest man who left Paris in the ambulance service. Dr. Sims built up a large practice in France and Belgium, where his services were in constant demand among people of wealth and high social standing. His genial manners and magnetic social qualities made him very popular abroad as well as at home.

The subject of this sketch was, during his life-time, elected an honorary member of scores of medical and scientific societies in every part of Europe and in every part of this country. In 1875 he was elected President

of the American Medical Association. He was a member of the County Medical Society, of the Pathological and Surgical Societies, the Academy of Medicine, and the Neurological Society. Dr. Sims' most important literary works are "Trismus Nascentium," "Silver Sutures in Surgery," "Clinical Notes on Uterine Surgery," "The Microscope in the Sterile Condition," a "History of the Discovery of Anæsthesia," "Treatise on Ovariectomy," "Intra-Uterine Fibroid Tumors," and his Centennial address before the American Medical Association in Philadelphia, June 6, 1876.

During the past two years Dr. Sims spent a couple of months of each autumn in this city, the winters in Rome or Nice, and the remainder of the year in Paris and other parts of France. During this time he has written many articles on surgical subjects. The funeral, which was largely attended, took place at 10 o'clock on Friday morning, in the Madison Square Presbyterian Church, of which the dead surgeon was one of the oldest pewholders.

The autopsy was made by Drs. W. H. Welch and G. L. Peabody. Present: Drs. A. L. Loomis, W. H. Welch, J. A. Wyeth, and W. Gill Wylie.

The heart was found to be somewhat enlarged, with adherent pericardium. The valves were competent. The calibre of each coronary artery was markedly narrowed by atheroma, which was partly calcareous. In the muscular tissue, at the upper part of the interventricular septum, there was a patch of fibrous myocarditis as large as a silver quarter of a dollar, with the beginning of an aneurismal pouch. There was a similar fibrous myocarditis in the papillary muscle, which controlled the anterior segment of the mitral valve. Both ventricles were dilated, and the left hypertrophied. The lungs were slightly congested and œdematous. The parietal and visceral pleura on the left side was everywhere adherent. The kidneys and liver showed lesions of chronic congestion. Brain normal. Some atheroma of internal carotid arteries.

Army and Navy News.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from November 3 to November 10, 1883.

BACHE, DALLAS, Major and Surgeon. S. O. 238, par. 1, A. G. O., October 18, 1883, assigning him to duty at Willett's Point, N. Y., revoked. S. O. 252, par. 2, A. G. O., November 3, 1883.

STEINBERG, GEORGE, Major and Surgeon. Leave of absence granted October 4, 1883, extended one month. S. O. 255, par. 4, A. G. O., November 7, 1883.

VICKERY, R. S., Major and Surgeon. Assigned to duty at Fort Townsend, W. T. S. O. 149, par. 3, Department of the Columbia, October 29, 1883.

WOLVERTON, WILLIAM D., Major and Surgeon. Granted leave of absence for one month. S. O. 201, par. 6, Department of the East, October 24, 1883.

MERRILL, J. C., Captain and Assistant Surgeon. Granted leave of absence for one month. S. O. 201, par. 7, Department of the East, October 24, 1883.

PATZKI, J. H., Captain and Assistant Surgeon. Granted leave of absence for three months, on surgeon's certificate of disability. S. O. 254, par. 6, A. G. O., November 6, 1883.

OWEN, W. O., First Lieutenant and Assistant Surgeon. Relieved from duty at Vancouver Barracks, W. T., and assigned to duty at Fort Stevens, Oregon. S. O. 148, par. 2, Department of the Columbia, October 26, 1883.

WILSON, GEORGE F., First Lieutenant and Assistant Surgeon. Assigned to temporary duty at Fort Townsend, W. T. S. O. 149, par. 2, Department of the Columbia, October 29, 1883.

Official List of Changes in the Medical Corps of the Navy, for the week ending November 3, 1883.

GORGAS, A. C., Medical Inspector. Orders to the Naval Hospital, Mare Island, Cal., revoked, and to remain at Naval Hospital, Chelsea, Mass.

ROBINSON, SOMERSET, Medical Inspector. To the Naval Hospital, Mare Island, Cal.

DEARBORNE, F. M., Surgeon. To appear before the Retiring Board, November 5th.

GIHON, A. L., Medical Director. To represent the Navy at the meeting of the American Public Health Association at Detroit, Mich., November 13th.

HUDSON, A., Medical Inspector. To represent the Navy at the meeting of the American Public Health Association, at Detroit, Mich., November 13th.

EDGAR, J. M., Assistant Surgeon. From the Receiving Ship St. Louis, at League Island, Pa., to the Receiving Ship Wabash, at Boston, Mass.

AUSTIN, A. A., Passed Assistant Surgeon. To the Receiving Ship St. Louis, at League Island, Pa.

There were no changes during the week ending November 10th.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending November 13, 1883:

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
<i>Cases.</i>								
November 6, 1883.....	1	36	38	4	19	31	0	0
November 13, 1883.....	1	50	67	3	22	43	0	0
<i>Deaths.</i>								
November 6, 1883.....	0	16	6	4	3	19	0	0
November 13, 1883.....	1	21	8	1	1	23	0	0

AUTO-TRANSFUSION IN HEMORRHAGE.—Attention has been quite frequently called to the value of auto-transfusion in cases of severe hemorrhage. In the *Wiener Med. Blätter*, of February 23d, Professor Braun relates a case of inversion of the uterus in parturition with severe and almost fatal hemorrhage, in which this method was resorted to. Elastic bandages were wrapped around the legs, with an immediate dissipation of the alarming symptoms. The hips were raised, ether injected, and stimulants administered. The bandages were kept on for nineteen hours. This method is especially applicable to post-partum hemorrhage from any cause, and is easily and quickly applied, much more so than transfusion. Doubtless, so prolonged an application might have its dangers in a few instances, but the advantages would far more than counterbalance the dangers. It may be remarked that the inversion was caused by pulling on the cord of an adherent placenta, a far too frequent error, we fear, in view of the dangerous results which have in many instances followed it.

OÖPHORECTOMY IN A GIRL EIGHT YEARS OF AGE was recently performed successfully, by a French physician, Dr. Duchamp. The left ovary and a large part of the Fallopian tube were removed.

AN EPIDEMIC OF TRICHINOSIS has broken out in Saxony. Over four hundred persons are said to have been attacked. Moreover, it is German, not American pork, which caused the trouble.

CEREBRO-SPINAL FEVER.

(SPOTTED FEVER. CEREBRO-SPINAL MENINGITIS.)

By J. LEWIS SMITH, M.D.,

CLINICAL PROFESSOR OF DISEASES OF CHILDREN, BELLEVUE HOSPITAL MEDICAL COLLEGE.

SEVERAL years ago, before New York physicians had any personal experience with cerebro-spinal fever, an outbreak of it of moderate extent occurred at or near Long Branch, and, from its proximity, physicians were apprehensive that it might enter New York. Very interesting discussions consequently took place in the Academy of Medicine concerning the cause and nature of this malady, and theories, crude and unfounded, in consequence of inexperience, were then expressed. Unfortunately the fears of physicians who participated in that discussion have been realized. The disease entered this city in the autumn of 1871, appearing first among the horses of the large stables of the stage and car lines, disabling and destroying many of them. In December, 1871, it commenced among the people, and since that time it has not been absent from the city. Its unknown cause, which in country towns soon dies out or becomes inoperative, from the lack of the conditions which sustain and perpetuate it, finds in this great assemblage of people, and in the state of the streets and domiciles, the conditions favorable for its development and sustenance, so that cerebro-spinal fever is now fully established with us. It has become one of the scourges of childhood, destroying many lives each year, and injuring irreparably, by deafness or in other ways, many who recover. We are now much better prepared, by sad experience, to discuss this disease than were those physicians who participated in the debates alluded to above.

ETIOLOGY.

It is not improbable, from the clinical history of cerebro-spinal fever, and from recent discoveries touching the parasitic origin of several of the common constitutional maladies, that the obscure and mysterious cause of cerebro-spinal fever will yet be discovered by microscopical and clinical research. Leyden, indeed, has published in a recent issue of the *Cent. f. Klin. Med.*, p. 61, a paper on the micrococcus of cerebro-spinal meningitis, and M. Ernest Gandier (*Rev. Medicale*, June 3, 1882, New York MEDICAL RECORD, September 9, 1882) states that he has discovered in the blood and urine of a patient, examined fresh and with "antiseptic precautions," micrococci in great abundance. But proof is lacking that these micrococci sustain a causative relation to the disease.

At the debates in the Academy the question was raised whether the cause might not reside in the cereals or some other agricultural products. This is improbable, for of two adjacent localities, in which the diet of the inhabitants is the same, one escapes and the other is visited by the epidemic. The disease ceases after a time, although the food of the people remains unchanged. Infants at the breast having only the mother's milk are sometimes affected, and likewise certain animals whose food is very different from that of man, and finally the most careful examinations have hitherto failed to discover any dietetic cause of the malady. That the cause does not emanate from the soil, directly at least, is probable from the fact

that many epidemics commence in the winter when the ground is frozen, and that they occur in localities where there is every kind of soil and the most diverse geological formations. Probably, therefore, the cause, whatever its origin and nature, resides in the atmosphere, and enters the system through those channels which receive air. Prof. Wm. H. Welch writes to me on this subject: "Worthy of consideration, though unproven, is the view of Medin, that the infectious material is absorbed by the lymph-spaces of the nasal mucous membrane, which, according to Key and Retzius, communicate on the one side with the atmosphere through openings between the epithelial cells, and on the other side with the subarachnoid spaces at the base of the brain."

Among the conditions which are favorable for the occurrence of cerebro-spinal fever, and may therefore be regarded as predisposing to it, we may mention the winter season. Statistics collected in Europe and the United States show that while 166 epidemics occurred in the six months commencing with December, only 50 were in the remaining six months of the year. According to the statistics of Prof. Hirsch, which were collected mainly from Central Europe, 57 epidemics were in winter or winter and spring, 11 in spring, 5 between spring and autumn, 4 commenced in autumn and extended into winter, or into winter and the ensuing spring, and 6 lasted the entire year. I suspect that the opinion expressed by Prof. Hirsch is correct, that the excess of epidemics in the winter months is due mainly to the greater crowding and less ventilation in the domiciles during the cold than warm months, especially among the European peasantry. In New York City, where the state of the domiciles is about the same the year round, the season appears to exert little influence on the prevalence of the disease.

All observers have remarked the fact that anti-hygienic conditions increase the liability to cerebro-spinal fever; in other words, produce such a state of system that it more readily yields to the morbid influence and contracts the malady. Hence soldiers in barracks and the poor in tenement-houses suffer most severely when the epidemic is prevailing. In New York City the fact is often remarked that multiple cases occur for the most part where obvious unsanitary conditions exist, as in apartments which are unusually crowded and filthy, or in tenement-houses around which refuse matter has collected, or which have defective drainage. The interesting chart prepared under the direction of Dr. Moreau Morris for the Health Board, shows that comparatively few cases occurred in the epidemic of 1872 in those portions of the city where the sanitary conditions were good. Anti-hygienic conditions probably predispose to cerebro-spinal fever in the same way that they do to other grave epidemic disease, as for example, to Asiatic cholera, whose ravages are chiefly where hygienic requirements are most neglected. We will presently relate striking examples which show how foul air increases the number and malignancy of cases.

Is cerebro-spinal fever contagious?—It is the almost unanimous opinion of those who are most competent to judge from their observations, that it is either not contagious or is contagious in only a slight degree. It is certain that the vast majority of cases occur without the possibility of personal communication. Thus, in the commencement of an epidemic, the first patients are affected here and there, at a distance from each other, often miles apart, and throughout an epidemic, usually

only one is seized in a family. Children may be around the bedside of the patient, passing in and out of the room without restriction, and yet we can confidently predict that none of them will contract the malady, if there be proper ventilation and cleanliness, and none of the conditions of insalubrity exist within or around the domicile. Moreover, when multiple cases occur in a family, the disease begins at such irregular intervals in the different patients, that there can be little doubt in most instances that it is not communicated from one to the other, but, like the fevers from marsh miasm, is produced by exposure to the same morbid cause, existing outside the individuals, but within or around the premises. Thus in the Brown family treated by the late Dr. John G. Sewall, of New York (New York MEDICAL RECORD, July, 1872), the first child sickened January 30th, and subsequently the remaining five children at intervals respectively of five, seven, eleven, twenty-five, and forty-five days. That so many were affected in one family was attributed by the doctor to the filthy state of the house and the bad plumbing, which allowed the free escape of sewer-gas. In my own practice, in the family which suffered the most severely of all, four patients were seized in succession, and yet I could see no evidence of contagiousness. The family occupied a small plot of ground, not more than thirty feet by one hundred, and their occupation was to prepare for the meat-market what is known as head-cheese. They lived on the second floor of the two-story wooden house in which the work was carried on. At the time of the sickness the shop contained four hundred heads of animals from which the meat for the cheese was obtained, and evidently more or less decaying animal matter was present. The occupation and surroundings of this family afforded sufficient explanation of the fact that so many were attacked. Two workmen contracted the disease within about one week of each other, and were removed from the house. Four weeks after the commencement of the malady in the workman who was first attacked, on January 26th, one child sickened with it, and died on February 1st. Fifteen days subsequently (February 16th) a second child was attacked by it, and after a tedious sickness finally recovered. The long and irregular intervals between these cases indicate that the disease was not contracted by one from the other. The important factor in causing so severe an outbreak of cerebro-spinal fever in this family was probably the miasm produced by such an occupation in the house where the family resided, with neglect of ventilation and cleanliness.

But the strongest evidence that cerebro-spinal fever is either non-contagious, or very feebly contagious, is afforded by the fact that a large majority of the cases occur singly in families, although there is no isolation of the patients. The following are the statistics relating to this point of the cases which I have observed since cerebro-spinal fever commenced in New York, in 1871: Single cases occurred in seventy families; dual cases occurred in nine families; three cases occurred in one family, and four cases in one family. Intercourse with the sick room was unrestricted in all these families, so that children frequently went out and in, and sometimes assisted in the nursing.

The most striking example of apparent contagiousness which has come to my knowledge was related by Hirsch, and is quoted by von Ziemssen. A young man sickened with cerebro-spinal fever on February 8th. The woman who nursed him returned to her home in a neighboring village and there died of the same disease on February 26th. To her funeral mourners came from a neighboring township, and after their return home three of them died with the same disease, one within twenty-four hours, another on March 4th, and a third on the 7th.

In one instance only in my practice did the facts point to contagiousness. A boy of twelve years died of cerebro-spinal fever and was buried on Saturday or Sunday. On Monday the mother washed the linen and bed-

clothes of the boy, which had accumulated and were in a very filthy state. Two days subsequently she was attacked, and her infant soon afterward, both perishing. The state of the bedding and apartments in this house, as seen by myself, was such as would be likely to concentrate and intensify the poison, rendering it peculiarly active, for they were very dirty, and the mother, exhausted by her long and incessant watching and lack of sleep, and depressed by grief, rendered her system more liable to the disease by her self-imposed duties on the day after the funeral. One in her state of mind and body, standing for a considerable part of a day over the bed-clothes and bedding of her child, soiled by the excreta, would certainly be in a condition to contract the disease if it were in any, even the lowest degree, contagious. In the present state of our knowledge, therefore, upon this important subject, the evidence leads us to believe that with proper ventilation and cleanliness, and the suppression of anti-hygienic conditions in an infected domicile, those who are in a good state of body and mind will not contract the disease, but in the opposite conditions it is not improbable that the poison may be so intensified, and the system rendered so liable to receive the prevailing malady, through impairment of the general health and diminished resisting power, that cerebro-spinal fever may, though rarely, be communicated either by the breath of the patient, or by exhalations from his surface, or from the soiled clothing. If so, it of course possesses a low degree of contagiousness.

The occurrence of cerebro-spinal fever in certain of the lower animals is a very interesting fact, especially as the question is sometimes asked whether it may not be communicated from them to man. In the epidemic of 1811 in Vermont, according to Dr. Gallop, even the foxes seemed to be affected, so that they were killed in numbers near the dwellings of the inhabitants. Cerebro-spinal fever, previously unknown in New York City, began, as stated above, in 1871, among the horses in the large stables of the city car and stage lines, disabling many and proving very fatal, while among the people the epidemic did not properly commence till January, 1872, although a few isolated cases occurred in December of 1871. No evidence exists, so far as I am aware, that the disease was, in any instance, communicated by these animals to man. Those who had charge of the infected horses, as the veterinary surgeons and stablemen, did not contract the malady, certainly not more frequently than others who were not so exposed. Although we may admit slight contagiousness, there has probably been no well-established example of the transmission of cerebro-spinal fever from animals to man. If transmission ever do occur it is so rare that practically no account need be made of it.

In some instances we are able to discover an exciting cause. An individual, whose system is affected by the epidemic influence, may perhaps escape by a quiet and regular mode of life, but if there be any unusual excitement, or the normal functional activity of the system be seriously disturbed, an outbreak of the malady may occur. Among the exciting causes we may mention over-work and lack of sleep, fatigue, mental excitement, depressing emotions, prolonged abstinence from food followed by over-eating, and the use of indigestible and improper food. Thus in one instance among my cases, a delicate young woman, at the head of one of the departments in a well-known Broadway store, was anxious and excited, and her energies overtaxed, at the annual reopening. Within a day or two subsequently the disease began. Another patient, a boy, was seized after a day of unusual excitement and exposure, having in the meantime bathed in the Hudson when the weather was quite cool. Those children have seemed to me especially liable to be attacked who were subjected to the severe discipline of the public schools, returning home fatigued and hungry and eating heartily at a late hour. In one instance which I observed, a school girl, ten years of

age, returned from school excited and crying because she had failed in her examination and had not been promoted. In the evening, after she had closely studied her lessons, the fever began with violent headache.

Dr. Frothingham (*Amer. Med. Times*, April 30, 1864) writes as follows of the brigade in which cerebro-spinal fever occurred in the Army of the Potomac: "Under General Butterfield, a stern disciplinarian, . . . the men were drilled to the full extent of their powers, often to exhaustion. I did not at the time recognize this as the cause of the disease in question, but I learnt that in the present epidemic in Pennsylvania the attack generally follows unusual exertion and exposure to cold."

Many observers have noticed that bodily fatigue and mental depression and excitement are important factors in causing an attack of cerebro-spinal fever, when this disease is epidemic. Dr. Gallop, in his history of cerebro-spinal fever, as it occurred in Vermont in 1811, directs attention to the severity of the cases among the troops under General Dearborn, who were fatigued by marches and greatly dispirited on account of a repulse which they had sustained from the British. In one case, which occurred in my practice, a boy, six years and eleven months of age, was punished at school and came home with cheeks flushed from excitement, the excitement continuing during the ensuing night. On the following day cerebro-spinal fever began with vomiting and chilliness, the attack ending fatally on the seventeenth day. In another case, which was related to me by the mother and the physician, the patient, a bright girl, twelve years of age, of nervous temperament, and forward in her studies, had been much excited in competing for a prize in athletic exercises. In the evening of the same day a violent thunder-storm occurred, and after a severe clap she started from bed, pallid and excited, and expressed the belief that she had been struck by lightning. The disease began immediately after this, and terminated fatally on the fifth day.

Sex.—It is stated by certain writers that more males are affected than females. The statistics of hospitals and camps show this; for men subject to lives of hardship are especially liable to be attacked, but in family practice, in which a large proportion of the patients are children, the number of males and females is about equal. Thus in 105 cases, occurring chiefly in my practice but a few of them in the practice of two other physicians of this city, I find that 59 were males and 46 females. Ninety-one of these were children. In New York City, during the epidemic of 1872, 905 cases of cerebro-spinal fever were reported to the Health Board between January 1st and November 1st, and of these 484 were males and 421 females. Dr. Sanderson's statistics of the epidemic in the provinces around the Vistula, the cases being chiefly children, give also but a slight excess of males. Probably, therefore, in the same conditions and occupations of life the sexes are equally liable to contract this malady, and the excess of males is due to the fact that they lead a more irregular life, and are more subject to privations and exposures. That soldiers on duty or in barracks have been attacked while families in the vicinity escape, thus increasing the proportion of male cases, must be due to irregularities, hardships, and perhaps the lack of sanitary regulations in their mode of life.

Age.—Children, as already stated, are much more apt to contract cerebro-spinal fever than adults. The following are the statistics of the N. Y. Health Board relating to the age of the cases during the epidemic of 1872:

Under 1 year	125
From 1 to 5 years	336
From 5 to 10 years	204
From 10 to 15 years	106
From 15 to 20 years	54
From 20 to 30 years	79
Over 30 years	71
Total	975

In the cases which occurred in my own practice, and in a few cases in the practice of other physicians added to mine, I find that the ages were as follows:

Under 1 year	16
From 1 to 3 years	27
From 3 to 5 years	25
From 5 to 10 years	20
From 10 to 15 years	10
Over 15 years	15
Total	113

In my practice, therefore, three-fourths of the cases have been under the age of ten years, and the statistics of epidemics in other localities correspond with mine in giving a large excess of cases in childhood. Thus Dr. Sanderson, in examining the records of deaths in one epidemic, ascertained that two hundred and eighteen had perished under the age of fourteen years, and only seventeen above that age; and although this does not show the exact ratio of children to adults in the entire number of cases, it is evident that the children were greatly in excess.

The more advanced the age after the tenth year, the less the liability to this malady, so that very few who have passed the thirty-fifth year are attacked, and old age possesses nearly an immunity. In New York City, in which, as we have seen, cerebro-spinal fever has been occurring since 1871, only two cases have come to my knowledge which had passed the fortieth year. The age of one was forty-seven, and the other sixty-three years.

(To be continued.)

A CONTRIBUTION TO THE STUDY OF PARKINSON'S DISEASE—ANOMALOUS CASES WITHOUT TREMOR.¹

By R. W. AMIDON, A.M., M.D.,
NEW YORK.

A VERY common fault in our text-books and treatises on pathology and the practice of medicine, both general and special, is the tendency to delineate disease by the narration of *typical* cases, often to the complete exclusion of a proper notice and description of the *atypical* cases which form the bulk of one's practice.

An attempt to make all cases conform to a rule results in the parading before the student of "pathognomonic" symptoms, upon the recognition of which the case can be properly *labelled* and diagnosed; and too often, as a result, the diagnosis and not the pathological condition forms the basis of treatment.

This paper is an attempt to call the attention of the profession to anomalous cases of a very common malady, Parkinson's disease. With Charcot,² I think this a more appropriate name than paralysis agitans, for the reason that loss of power is really one of the latest symptoms to appear, and very seldom amounts to true paralysis. Charcot's words on this point are interesting: "It is, in short, strange to give the name of paralysis to an affection in which, for a long time, the muscular force is retained. The use of the word 'paralysis' is unjustifiable, because it annoys patients, and leads them to suppose they have some grave organic lesion which menaces their intellectual faculties."

"The qualifying 'agitans' added to the word 'paralysis' is not absolutely exact—at least applied to certain forms which, notwithstanding their being very striking, and the diagnosis rigorously established, lack the tremor."

Parkinson's³ definition of the disease was "involuntary tremulous motion, with lessened muscular power in

¹ An abstract of this paper was read before the American Neurological Association, June 21, 1883.

⁴ Essay on the Shaking Palsy. London, 1817.

parts not in action, and even when supported, with a propensity to bend the trunk forward, and to pass from a walking to a running pace, the senses and intellect being uninjured."

A well-developed case of Parkinson's disease presents the following symptoms: A bending forward; a rigidity of the articulations, with a tendency to fixation in flexion; tendency to propulsion; motionless attitudes; deliberate movements; slight general weakness; rhythmical tremors, which are made worse by emotions or excitement of any kind, are not made worse by voluntary movements, can generally be temporarily stopped by an effort of the will, and cease during sleep or artificial anæsthesia; an hypertrophy of the muscles affected; a peculiar deformity of the hand, fingers not flexed on themselves, but semiflexed on the hand, and thumb opposed to the index; staring and half-smiling expression; immobility of the face; speech slow and between the teeth; voice apt to be "piping"; a sensation of heat; aching pains; emotional state; fair preservation of intellect.

Diarrhœa is a very common symptom of typhoid fever, nevertheless we see cases that run their course without it, having, however, all the other symptoms of the disease. We do not create a new name for these cases but simply designate them as *atypical* cases.

As there are cases of typhoid fever without diarrhœa, so there are cases of Parkinson's disease without tremor. The first to call attention to this was Charcot, who, in a clinical lecture, November 10, 1876, presented a woman who had had for many years all the symptoms of paralysis agitans, without any tremor. In the course of his remarks on Parkinson's disease, he said: "There is an abortive form in which the tremor is so slight that it exists unnoticed by the patient, or it appears only after the lapse of three or four years, or it is entirely wanting." These remarks inspired Boucher's thesis,² which contains the narration of seven cases of Charcot's "forme fruste," three of which had no tremor at all. Only one of these is reported at length and it is taken bodily from Charcot's work.

The only other case I can find reported is in Buzzard's book.³

The recorded cases are so few I may be pardoned in presenting abstracts of them.

CASE I. (Observation of Charcot.)⁴—Female, about forty, a teacher of gymnastics in an establishment for hydrotherapy. At the age of twenty she had an attack of acute articular rheumatism, a little later a typhoid fever, and still later a pneumonia. Of late she began to have an indefinable malaise, felt stiff, was less active, and felt incapable of making quick motions. One day while mounting a ladder there came a sharp pain in the left leg with a fidgety feeling in the toes. There followed dull pains, accompanied by muscular rigidity, occurring from time to time in the nucha, loins, and shoulders. During the six months preceding her visit to Charcot the patient was annoyed by the collection of vast quantities of saliva in the mouth. (This phenomenon was checked by the administration of .004 to .005 lb. of hyoscyamine a day.) The patient's attitude is particularly stiff, the walk slow and difficult, and there is a tendency to go to the left side. Rising is slow and hesitating. Both while at rest and walking the head is immobile and slightly flexed. The features are immobile, the eyes fixed, the lips pressed. Speech is slow, weak and has a nasal twang. The arms are approximated to the body, a little rigid in semi-flexion. The fingers are slightly flexed, the wrists a little extended, and this attitude cannot be altered without an effort. There is no tremor of the hands.

The writing is free from tremor but is done only with extreme slowness and difficulty; on the execution of some movements, such as taking a handkerchief from the pocket, a few rhythmical jerks of the fingers are noticed.

CASE II. (Observation of Buzzard.)⁵—A male, aged sixty-four; a hard-working upholsterer's foreman. With the exception of typhus fever when young and a slight annoyance from gravel, he had enjoyed good health. Two years before he consulted Buzzard he found difficulty in using his knife and fork and in putting on his clothes. Four months later he began to drag his feet in walking, and gradually power was lost more and more completely in all his limbs. For a year he had been in bed, for nine months his arms and legs had been stiff, and for six months he had noticed that they tended to stay in any position they were put longer than was natural. For six months his speech had been thick. When first seen he was found helpless in bed. He had an aspect of marked mental hebetude. The speech was almost unintelligible. The face is stolid. The tongue is straight, protruded slowly, but is not tremulous. The fingers are flexed, deviate toward the ulnar side, and the distal phalanges are rather over-extended. Flexion and extension of the fingers and forearms is possible but slow. The limbs tend to remain in any position they are put. The upper extremities are emaciated, the lower flabby. The joints of the lower extremities are stiff and movements are very limited. The patella tendon-reflex is small; there is no ankle clonus, but skin reflexes are present. The right pupil is smaller than the left; both react to light.

In commenting on this case Buzzard⁶ says: "These represent the principal symptoms of a condition which is manifestly of an unusual and obscure character. I have been led to conclude that the patient represents an anomalous form of paralysis agitans, partly by the necessity of excluding other explanations, and partly by the resemblance of the patient's state to that which would be produced by an intensification of certain symptoms of shaking palsy." Again,⁷ "It is very probable that such cases as this man's are not so rare as might be thought. Looking back to past experience, I am disposed to think that I have seen several such in work-houses and hospitals, where they have been classed with cases of softening of the brain."

Axenfeld⁸ says: "In certain cases the disease is 'fruste' by the complete absence of one of the important phenomena, the tremor. Sometimes it is the rigidity of the muscles which predominates, and it gives to the body a characteristic attitude. . . . We have observed three cases of atypical paralysis agitans: in one the rigidity of the muscles of the neck was so intense that torticollis or disease of the cervico-dorsal spine was suspected; in the second case the flexion of the trunk was so marked that the body was as if folded up; the third case, aged sixty-nine, had had symptoms of Parkinson's disease for fifteen years. Fixed attitude, 'soldering' of the vertebræ, stooping position, thighs, legs, and forearms semi-flexed. Hands deformed. Expressionless, dull physiognomy. Eyes widely open, haggard, and fixed, giving an expression of constant surprise to the upper part of the face while the lower part looks sad. Saliva almost all the time dropping from the half-open mouth; lower lip pendant; slow walk; slow ideation; speech scarcely intelligible because of the difficult movement of the tongue, the muscles of which seem rigid; some dysphagia from rigidity of muscles of the pharynx and soft palate." Axenfeld adds, however, that this latter patient, when irritated or angered, had, for the time, "a tremor hardly perceptible."

I have seen in the last year four cases which I considered Charcot's "forme fruste" of Parkinson's disease.

CASE III. (Personal observation.)—A female, aged fifty-three, consulted me June 2, 1883. Her menses had ceased eleven years before. She had always worked hard at washing. Four years ago she had trouble with her daughter-in-law, and as a consequence had a falling-out with her son, of whom she was very fond. This worried her day and night, and she became sleepless over it. At that time a progressive weakness of the legs was first noticed, which is so great at times now that she cannot rise or walk about. Two years ago her voice began to fail, so that at times, now, she can only talk in a whisper. Shortness of breath and palpitation of the heart appeared about the same time. She feels very well at night, but notices that she requires less covering on the bed than formerly. She has a great deal of pain in the left axillary line and some in the right elbow. She is afraid of falling if she turns suddenly. She is annoyed much by a collection of phlegm in the throat, which is very difficult to raise. In the last year her eyesight has failed much, and it is hard work to keep her eyes open. She thinks her memory has failed; her movements are very slow, and instead of turning on the heel she takes three or four steps in reversing her course. Her posture is stooping and rigid. Her face is staring and half smiling; while speaking her lips move very little, especially the upper. Her speech is mumbly and monotonous. The grasp, as tested by the dynamometer, was weak on both sides, but the difference between the two sides was normal. The sensibility was unimpaired. The pulse was 104; vision perfect; her optic nerves were normal. She was ordered .0006 of crystallized hyoscyamine, three times a day.

July 10th.—She is sure the medicine has relieved her. Says if she never gets any better she will be satisfied. Her voice is quite strong, and she takes great pride in showing how quickly she can turn in walking.

August 17th.—Has had no medicine for two weeks. Her voice is almost extinct, and she does not walk as well as before.

She never complained of dryness of the throat or dim vision from the drug, but it invariably overcame her sleepy feeling, strengthened her voice, and improved her walk. After four months' observation the case remains in exactly the same condition; instantly relieved by hyoscyamine. Neither now nor at any previous time has there been any tremor.

CASE IV. (Personal observation.)—Male, aged sixty-two, a glazier by trade, consulted me in November, 1883. He had seen active service through the whole war and used to be of intemperate habits. He was perfectly well up to three years ago, when he lost his wife (as he says, a great shock to him), and about that time became suddenly weak and could talk very little, and sank into an apathetic condition from which he has never been aroused. He has occasional frontal headaches. His eyesight has failed, and he feels sleepy all the time. Still, he does not sleep much except at night. He has a very slow, uncertain walk, during which he stoops. All his movements are slow, particularly sitting down and rising. He has no paralysis or tremor. His face is staring and immobile, hardly expressive of anything except stupid surprise. He seldom volunteers any remarks, but in answer to questions he speaks slowly and through a half-open mouth. The voice is feeble. He has no nystagmus nor optic neuritis.

When I first saw him I considered his apathetic mental state bordering on dementia. Experimentally I ordered him .0006 of crystallized hyoscyamine twice or three times a day. When he returned in two days his whole being was changed; he walked briskly, volunteered information as to his condition in quick, distinct tones. His expression was intelligent. This improvement will be only temporary, of course, but it would hardly be expected to occur in an ordinary case of dementia.

CASE V. (Personal observation.)—A female, aged

sixty, consulted me October 5, 1883. She had always been dyspeptic, had passed the menopause at forty. Eighteen months ago she lost her daughter suddenly, and immediately a tremor set in in the right hand. The right arm and leg were weak and there was a pain about the right shoulder. The tremor was of the greatest intensity at first and gradually vanished. The pain is still sometimes present and the hand and foot remain weak. When excited now a very fine rhythmical tremor can be felt by patient in the hand. The eyesight has failed much in last three years (presbyopia); the voice has become monotonous and weaker. She has a sleepy, heavy feeling in the eyes almost all the time. Her memory is good. She has a staring immobile facies, she walks slowly, leaning forward; all her movements are slow, as is her speech, which is indistinct. The tongue points a little to the right side, the right hand is weak, the optic nerves normal. She also improved under the use of hyoscyamine, is still under observation, and so far I have never seen any tremor.

CASE VI. (Personal observation.)—A male, aged forty-eight, consulted me May 20, 1882. Does not give a clear history, but complains of general debility, nervousness, aching pains, and an inability to keep eyes open. He denied alcoholic excess. His movements were slow, and his walk stiff and stooping. His facies was immobile and dull and his eyes staring. His speech was slow and mumbly. He would sit motionless, and if left to himself his eyelids would droop and remain closed in a tremulous condition. In this state he did not sleep but yielded to an irresistible impulse to close his eyes.

TUBERCULOSIS AS PRODUCED BY SPRAYED SPUTA.¹

By LOUIS D. BROSE, M.D., PH.D.,

PROFESSOR OF ANATOMY IN THE MEDICAL COLLEGE OF EVANSVILLE, IND.; PHYSICIAN TO THE HOME FOR THE FRIENDLESS, ETC.

GENTLEMEN: my object in undertaking these experiments was to convince myself as to the infectiousness of tuberculosis. Were I asked to express my opinion previous to this research, I should have registered against anything specific in its production. This would not have been simply from literature, for I was so associated with Dr. O. C. Robinson while he conducted by inoculation his experimental researches on tuberculosis² in the Pathological Laboratory of the University of Pennsylvania, that I was almost as firm a believer in his results as he himself. The following method may be briefly stated as the manner of procedure in my investigations: Animals known not to be scrofulous or to easily acquire tuberculosis spontaneously, such as the cat and dog, were confined either in a large box, which was then placed in a room, or else they were allowed to run free in the room itself. Sputum was taken from patients known from a thorough physical examination to have phthisis.

Several of these patients have since died and the diagnosis verified by autopsy, so there can be little doubt but that the source of my material was from consumptive persons. The sputa were either placed in the bottle of an ordinary hand-spray, or else first made into a thin emulsion by admixture with an equal portion of water, and the animals sprayed during a period of five minutes for five consecutive days. As a self-protector, I invariably made use of an inhaler of borated cotton, the meshes of which were filled with powdered boric acid.

The spray was directed as far as possible toward the animal's nose. In every instance careful attention was paid to a proper and regular supply of food and water during the period of confinement, and the animals were finally killed at various dates by Scheele's hydrocyanic acid. I was aided in examining the organs macroscopi-

¹ Read before the Medical Society of the Mississippi Valley, at Indianapolis, Ind.

² See abstract Philadelphia Medical Times, vol. xii., p. 130.

cally by Dr. William Folsetter, a veterinary surgeon of much ability and a gentleman highly interested in the research.

For a better understanding, the experiments may be described under three series. The first series will include those animals sprayed with phthisical sputa and then killed before the expiration of ten days since the first spraying. April 25th a large cat was confined in a box, placed in a well-ventilated dissecting-room, and sprayed with three ounces of sputa. On the 26th and 27th sputa was again sprayed into the box. During the afternoon of the 27th she had a litter of five kittens. These were apparently at full term, and cried on my shaking the box. April 28th, besides the spray, a lot of old and very offensive sputa was poured into the box among the kittens. In the afternoon of the 29th all the kittens were found dead in the box, and the mother missing. Next day she was also found dead in the bottom of a stove in the dissecting-room.

Macroscopically and *microscopically* the lungs and other organs of the kittens were normal, well formed, and without evidence of irritation or inflammation. Death apparently occurred from inanition.

The lungs of the mother were emphysematous at the edges, slightly congested, but otherwise healthy. Spleen and liver normal in appearance. The uterus was firmly contracted, and with the exception of a congestion of the ovarian blood-vessels was without evidence of disease. Death probably occurred from septicæmia. A thorough microscopical examination did not reveal sufficient changes in any of the tissues to call them diseased.

In the second series I will place those animals sprayed with sputa, and under observation for a period of from eighteen to twenty-seven days. April 16th a grown English bull-dog bitch was confined in a box placed in a room 9 by 6 feet, and sprayed with sputa made into a thin emulsion by the addition of water. April 17th she had escaped from the box into the room, was replaced and again sprayed with some three ounces of fluid. April 18th she again escaped, and I now permitted her to remain free in the room, into which the spray was directed the three following days, besides scattering much offensive sputa over the floor. May 7th, just twenty-one days since using the first spray, the animal was killed by a hypodermic injection of Scheele's hydrocyanic acid. Death occurred within two minutes.

Autopsy.—The general body considerably emaciated. Left lung throughout is invaded by gray miliary tubercle, most numerous in the apex. The pleura covering the lung is also involved. Right lung and pleura affected in a similar manner, the tubercles being, if anything, more numerous. Bronchial glands at the root of the lungs greatly enlarged, and on section present a pigmented appearance with islets of yellow discoloration. Spleen enlarged and softened. Kidney and liver normal.

May 11th three kittens were placed in a box and kept in a well-ventilated, clean vacant room. They were sprayed on two of the five occasions by fluid exuded from the cut surface of a highly tuberculous and consolidated lung. The animals were fed on milk daily during their confinement. May 30th, after the lapse of eighteen days, one of the kittens was found dead in the box.

Autopsy.—Miliary tubercles in small numbers were present in both lungs, involving also the pleura slightly. Macroscopically the other organs were normal. June 12th the remaining two kittens were killed, and the lungs found to be highly infected. Aggregations existed in many places, forming large tubercular nodules, ready to soften and advance to the stage of cavity formation. The pleura was inflamed over the nodules and adherent to the underlying tissue. Liver softened, otherwise healthy in appearance. Spleen and kidney normal.

May 11th a strong healthy dog was placed in a room 9 by 6 feet and sprayed with the exuded matter from a phthisical lung; sputa was also scattered over the floor.

June 14th, thirty-two days since confinement, the animal was killed by hydrocyanic acid. Both lungs with the pleura contained many disseminated miliary tubercle. The spleen, liver, and kidneys were without traces of inflammation and apparently healthy.

The microscopical appearances of the viscera in this series, showing many points in common, I will describe collectively. Lungs: a lymphoid exudate occupies the lumen of many of the vesicles, and there is a tendency to thickening of the vesicle walls proper. Along with this new formation of granulation-like tissue is observed a catarrhal proliferation of the epithelium lining the air-cells. All the vesicles are not uniformly filled, as in an ordinary croupous pneumonia, but some remain empty and have their lumen encroached upon by the distended adjacent vesicles. In experiment four, the lesions approach nearest a croupous pneumonia, and some of the bronchioles on cross-section are seen filled by this same granulation element, while in the larger tubules a catarrhal proliferation is seen. Few giant-cells were observed. The bronchial glands in experiment one showed granulation tubercle. In sections of the spleen from experiment five, stained by W. D. Babcock according to Gibbe's rapid method, tubercle bacilli were detected, although no tubercular nodules were present. The other organs showed few if any abnormal changes.

The third series embraces seven control experiments. These were undertaken to further convince myself that the lesions produced were not due to simply a mechanical irritation of the inhaled particles suspended in the sputa. Animals were placed under the same conditions as those in the preceding experiments, but instead of spraying them with sputa I used the normal healthy brain of a sheep or cow, rubbed up with water into an emulsion. This, after being kept twenty-four hours, became as offensive as sputum.

June 11th.—Two kittens were confined in a box and then placed in a closed room. They were sprayed on five consecutive days with the brain of a sheep taken some two hours after death. July 5th, twenty-four days since using the first spray, they were anesthetized and killed.

Macroscopically and *microscopically* there were no perceptible changes or signs of irritation in either the lungs, pleura, liver, or kidneys. August 18th five kittens were placed in a room 16 by 12 feet and sprayed with the brain of a cow. They were fed daily upon milk. Besides the spraying, quantities of brain matter were scattered over the floor. August 29th three of the kittens were found dead. A thorough examination did not reveal the presence of tubercle in any of the organs, death resulting probably from heat exhaustion, as the windows were kept closed and the temperature of the room was very high. September 8th, twenty-one days since the first spraying, the two remaining kittens were killed.

Autopsy.—Lungs crepitate, are perfectly healthy and normal in color; spleen and liver normal in size. Microscopically the healthy appearances noted at the autopsy are corroborated.

The first to investigate this disease by experimental observation was Villemain, of France, who in 1867 inoculated rabbits with tubercular matter, and established the fact that in the lower animals morbid changes, constant in their anatomical appearances and development, followed; that these changes were to be regarded as constituting the disease tuberculosis. Then followed Waldenburg in the same year¹ with a paper wherein he states that in some animals, especially the rabbit, the inoculation of finely powdered innocuous substances also gave rise to tuberculosis. Cohnheim and Frankel, in two repetitions of Waldenburg's work,² arrive at a different conclusion. In their first series, conducted in the Pathological Institute in Berlin, they confirmed his results;

¹ Treatise on Tuberculosis, Phthisis, and Scrofulosis.

² Virchow's Archiv, vol. xlv.

while in the second series, conducted in another locality, they could only produce the anatomical changes of tuberculosis by the inoculation of tubercular matter itself. They now regard the disease as infectious, and explain their first result as due not to the inoculation but rather to infection through other tuberculous animals in the same institution. These experiments have since been repeated by a number of observers, and with various results. Those who hold that tuberculosis alone follows the inoculation of tuberculous matter contradict the negative party by calling their experiments unreliable and open to the errors of either the admixture of tubercular with indifferent material or else spontaneously acquired tuberculosis. The first to produce the disease experimentally by inhalation was Tappenier, in 1877. Unfortunately I have not been able to see his original paper, but from an editorial in the *Medical News*, May 5, 1883, learn that his results closely coincide with my own. In his first four experiments he used sputa from fresh tubercular cavities rubbed up with a good deal of water into a thin emulsion, and permitted dogs to inhale it from a steam atomizer, the animals being enclosed in airy cages and protected from dust. The exact method and conditions of the remaining experiments he does not describe, but in all he records 31 inhalation experiments with dogs, of which 18 were true infection experiments with tubercular sputum, 8 control experiments with other substances, and 5 experiments with tubercular sputum with a view to determining the period of incubation. In all the 18 experiments the results were positive. In 17 there was tubercle in both lungs and pleura; 4 times in addition to the tubercles in the lungs there were tubercular nodules in the kidneys, spleen, and liver, and in 3 instances in addition to the tuberculosis of the lungs there were also cheesy foci and small cavities. In one instance only there was typical desquamative pneumonia. Of the 8 control experiments, 2 were made with calves' brain, treated in the same way as the tubercular sputum; 2 with the suppurative expectoration of a chronic bronchitic patient, and 4 with cheesy pus from lymphatic glands. All the 8 control experiments were completely negative, there being no trace either of tubercular nodules or of irritation of the lung by the finely divided particles. In the 5 control experiments, in which sputum from tubercular cavities was inhaled, the animals were killed in from ten to twenty days after the beginning of the inhalation, and none of them showed any trace of tuberculosis or other symptoms of irritation of the lung, although large quantities of sputum had been inhaled.

From these experiments he concludes that the period of incubation cannot be less than twenty days, and since, also, all the dogs killed in more than twenty-four days from the beginning of the experiments, excepting the single one with desquamative pneumonia, were tuberculous, it would appear that the inoculation effects developed themselves within the short period of four days. My own success in five infection experiments fully corroborates his eighteen positive results. Furthermore, my observation is that the more concentrated the spray and the greater the saturation of the inhaled atmosphere, the greater the degree of infection and development of tubercle in the animal under experiment. Our control experiments are wholly in unison; in neither case was there a trace of inflammation or irritation in the viscera of the experimented animals.

Spina,¹ in publishing his studies on tuberculosis, quotes a Dr. Knauff as having obtained true tubercles in the lungs of animals by having them inhale coal-dust; also a Dr. Inis as producing the same lesions by inhalation of stone-dust and lamp-black. That certain morbid appearances may thus be produced in the lung I think will be conceded by all when it is remembered that in granite-masons, coal-miners, knife-grinders, and others exposed to the inhalation of mechanical irritants, bronchial affec-

tions occur, often attended with fibroid induration and disease of the lung itself closely resembling pulmonary consumption. But that such inflammatory nodules are true tubercle is a matter of much doubt. Dr. A. Weichselbaum,² who has lately experimented upon this subject, concludes that the inhalation of other organized though non-tuberculous substances may produce nodules in the lungs, which may, it is true, have the external signs of tubercles, but which cannot positively be identified as tubercles. The inhalation of tuberculous sputum produces in dogs a true miliary tuberculosis of the lungs and frequently of other organs, but which seems to have no progressive character. My friend and former teacher, Dr. Henry F. Formad, of Philadelphia,³ offers to explain the success of all inhalation experiments on the ground that the epithelium lining the air-vesicles approaches very closely in histological character the lining of the serous membranes—in fact it is considered by some to be endothelial. Now, according to his paper true tuberculosis can be produced even in non-scorfulous animals through simple injuries of serous membranes. Hence the spray simply acts in the capacity of setting up an inflammatory irritation, and in consequence of a too rapid absorption of the inflammatory exudate, we have here a blocking up of the lymph spaces of the connective tissue by the fibrin and molecular debris which was suspended in the absorbed serum. From extended researches he announces that the predisposition to tuberculosis in some men and animals, the so-called scorfulous habit, lies in the anatomy of the connective tissue of the individual, the peculiarity being a narrowness of the lymph spaces and their partial obliteration by cellular elements; only beings with such anomalous structure of connective tissue can have primary tuberculosis, and such animals invariably do become tuberculous from any injury resulting in inflammation, or from repeated injuries.

Scorfulous beings can have no other than a tuberculous inflammation, although it may remain local and harmless. Non-scorfulous men or animals may acquire the predisposition to tuberculosis through malnutrition and confinement, the latter bringing on the above-mentioned anatomical peculiarities. No special virus or external etiological influences are necessary to cause tubercular disease other than those which ordinarily produce inflammation, and scorfulous beings will not become tuberculous unless local inflammation is set up.

If these views be correct, why did Tappenier in eighteen consecutive cases, and my own five cases of true infection experiments alone result in positive success?

The same irritation surely existed in the sputum used on those animals killed before the expiration of fifteen days, and yet in not a single instance did inflammation occur with subsequent blocking up of the lymph spaces. Again, the control experiments were certainly not without some irritating influence, and yet in no instance was there discovered a sign of tubercle in the lungs or pleura after death. Under these circumstances I feel justified in presenting the following conclusions:

First.—That tuberculosis may follow the inhalation of air-carrying particles of sputa from phthisical patients.

Second.—The breath and saliva of consumptive persons, being thus contaminated, are liable to originate, either through kissing or by direct inhalation through close contact, the same disease in a healthy person; the greater the concentration of the breath inhaled the greater the danger.

Third.—Since the same sputa in animals killed under ten days produced no disease, and since the healthy brain of other animals produced no disease, in cats even when under observation for a period longer than twenty days, while true tuberculosis always followed (in five of my own cases) the inhalation of tuberculous sputa in animals between eighteen and thirty days after the first spraying, I feel warranted in inferring that, in the last

³ Philadelphia Medical Times, November 18, 1882.

instance there was something specific in the inhaled spray requiring certain development before originating the infectious disease, tuberculosis. That it was alone the *tubercle bacillus of Koch*, I have not claimed. My own opinion regarding the origin of tuberculosis, formed from this research and a no inconsiderable clinical experience with the disease, is that, like diphtheria, it is ordinarily determined by certain peculiarities and susceptibilities in individuals, together with the presence of a specific principle. Now when a person who has this peculiarity of weak lungs, or in other words one in whom bronchial and catarrhal troubles are easily excited, has superadded the infection of tuberculosis, let it be in a minimum amount, we have arising true consumption running through its various stages. Even healthy persons can thus be infected when the specific matter is inhaled in large quantities, just as the poison in other infectious diseases will certainly produce these same diseases when inoculated in concentrated quantities in persons who would otherwise escape. The reason why we have acute disseminated miliary tuberculosis in one case, and a catarrhal phthisis in another, will depend upon the susceptibility of the individual to catarrhal cell-proliferation and whether the specific principle was superadded to an already existing catarrh, in which case the specific principle would reproduce itself easiest at the seat of tissue necrobiosis. If, on the contrary, there existed a proclivity against catarrhal processes, and the person was infected with a concentrated dose, so to speak, of the specific principle of tubercle, there might arise a disseminated miliary tuberculosis.

GOITRE—EXCISION—CURE.

By JOHN A. WYETH, M.D.,

SURGEON TO MT. SINAI AND ST. ELIZABETH HOSPITALS; PROFESSOR OF SURGERY IN THE NEW YORK POLYCLINIC.

SEPTEMBER, 1883.—E. H.—, female, aged sixteen, blonde, born in Virginia; resided there six months, six years in Pennsylvania, four in Washington City, and the last six years in Brooklyn, N. Y. Mother living and in good health. Father living; has had asthma, but for three years past has had no attacks. Three sisters living and healthy; one brother still-born.

Patient is in good health; menstruation, which began at fifteen, regular; great hypertrophy of right thyroid body; had scarlatina four years ago, accompanied with and followed by sore throat. Noticed the tumor at this time, which grew slowly for two years, then more rapidly, and in the last six months its growth became alarming.

October 10th.—Operation before the surgical class of the Polyclinic. Ether; incision over middle of tumor, parallel with and to right of median line; muscles pulled aside; all tissues divided between two of my hæmostatic forceps. Isthmus tied with elastic ligature, then superior and inferior thyroid arteries with antiseptic catgut, and tumor turned out. Operation one hour. Hemorrhage insignificant.

Tumor was about five inches long and twelve inches in transverse circumference. Wound washed out with hydrarg. chlorid. corrosiv., 1 to 2,000, and sewed up with silk. Drainage-tube and end of elastic ligature passed out of the most dependent portion. Carbolyzed gauze and borated cotton dressing.

October 11th.—Temperature, 101.8° F., declined gradually to normal on 21st. Wound healed per primam (excepting drain-hole). Elastic ligature came away on the 18th, and patient discharged cured on October 31st.

In THE RECORD for January 28, 1882, p. 94, I have reported one other operation for goitre by myself, and added several more, to which any one interested in this subject is referred.

RECORD OF THE YELLOW FEVER IN THE UNITED STATES—1668-1883.

In looking up the history of the occurrence of yellow fever in the United States, we find that the annual reports of the Surgeon-General of the U. S. Marine Hospital Service and Public Health Bulletin published by that service contain records covering a period of over two hundred years, the first cases appearing in New York (City) in 1668. Briefly, the record is as follows:

New York (City) in 1668, 1702-32-41-42-43-45-47-48-62-90-91-92-93-94-95-96-97-98-99, 1800-01-02-03-05-06-07-08-09-10-15-16-17-18-19-20-21-22-23-24-25-26-27-28-29-30-32-33-34-35-38-39-43-44-46-47-48-52-53-54-55-72 (in quarantine)-73 (in quarantine and Marine Hospital wards, N. Y., and more or less cases in quarantine or Marine Hospital every year since).

New York (State)—Albany, 1746-98; Bay Ridge, L. I., 1856; Brooklyn, 1809-23-56; Brooklyn Navy Yard, 1878; Catskill, 1743-94 and 1803; Governor's Island, 1856-70; Gowanus, 1856; Greenfield, 1798; Huntington, 1795-98; Queensborough, 1801; Red Hook, 1856; Stapleton, 1848; Yellow Hook, 1856; Tompkinsville, 1848; West Point, 1804, and West Neck, 1795.

Alabama—Mobile, 1705-56-66, 1819-21-22-24-25-27-28-29-37-38-39-41-42-43-44-47-48-49-51-53-54-58-67-70-73-78; Blakely, 1822; Cahawba, 1853; Citronville, 1853; Decatur, 1878; Dog River cotton factory (five miles from Mobile), 1853; Demopolis, 1853; Fort Claiborne, 1819; Fort Morgan, 1867; Fort St. Stephens, 1819; Fulton, 1853; Hollywood, 1853; Leighton, 1878; Montgomery, 1853-54-55-73; Pollard, 1873; Selma, 1853; Spring Hill, 1853.

Arkansas—Columbia, 1853; Fort Smith, 1823; Grand Lake, 1853; Little Rock, 1873; Napoleon, 1853.

Connecticut—Chatham, 1796; Hartford, 1798, 1800; Knowles Landing, 1796; Middletown, 1820; New Haven, 1743-94, 1803-04-05-19; New London, 1798; Norwalk, 1798; Stamford, 1745; Stonington, 1798.

Delaware—Christiana, 1798; Duck Creek, 1798; New Castle, 1798; Wilmington, 1798.

Florida—Pensacola, 1764-65, 1811-22-25-27-34-39-41-42-43-44-45-46-47-48-53-54-58-63-67-73-82; Apalachicola, 1826; Barrancas, 1875; Cedar Key, 1871; Fernandina, 1877; Gainesville, 1871; Jacksonville, 1857; Key West, 1824-29-41-53-54-62-64-65-67-69-75-78; Milton, 1853-55; St. Augustine, 1807-21-38-39-41; St. Joseph, 1841; Suwanee, 1836; Tampa, 1839-53-71; Tortugas, 1862-67.

Georgia—Savannah, 1807-08-19-20-27-52-53-54-58-76; Augusta, 1839-54; Bainbridge, 1873; Brunswick, 1876; St. Mary's, 1808.

Indiana—Indianapolis, 1878 (refugee).

Illinois—Cairo, 1873-78.

Kentucky—Louisville, 1873-78; Hickman, 1878; Covington, 1878 (refugee).

Louisiana—New Orleans, 1769-91-93-94-95-96-97-99, 1800-01-02-04-09-11-12-17-18-19-20-22-23-24-25-27-28-29-30-31-32-33-34-35-36-37-38-39-40-41-42-43-44-45-46-47-48-49-50-51-52-53-54-55-56-57-58-62-63-64-67-70-71-72-73-75-78 (and more or less cases in quarantine every year since); Alexandria, 1819-22-27-31-37-39-47-53-54-55; Algiers, 1847-53-58; Ascension, 1823; Baton Rouge, 1817-19-22-27-29-37-43-47-58-78; Bay of St. Louis, 1820-30-78; Bayou Sara, 1847-53; Bonsecour, 1878; Burat Settlement, 1854; Carrollton, 1847-55; Centreville, 1853-55; Clinton, 1853-78; Covington, 1847; Clouterville, 1853-54; Delphi, 1878; Delta, 1878; Donaldsonville, 1827-39; Franklin, 1853-54; Fish River, 1878; Gretna, 1858; Greenwood, 1873; Hudson, 1878; Iberville, 1847; Jeanerretts, 1854; Jesuit's Bend, 1854; Lafayette, 1847; Lake Providence, 1853; Maudville, 1847; McDonoughville, 1858; Morgan City, 1878; Natchitoches, 1839; New Iberia, 1867-70; Opelousas, 1829-37-39-42-53-

67; New Orleans (a small settlement below New Orleans proper), 1854; Pattersonville, 1853-54-55; Plaquemine, 1837-39-47-53-58-78; Point a la Hache, 1854; Port Barre, 1870; Port Eads, 1878; Port Hudson, 1839-41-43-73; St. Francisville, 1811; Feliciana Parish, 1817-19-23-27-29-39-43-46-48-53; St. John Baptiste, 1853; St. Martinsville, 1839; St. Mary's Parish, 1854; Shreveport, 1853-73; South Pass, 1878; Southwest Pass, 1878; Thibodeau, 1853-54-56; Trenton, 1853; Vidalia, 1853; Ville Platte, 1870; Washington, 1837-39-52-53-54-67.

Maryland—Baltimore, 1794-95-97-98-99, 1800-01-02-05-19-20-21-22-68-79 (in quarantine); West River, near Annapolis, 1805.

Massachusetts—Boston, 1691-93, 1795-96-98, 1800-02-05-19-58-78 (in Marine Hospital); Holliston, 1741; Nantucket, 1763; New Bedford, 1800-01; Newburyport, 1796; Salem, 1798.

Mississippi—Biloxi, 1702, 1839-47-53-58-78; Bolton, 1878; Brandon, 1853-54; Canton, 1855-78; Clifton, 1853; Cooper's Wells, 1855; Crystal Springs, 1878; Dry Grove, 1878; Friar's Point, 1878; Grand Gulf, 1853; Greenwood, 1853; Jackson, 1853-54-78; Greenville, 1878; Granada, 1878; Handsborough, 1878; Hernando, 1878; Holly Springs, 1878; Lake, 1878; Lebanon Church, 1878; McComb, 1878; Meridian, 1878; Mississippi City, 1878; Moscow, 1878; Natchez, 1817-19-23-25-27-29-37-39-44-48-53-55-58; Ocean Springs, 1878; Pascagoula, 1847-53-78; Pass Christian, 1847-53-55-58-78; Petit Gulf, 1853 (thirty plantations near Petit Gulf); Rodney, 1829-43-47-53; Osyka, 1878; Port Gibson, 1878; Scranton, 1878; Shieldsborough, 1820-29-39; Spring Hill, 1878; Vicksburg, 1839-41-47-58-71-78; Washington, 1825; Water Valley, 1878; Whitzell's Landing, 1817; Woodville, 1844-52-53-55-58; Yazoo City, 1853.

Missouri—St. Louis, 1854-55-78 (refugees); New Design (twenty miles below St. Louis), 1797.

New Hampshire—Portsmouth, 1798.

New Jersey—Bridgeton, 1798; Gloucester, 1805; Perth Amboy, 1811; Port Elizabeth, 1798; Woodbury, 1798.

North Carolina—Beaufort, 1854-64-71; New Berne, 1799, 1864; Smithville, 1862; Washington, 1800; Wilmington, 1796, 1800-21.

Ohio—Cincinnati, 1871-73-78; Gallipolis, 1796, 1878; Dayton, 1878 (refugee).

Pennsylvania—Philadelphia, 1695-99, 1732-41-42-43-44-47-62-91-93-94-96-97-98-99, 1800-01-02-03-05-07-09-10-11-13-14-15-16-19-20-53-54-70-78 (refugee); Pittsburg, 1878 (refugee); Bald Eagle, 1799; Chester, 1798; Chester County, 1805; Kensington, 1793; Lisburn, 1803; Marcus Hook, 1798; Niltany, 1799; Southwark, 1793.

Rhode Island—Block Island, 1801; Bristol, 1795-96-97; Newport, 1806; Providence, 1794-95-97, 1800-05; Westerly, 1798, 1805.

South Carolina—Charleston, 1699, 1703-28-32-34-39-45-48-53-55-61-62-68-70-92-94-95-96-97-98-99, 1800-02-03-04-05-07-12-17-19-22-24-25-27-28-30-34-35-38-39-40-41-43-49-52-54-56-57-58-62-64-71; Beaufort, 1871; Columbia, 1854; Fort Moultrie, 1852-58; Georgetown, 1854; Hilton Head, 1862; Mount Pleasant, 1817-48-52-54-56-57.

Tennessee—Memphis, 1853-55-66-73-78; Brownsville, 1878; Chattanooga, 1878; Germantown, 1878; Grand Junction, 1878; Mason, 1878; Nashville, 1878; Milan, 1878; Paris, 1878.

Texas—Galveston, 1839-44-47-53-54-58-59-64-66-67; Alleytown, 1867; Anderson, 1867; Austin, 1867; Bastrop, 1867; Beaumont, 1863; Belleville, 1855; Brazoria, 1859; Brenham, 1867; Brownsville, 1853-58-62-82; Calvert, 1867-73; Chapel Hill, 1867; Columbus, 1873; Columbia, 1833; Corsicana, 1873; Corpus Christi, 1862-67-73; Cypress City, 1853-59; Danville, 1867; Edinburg, 1859; Goliad, 1867; Harrisburg, 1867;

Hempstead, 1867; Hockley, 1853; Houston, 1839-44-47-48-53-54-58-59-64-70; Huntsville, 1867; Independence, 1867; Indianola, 1852-53-58-59-62-67; La Grange, 1867; Liberty, 1867; Liverpool, 1853; Matagoras, 1862-63; Millican, 1864-67; Navasota, 1867; Oldtown, 1867; Port Lavacca, 1867; Point Isabel, 1882; Richmond, 1853-59; Rio Grande City, 1867; Sabine City, 1863; Saluria, 1853; Sugarland, 1859; Victoria, 1867.

Virginia—Norfolk, 1747-94-95-96-97-98-99, 1800-01-02-03-04-05-21-26-52-54-55; Alexandria, 1803; City Point, 1798; Gosport, 1855; Hampton Roads, 1869; Petersburg, 1708; Portsmouth, 1852-54-55; Richmond, 1806 (78 refugees); Scott's Creek, 1855; Winchester, 1804.

Since the reorganization of the service in 1871-73 (when it was placed under a medical head), a large number of valuable papers on the subject of yellow fever have appeared in the reports. In the Annual Report of 1873, Dr. J. M. Toner, of Washington, D. C., contributed a paper entitled "The Distribution and Natural History of Yellow Fever as it has Occurred at Different Times in the United States." In the same Report may be found yellow fever notes by the late Surgeon-General Woodworth and Surgeons Hebersmith, Orsamus Smith, P. H. Bailhache, Dr. J. S. Mosher, Deputy Health Officer of the port of New York, Dr. G. B. Thornton (at that time in charge of Marine Hospital patients, Memphis, Tenn.), Dr. O. L. Crampton (in charge of Marine Hospital patients, Mobile, Ala.), and Dr. H. Wardner (in charge of Marine Hospital patients, at Cairo, Ill.).

In the Report of 1874 is a paper by Dr. James S. Herron, of Pensacola (Surgeon in charge of Marine Hospital patients at that time), giving the history of yellow fever at Pensacola in 1874, and another by Dr. Frank W. Riley (late Surgeon of the Marine Hospital Service), giving a history of the epidemic in 1873 at Pensacola, New Orleans, Memphis, Shreveport, Mobile, Cairo, Ill., Greenwood, La., Calvert, Tex., Montgomery, Ala., Fort Barrancas and Jefferson, Fla. This Report was prepared under the supervision of the late Surgeon-General Woodworth, by direction of the Secretary of the Treasury, in compliance with the following preamble and resolution of Congress:

Whereas, Yellow fever has again prevailed during the past year as an epidemic of frightful severity in some of the cities and towns of the United States, paralyzing trade and commerce throughout large sections of country by impeding travel and menacing neighboring communities; and

Whereas, Many cities equally exposed with those which suffered most severely escaped with slight mortality, indicating that certain conditions and measures may control or arrest the spread of the epidemic; and

Whereas, The history of the disease tends to show that it is almost uniformly introduced into the United States by seamen already infected with the contagion, or arriving from ports where the disease exists; and

Whereas, The United States Marine Hospital Service, through its medical officers at the ports where the epidemic prevailed, was enabled to become familiar with the course of the disease, the conditions favorable to its introduction and progress, and the measures which were successful in controlling or checking it; therefore

Resolved, That the Secretary of the Treasury be, and hereby is, directed to instruct the Supervising Surgeon of the Marine Hospital Service to prepare or cause to be prepared, from the reports and observations of the Marine Hospital surgeons and from other available sources, a brief and succinct history of the yellow fever epidemic of 1873 as it prevailed at the various ports of the United States, with especial reference to details of prevention and hygiene; and transmit the same to the Senate at the earliest day practicable.

This Report is very complete and is accompanied by an outline map of the epidemic.

The Report of 1875-76 contains a history with map of the disease at Key West in 1875, by Surgeon Murray; at Barrancas, for the same year, by Dr. J. S. Herron (at that time in charge of Marine Hospital patients); in New Orleans and Pascagoula for the same year, by Surgeon Vansant.

The Report of 1876-77 contains a history of the disease in Savannah and Brunswick, Ga., in 1876, by Assistant Surgeon (now Surgeon) Henry Smith; in Savannah for the same year by Assistant Surgeon George H. Stone; in Fernandina, Fla., by Surgeon Murray; and the Marine Hospital at Boston by Surgeon (now Surgeon-General) John B. Hamilton.

The Report of 1878-79 contains a history of the disease of 1878 at Gallipolis, O., on the steamer H. D. Porter and cities and towns at which this infected vessel stopped, by Surgeon W. H. Long; at St. Louis, by Surgeon Wyman; at Cairo, Ill., by Assistant Surgeons Waldo, O'Reilly, and Keyes. The Bulletin of the Public Health, published during this epidemic by the Marine Hospital Service, gives the progress of the disease at New Orleans and Memphis, as well as all other places in the United States, besides containing a record of the devastating plague in Southern Russia, with maps of infected districts; also record of Asiatic cholera in the Eastern hemisphere, and copy of regulations issued by this Government to prevent the introduction of contagious and infectious diseases.

The Reports of 1882 give a portion of the history of the epidemic at Brownsville and Point Isabel, Tex., and Pensacola, Fla., by Surgeon Murray and Acting Assistant Surgeon White, and we understand that the Report for 1883, now in the hands of the printer, will conclude the history of the epidemic of 1882 in Texas and Florida, and give a statement of the epidemic of 1883 up to the date of its appearance in the Naval Reservation near Pensacola and the means employed to prevent its spread during the current season.

Reports of Hospitals.

PRESBYTERIAN HOSPITAL, NEW YORK.

SERVICE OF DR. F. A. BURRALL.*

(Reported by ALPHEUS FREEMAN, Jr., M.D., House Physician.)

CASES OF INSOLATION WITH HIGH TEMPERATURES.

THE following histories of three cases of insolation occurring at the Presbyterian Hospital are interesting for the high temperatures exhibited.

CASE I.—On June 13, 1883, an unknown man was brought to the hospital, having become prostrated by the heat while doing laboring work in the upper part of the city. He was admitted at 11 A.M., unconscious, with the radial pulse imperceptible, respirations twenty-eight to the minute and very shallow, and a rectal temperature of 113.5° F. There was marked pallor of the face, and the eyes were turned up, with the pupils equal, contracted, and not responsive to light. No further examination was made, but he was immediately placed on a Kibbee cot and wrapped in a sheet, while ice was applied to the head, mustard to precordial region, and hot bottles to the feet. This cot is so constructed that the patient lies upon a support of netting, with a trough placed beneath it. After wetting the sheet with water at about 65° F., ice-water was poured over the surface of the body and a hypodermic of ℥ xxx. of equal parts of whiskey and ether was administered at intervals of five minutes.

At 11.30 A.M. a very thready pulse at the wrist could be felt, beating at the rate of 188 to the minute, and after this treatment had been continued for an hour longer, it was found that the temperature had fallen to 106°. He was then rubbed dry and wrapped in blankets. Hypodermics of whiskey, ℥ xxx., were given

every ten minutes, and one ℥ xx. dose of tinct. digitalis was administered. Soon after this the pulse became stronger, the respirations deeper, the pallor disappeared, and the pupils dilated. The temperature continued to fall, and at 1 P.M. was 103.5°, with pulse 155 and respiration 28. At this time he had a loose fecal movement, and soon after vomited a thick yellowish material. Whiskey, 5 i., was introduced by the rectum, and retained. The condition of the pupils frequently changed; sometimes they were unequal, or contracted, or widely dilated. At 1.30 P.M. the temperature was 99.5°. Soon after this slight convulsive movements began to appear in the upper and lower extremities, and the patient occasionally would utter loud inarticulate sounds. The convulsions increased in severity, and the pulse grew weaker, while the pupils dilated widely. Dry cups were applied along the spine, but in a short time he became so violent that restraint was necessary. The breathing becoming very shallow, inhalation of oxygen was resorted to for fifteen minutes, and appeared to deepen the respirations. The patient also swallowed whiskey, 3 ij., but did not retain it. At 4 P.M., the temperature having risen to 105°, water was again poured over the body, but in ten minutes it rose to 106°, after which it began to fall, and in half an hour stood at 103°, when he was removed from the cot and wrapped in blankets. Violent general tonic and clonic spasms occurred every few seconds, and the radial pulse, rapid and feeble, finally became inappreciable. Whiskey, 3 ij., was given by enema, and retained, and the inhalation of oxygen was again resorted to, and improved the breathing slightly. At 5 P.M. a very small, soft, rapid pulse could be felt. The pupils were dilated and distinctly oval in shape vertically, but did not respond to light. The superficial reflexes were absent. All this time the convulsions continued and followed each other more rapidly and with undiminished violence, while during the intervals between the clonic spasms the muscles remained in a state of rigidity. Finally, the pulse disappeared and the face became cyanosed. By a convulsive movement the body was thrown forward, immediately after which he fell back and died at 6 P.M.

Autopsy twenty-two hours after death.—The muscle of the heart was unusually dark, red, and firm. Both lungs were very dark in color, almost black. When cut open they were found to be intensely congested and slightly oedematous. Both kidneys were moderately congested. The cut section of the liver showed numerous light-colored anæmic spots, as if the blood had suddenly been sucked from the liver and abdominal viscera to fill the lungs. The meninges of the spinal cord and brain were slightly congested; the brain itself was moderately congested.

The primary cause of death was the heat; the secondary or immediate, congestion of the lungs, with heart-failure.

CASE II.—P. Mc—, aged twenty; single; Ireland; laborer; was admitted on June 7, 1883, at 5.30 P.M., unconscious, and having general convulsions and frequent attacks of vomiting. The pulse was 166 and feeble, respiration 36, and temperature 109° in the rectum. Both pupils were contracted, but otherwise normal. He was placed on the Kibbee cot, with an ice-cap applied to the head, and ℥ lx. of equal parts of whiskey and ether were administered hypodermically. Ice-water was applied to the surface of the body, but in half an hour the temperature had risen to 109.5°, after which it began to fall and in an hour had reached 106.3°, when the convulsions ceased. This treatment being continued for forty minutes longer, the temperature had fallen to 101° and the cold-water applications were discontinued. He still remained unconscious, and in about five minutes the convulsive movements began to reappear. Chloral hydrate, gr. x., and tinct. digitalis, ℥ xxx., were given hypodermically, but had no apparent effect upon the convulsions. An hour later the temperature had risen to 106.8°, and

the cold-water treatment was again resorted to. Whiskey, ℥ xxx. hypodermically, was given every twenty minutes, and in one hour the temperature fell to 101.2°. He continued to improve steadily after this, and consciousness gradually returned. The urine showed a trace of albumen, but was otherwise normal. During the next four days the temperature never rose above 101.5°, and on the fifth day he sat up. From this time he continued up and about, only complaining of occasional vertigo, which lasted for two weeks, at which time his general health was excellent and he had no complaint whatever.

CASE III.—T. M—, aged fifty-six; married; Ireland; laborer; was admitted to the hospital on July 17, 1883, at 12.50 P.M., in an unconscious state. The pulse was 128, full and soft, respiration 28 and stertorous, and the rectal temperature 109°. Whiskey, ℥ lx., and tinct. digitalis, ℥ xxx., were administered, and by the use of ice-water the temperature was reduced in fifty minutes to 101°. Soon after, slight twitchings were noticed in the upper and lower extremities and he began to groan loudly with each respiration; vomiting of a greenish matter occurred twice, and the temperature slowly rose to 102.2°. Improvement followed after this, and in four and a half hours from the time of admission he became conscious. From this time no rise of temperature took place, but his intellect was considerably impaired. On the second day a diarrhoea set in. The tongue became brown and dry, and delirium came on at night. The next day he became so violent that restraint was necessary, but no rise of temperature occurred. The urine presented the same characters as in the previous case. He slowly improved after this, and by August 1st was in excellent condition, both mentally and physically.

These thermometrical observations were made by an accurate instrument. In all the cases of sunstroke treated here during this summer, the temperature has readily responded to the application of cold, but showed a tendency to rise again for a time. The convulsions have not easily yielded to treatment, and seemed to favor heart-failure by producing exhaustion. Medication by the mouth has appeared useless, owing to the intolerance of the stomach.

With few exceptions the patients were natives of Ireland, who had only been a few weeks in this city.

Progress of Medical Science.

ADULTERATIONS OF LARD.—The recent investigation before the Chicago Board of Trade as to the purity of certain specimens of lard has developed several facts which are of interest to the general public as well as to scientists. The present position of science, chemical and microscopical, on the subject of lard adulteration has been defined and demonstrated by an array of experts such as has rarely if ever been equalled in this country either as to number or quality. First, it has been demonstrated incontestably that chemistry is at present unable to distinguish the fat of the hog from that of the ox, and is therefore impotent to detect an adulteration of lard when that adulteration consists of beef tallow. Second, it has been demonstrated that with the microscope a competent observer can readily distinguish beef fat from hog fat, and can accordingly detect an adulteration of lard with tallow. This fact is, to the best of the writer's knowledge, entirely new to science. Third, it has been shown that in the attempt to detect cotton-seed oil when mixed with lard, the chemist and the microscopist exchange their former rôles; for chemistry has an infallible method for recognizing and detecting cotton-seed oil even when mixed with other fats, while the microscope cannot distinguish this substance from pure lard.

Several facts of interest to the public were incidentally developed in the course of the investigation. Thus it is acknowledged by manufacturers that while the article

called "prime steam lard" is what it purports to be—pure hog fat—yet several other brands of lard are regularly adulterated; for example, the substance which is by a refinement of irony designated "refined lard" is confessedly a mixture of lard with other fats, animal or vegetable. The occasion which led to this memorable investigation was a charge that a certain quantity of lard which had been sold upon the Board of Trade as "prime steam lard"—that is, as pure hog fat—was adulterated with tallow and with cotton-seed oil. The purchaser of this lard—amounting to some five hundred thousand tierces—sought to recover damages before the directors of the Board of Trade.

The evidence in support of the complaint consisted of two parts: First, the testimony of certain discharged employes of the firm accused of the adulteration (Fowler Bros.). These men, who, as was shown during the trial, were paid for their evidence, swore to the intentional admixture of foreign substances with the lard during the process of manufacture. The second part of the evidence for the prosecution—the only portion of scientific interest—consisted in the testimony of four chemists, to the effect that they had detected (1) tallow and (2) cotton-seed oil in the lard manufactured and sold by Fowler Bros. Their test for detecting tallow in lard is the so-called stearine test, and is based upon the hypothesis that tallow (beef fat) contains a larger percentage of stearine than lard does. According to these chemists pure lard contains one to two per cent. of stearine, while tallow has a much larger percentage. The chemists for the defence, Professors Remsen, of the Johns Hopkins University, Baltimore; Doremus, Witthaus, and Habirshaw, of New York; Sharples, of Boston; Haines, Rose, Hayes, and Tilley, of Chicago, all agreed, as the result of their personal experience, that the stearine test was utterly unreliable in distinguishing tallow from lard. This unreliability is due to the fact that it is impossible to determine the average quantity of stearine in either lard or tallow, so as to detect a constant difference. Profs. Doremus, Sharples, and Haines, in examining different specimens of pure lard, obtained results in the quantity of stearine varying as much as eight hundred per cent. These gentlemen testify that they weighed out at the same time two samples of pure lard from the same can, placed them in two flasks of equal size, and treated them in exactly the same manner, and yet obtained from the one about eight times as much stearine as from the other. They further found that while pure lard yields on an average (by the process of the chemists for the prosecution) about *three and four-tenths* per cent. of stearine, yet a mixture containing ninety per cent. of that same lard with ten per cent. of tallow gives only *two and one-half* per cent. of stearine. Profs. Remsen and Witthaus demonstrated by an elaborate series of experiments that the addition of even forty per cent. of tallow to pure lard, instead of increasing the amount of stearine extracted from it by this process, actually diminished this amount very materially. Even in their own hands the processes used by the chemists for the prosecution yield results so discordant as to prove their absolute unreliability. Thus from the same sample of the suspected lard one of these chemists obtained three per cent. of stearine, another five per cent., and a third eighteen per cent.

The case stood, therefore, as follows: five chemists, only one of whom enjoyed even a local reputation, claimed the ability to detect tallow in lard by chemical tests, and asserted that they had by these tests found that the samples in dispute were adulterated with tallow. Nine other chemists, including five of national reputation, asserted the impossibility of detecting tallow adulterations by the methods used by the prosecution; and they accordingly maintained that the analyses based upon these methods were utterly unreliable, and that the results obtained did not, therefore, cast the least suspicion upon the purity of the lard in question. The directors of the Board of Trade, sitting as a jury, devised a plan for

satisfying themselves upon the disputed point. They prepared five samples of lard, pure and adulterated, and submitted a portion of each sample to each of five chemists for examination. These gentlemen were, first, the most prominent chemist on the side of the prosecution, Mr. Delafontaine, upon whose testimony indeed the charge of adulteration was chiefly based, and who had asserted that the suspected lard contained at least twenty or thirty per cent. of tallow; second, the private chemist employed by the defence in their packing house, Dr. Rose, who had denied the possibility of detecting tallow adulteration by chemical means. The three other gentlemen selected were outsiders who had not been engaged upon the trial, and who were without exception inexperienced in the examination of fats. It seems somewhat strange that the board employed these inexperienced gentlemen rather than three of the numerous experts who had been engaged for months upon the subject in dispute. The results might have been more satisfactory had the latter plan been pursued. Yet it was abundantly demonstrated that no one of these five gentlemen was able to do what the chemists for the prosecution had claimed for themselves. Every one of them either failed to detect adulterations where they actually existed or found them where they did not exist. The analysis of Mr. Delafontaine had, of course, especial interest, since he had by his evidence during the trial endeavored to impeach the commercial honor, and to ruin the business of the defendants. By this analysis, however, he demonstrated most clearly the utter unreliability of his statements in evidence. The first two of the five specimens submitted to him were absolutely pure lard; yet in these he detected both tallow and cotton-seed oil. In fact, in only one of the five were his results even approximately correct. The results of the analyses made by the other gentlemen supported perfectly the position taken by the chemists for the defence, namely, that chemistry is impotent to detect the presence of tallow when mixed with lard.

The use of the microscope for the detection of the adulteration of lard is a point entirely new in science, upon which there is no literature to consult. The unanimous result obtained by all the microscopists engaged upon the work is that there is at present no means for detecting an adulteration of lard with cotton-seed oil by means of the microscope. This is a matter of minor importance, since chemistry has now, thanks to the skill and industry of Prof. S. B. Sharpley, of Boston, a test whereby cotton-seed oil can be detected in the presence of lard even when it constitutes but five per cent. of the mixture. This test consists in the difference in the shades of color produced upon the addition of sulphuric acid to the fat. This color test is quite independent of impurities in the oil, since it gives perfectly characteristic results with the bleached oil or even with cotton-seed stearine. Yet a new and brilliant field was opened for and by the microscope in the detection of tallow in lard. This discovery is the more valuable since chemistry is at the present time—as has been demonstrated in this investigation—quite unable to detect such adulteration. The possibility of distinguishing tallow from lard rests upon the fact that crystals characteristic of these substances respectively can be obtained by dissolving the fats in certain liquids and permitting them to crystallize. This fact, first made public during this trial, was discovered some two years ago by Dr. P. B. Rose, of Chicago. Dr. Rose's method consisted in dissolving the tallow and the lard in turpentine, and permitting the solutions to stand until crystals were formed; these crystals were then examined under the microscope in turpentine. Several of the gentlemen who were engaged for the defence repeated Dr. Rose's experiments, with varying results. All but one of them adopted his method or some modification of it. Dr. W. T. Belfield devised a somewhat different plan, which he demonstrated to be superior to that

employed by Dr. Rose; its superiority consisted mainly in the fact that the characteristic crystals of both lard and tallow were clearly brought out even in small adulterations. This method has been adopted by two of the gentlemen who had previously employed that of Dr. Rose.

The method as devised by Dr. Belfield is essentially as follows: ten grains of the fat are dissolved in two drachms of Squibb's ether in a test-tube, which is allowed to stand uncorked for twenty-four hours (this time is usually sufficient to permit crystals to form at the bottom and sides of the tube in warm weather). If extreme accuracy is required certain details must be observed which it is unnecessary to describe here.

Treated in this way it will be found that the crystals deposited from the solution of lard are long, thin rhomboidal plates with bevelled ends (Fig. 1); these vary ex-

FIG. 1.

remely in size according to the rapidity with which the evaporation has taken place. They are often arranged in rosettes, though not necessarily so.

The crystals from the solution of tallow, on the other hand, when treated in this way never show the rhomboidal plates characteristic of lard; these tallow crystals are found in masses resembling somewhat the letter "S" in shape, though the curves are not so pronounced (Fig. 2). These masses are found to consist of numerous small crystals, each of which is shaped somewhat like an italic "F." The size, shape, and arrangement of these small crystals vary under different circumstances; yet if the method introduced by Dr. Belfield be accurately followed, these crystals of tallow are always distinguishable from the rhomboidal plates of the lard. After this fact had been definitely ascertained and established, it remained to be seen whether these crystals, which are so characteristic of the lard and tallow respectively in the pure state, were to be found when the two are mixed as in adulterations. In order to decide this point, mixtures of the two fats in known proportions were examined. Each of the gentlemen engaged for the defence found that these crystals were present in the admixtures in which the tallow formed a considerable percentage. They differed somewhat in their experience as to the delicacy of this test. This difference in their ability to recognize minute adulterations seemed to depend upon the time and experience which they had gained as well as upon the method used; thus one of the gentlemen, Prof. Stuart, limited his ability to the detection of a twenty-five per cent. admixture of tallow. Dr. Belfield, on the other hand, demonstrated that by his method even a five per cent. adulteration could be detected in the following test: a series of

nine samples of lard was prepared by one of the chemists and submitted to Dr. Belfield for examination; these samples were lettered A, B, C, etc., and further than that the examiner had absolutely no knowledge as to their composition. As the result of careful microscopical examination, Dr. Belfield reported in writing that five of the nine samples contained tallow, while in the remaining four he was unable to detect any signs of this substance—that is, he could find none of the characteristic curved crys-

FIG. 2.

tals. A comparison of his report with the memorandum made by the gentleman who had prepared the samples showed that Dr. Belfield's results were accurate in every particular, and that he had detected the tallow in one of the samples where it formed only *five per cent.* of the weight, the remainder being pure lard. Three of the four samples in which no tallow was detected proved to be three of the samples whose purity was under dispute.

Micro-photographs were prepared by Dr. Belfield exhibiting to the board of directors the characteristic crystals of lard and tallow respectively, both in the pure state and when mixed in the form of adulterations. These have since been reproduced by the artotype process, and have been widely circulated in the official report of the Board of Trade as well as in the printed argument submitted to the board by the defendants.

Although the board of directors were perhaps not wholly impartial jurors, since most of them were pecuniarily interested in the result of the trial, and one member was even a subordinate in the business employ of the accuser, yet their verdict is interesting as well as valuable. They declare that the charges "have not been sustained," and are therefore dismissed. They further say: "The board of directors would embrace this occasion to express their gratification that as the result of this investigation this question of ascertaining the truth as to adulterations in lard by scientific examination, which has hitherto, to say the least, been one of extreme difficulty, seems now to give promise of a satisfactory solution. The board feels great encouragement to believe that even small adulterations with cotton-seed oil can be detected by some of the methods detailed in the evidence submitted in this case by scientific gentlemen, and that the microscope in the hands of an experienced operator can be successfully employed in detecting adulteration by beef product where it exists to the extent of ten, and probably even a much less percentage."

FLOATING KIDNEY.—Professor Senator's conclusions concerning floating kidney, based upon the records of thirty-two cases (*British Medical Journal*, September 29, 1883), agree in almost every particular with those

to be found in Landau's *Wanderniere der Frauen*. Senator terms the affection "ectopia renis." He found one in every 139 sick women to be subject to floating kidney, independently of age or social station. Disappearance of the fat around the capsule of the kidney can hardly be a cause of this condition, for there is little or no such fat in children, among whom floating kidney is very rare, and men are as liable to emaciation as women, yet floating kidney is much less frequent among men than in women. The absence of fat, as Senator most pertinently observes, does not cause floating kidney, but facilitates diagnosis. The causes are more probably to be found in the condition of the generative organs and defects of attire. Repeated pregnancy causing pendulous abdomen is a very probable cause; and uterine displacements are considered by Landau to influence the position of the kidney; the same authority attributes displacement of the kidney to tumors and hydronephrosis, but Senator has never observed these pathological conditions in any of his cases. Tight-lacing is considered as a highly probable cause of floating kidney, as Mr. Clement Lucas observed in a recent paper on surgical diseases of the kidney, and would account for the greater frequency of displacement of the right kidney, which, in a tight-lacing woman, is subject to prolonged pressure by a large solid body, the liver. The greater length of the right renal artery favors displacement of the right kidney. To make diagnosis as certain as possible, the patient should first be placed on her back; the abdominal walls must then be thoroughly relaxed by passive elevation of the lower extremities. In examining the right lumbar region, the surgeon or physician should stand on the same side, and place the left hand on the loin posteriorly and the right on the abdomen; in examining the opposite side, these tactics must be reversed. Professor Senator appears to prefer this method to Landau's, for if the medical attendant stand on the opposite side of the patient, with the position of the hands reversed, Senator believes that the displaced organ is more likely to be pushed aside, and thus elude detection.

HOT-WATER ENEMATA IN DELIVERY.—Dr. D. S. Beckingsale writes, in the *British Medical Journal*, that "The value of hot-water enemata as a means of hastening delivery, apart from its use in the removal of fecal accumulation, in such cases of tedious labor in which either ergot or the forceps are admissible, has been hitherto unaccountably ignored in practice, as far as my experience extends. I formerly had warm-water enemata given with the usual object of removing fecal obstruction from the rectum. In most cases an increased rate of dilatation of the os followed. Latterly I have had enemata of hot (not merely warm) water administered, whether there were any appreciable collection of feces or not, and always with the result of an accelerated rate in the progress of labor. The fact of the os dilating under the influence of the enema, whether there was an appreciable quantity of feces or not in the rectum, proves that their presence does not prevent dilatation by causing spasm; at least, not in the majority of cases. It follows that the hot enema must act as a direct and powerful stimulant to the uterine muscle, and I feel convinced, I may add as a result of close observation, also to the voluntary muscles engaged in the act of parturition. Judging from the sense of relief which follows its administration, it has at the same time a relaxing and soothing effect on these same parts—analogue, in short, to the effect of hot water applied in the familiar form of a fomentation to an inflamed and painful swelling. I believe I am justified in adding that there is less atony of the uterus after delivery, when a hot enema has been given, and consequently less tendency to post-partum hemorrhage. On this account it has not the after-relapsing effect of chloroform on the uterus it otherwise commonly has. I submit that it would be as well to give so simple a means of treatment as hot-water enemata a trial in cases in which either ergot or the forceps would be used, as it possesses obvious advantages over both."

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, November 24, 1883.

THE DISCUSSION ON TYPHOID FEVER AT THE ACADEMY OF MEDICINE.

It is a good thing occasionally to take up some well-worn theme and discuss it in the light of recent experiences. And this is especially true in the matter of typhoid fever, which, after having passed through the able hands of Louis, Murchison, and Liebermeister successively, seems hardly to offer the clinician of the present day much opportunity for adding anything new.

But we are apt to forget that there is always something in one's especial surroundings that modifies the type that we have agreed to accept as our standard under the dominating power of distinguished teachers, and it is therefore well sometimes to stop and consider certain other groups of symptoms than those that are classical. For otherwise the physician might justly inquire of himself, as in this case, whether or not it is the typhoid of Louis, or if the deviations from the acknowledged type are not so striking as to warrant us in devising a new classification for the continued fevers.

Probably, however, in the present instance, there is no modification necessary; indeed, one of our very best authorities affirms that the typhoid of to-day is certainly the typhoid of Louis. And yet we have come to look with uncommon interest lately upon the atypical cases that occasionally find their way into print, and which have been especially noted by Dr. Alonzo Clark, of this city, and Hoffmann, of Germany. But the author of the evening's paper touched the root of the whole discussion when he pointed out that atypical cases characterize every infectious disease, depending, in large measure, upon the date and locality of the epidemic. Indeed, we may go further and reaffirm that no known disease has a greater number of complications. But while the clinical train of symptoms vary so greatly, it is surprising what uniformity exists in the pathological lesions, which involve the follicular structures of the intestines in a manner that is peculiar to the affection, and is probably shared by only one other—the much-discussed and well-abused typho-malarial.

Perhaps it was unfortunate that the paper of the evening embraced so few pathological data, comparatively, for room was thereby left for objecting that the conclusions were mainly based upon clinical records, which naturally carry less weight. But turning to another point, it is not an agreeable matter for us to face the mortality figures of the tables of the hospital cases—a topic that

was justly alluded to by the chairman. A percentage of deaths that from 1877 to 1882 has never fallen lower than 20.1 and has reached 30, may well give force to the inquiry whether the methods of treatment have been all they should have been. An explanation suggests itself in the fact that the field of study was too narrow, and that a more comprehensive arraignment of the city statistics might have improved the quality of the returns. Indeed, it was noted in the discussion that, as the history of the disease in children is different from that in adults, we may well be entitled to the returns from the hospitals or asylums where they are specially cared for. It will be in order, therefore, to hear from some of these institutions that were not enumerated in the printed tables. At any rate, this part of the subject is one of the most pressing interest, and cannot be allowed to pass by without a disagreeable contrast of its results with those of Liebermeister, whose personal experience, it will be remembered, covered over fifteen hundred cases. When this distinguished physician undertook his famous apyretic treatment he had been confronted with a mortality of about twenty-seven per cent., a figure that is not far from the average of the printed table; this percentage of mortality was reduced to sixteen per cent. under incomplete apyretic measures, and to eight per cent. under systematized apyrexia (quinine and application of cold).

On the other hand, we have no need to be alarmed at the somewhat increasing annual mortality from the disease in our midst. We should remember that, on the whole, the ratio of mortality has not kept pace with the increase of our population. And when, in 1881, we found an undue proportion of deaths, it may justly be assumed that we had other causes at work—causes that always will be associated with the large floating population of a metropolis. Foremost among them are the well-known facts that hospital accommodation in New York is excellent and often luxurious, while the cheapness and ease of transportation offer special inducements to the sick scattered in the country districts round about. Certainly, the greatest absolute mortality has been during the years 1863–66, the highest figure, 661, being reached in 1864.

It was a curious fact, noticeable in the discussion, that the speakers approached the etiology of the disease with a respectful reserve, and neither Liebermeister's drinking-water-sewer-gas-privy-vault hypothesis nor the later English milk-contamination theory offered attractions that made any one feel willing to risk breaking a lance in its favor.

ACONITINE POISONING.

THE valuable paper by Dr. Thomas Stevenson ("Guy's Hosp. Rep.," vol. xli., 1882) on "Aconite Poisoning," in the case of Reg. vs. G. H. Lamson, is of double interest both to the general and medico-legal practitioner, as accurately detailing the symptoms which we may expect to find in such cases, and the chemical methods by which aconitine can be best recognized.

The length of time after which the symptoms manifested themselves in this case, thirty minutes, may be partially accounted for by the fact that the poison was administered in a gelatine capsule. The first symptom

complained of was heart-burn. When, however, the alkaloid is taken in powder, the first symptoms are referable to the mouth and throat. A burning sensation in the mouth and throat is usually felt in about half an hour after the poison is taken, and becoming more intense every minute. Within three-quarters of an hour intense pains in the stomach come on, the skin feels drawn, violent convulsions, in which the patient rolls from side to side, rapidly ensue, and dysphagia generally, though not always, appears. In some cases vomiting may be a prominent symptom so early as half an hour after the ingestion of the poison. The character of the vomiting is peculiar. As described by Dr. Stevenson it is a kind of spasm, during which the sufferer turns convulsively on his abdomen, with intense contraction of the abdominal muscles, and the contents of the stomach are jerked out with a loud shout caused by the spasmodic contraction of the diaphragm. Peculiar also are the pupillary phenomena. The pupils are, as a rule, dilated, during which time consciousness is not lost, but in some cases they alternately dilate and contract, the patient becoming unconscious simultaneous with the contraction. The respirations are short, irregular, and superficial, and the skin, while feeling drawn, is covered with a cold, clammy perspiration. The violent muscular spasms may extend to the heart; the pulse fails and death seems imminent. This is succeeded by muscular relaxation which lasts for a few minutes, only to be followed by other convulsions, in which the facial muscles participate; the pulse fails, the patient becomes unconscious, and death usually ensues from asphyxia.

In the special case under consideration death occurred within four hours and five minutes after the ingestion of the capsule—containing probably two grains of Morson's aconitine. This preparation (Morson's) is prepared only from the cultivated *aconitum napellus* and is terribly potent, one-twentieth of a grain having caused death; so small a quantity as one two-thousandth of a grain causes the unmistakable physiological effect upon the tongue, and is invariably fatal to mice. Morson's crystalline aconitine is still more powerful, and the crystalline preparation of Petit, of Paris, is said to be even more powerful than Morson's.

With regard to the pathological changes caused by aconitine, its detection in the fluids and solids of the body and in the vomited matters, and the subsequent proof of its nature by physiological experiment, Dr. Stevenson has added much to our knowledge. The pupils dilated during life, with the exception of intermittent contractions occurring simultaneously with unconsciousness, are dilated post mortem. The membranes of the brain are slightly congested, while the lips are pale and the tongue so pale as to look bleached. There is no fluid in the ventricles of the brain or under the meninges. The heart is flaccid, appears stained with blood-pigment, and its cavities are empty. The other organs of the body, save the lungs, are usually intensely hyperæmic. The extent of the congestion of the intestinal tract seems to depend somewhat upon the duration of the case. Where death occurs quickly—within four or five hours—the congestion is more limited to the stomach and duodenum, with patches of congestion in other portions of the intestine. The stomach usually contains a variable amount

of a dark or greenish fluid similar to that vomited during life. The bladder generally contains a few ounces of urine. As might be expected from the violent convulsions, the membranes of the cord are greatly congested.

It is unnecessary to detail the method by which the alkaloidal extracts were obtained from the viscera, vomited matters, and urine. Those who might have occasion to perform a similar analysis would do well to consult Dr. Stevenson's paper. The amount of alkaloidal extracts recovered was one-half grain. It was now necessary to determine their nature; they were tested by taste, with phospho-molybdic acid for alkaloids, and with iodic acid and starch for morphia. It should be remembered that the analysts were entirely in the dark as to the nature of the poisons. Indeed, they first suggested their nature after their experiments had been begun. Lastly, a portion of the extracts was injected into the cellular tissue of mice. Fortunately, the taste of aconite and its derivatives is so peculiar, and the effect on the tongue and mouth so striking, and, we may add, the physiological effect so marked should the experimenter taste too much, that it cannot be confounded with any other known substance.

The effect of the extracts upon the tongue was similar to that produced by aconitine. The effect on the tongue of the three aconite alkaloids, aconitine, pseudaconitine, and japaconitine, are precisely alike. They differ, however, in that aconitine has a physiological action upon the nerves of sensation, and is uniformly fatal, in very small doses, to animals. Dr. Stevenson describes the effects of a solution containing $\frac{1}{1000}$ th grain to the drop as at first a scarcely perceptible bitterness similar to that of all alkaloids, and transient. In about three minutes after the sensation of bitterness has disappeared an intense burning, somewhat benumbing pain, is felt at the spot to which the drop was applied, and radiating in all directions. Immediately after the commencement of this, moderate salivation comes on, with a peculiar feeling of dryness and faucial constriction. The burning, numbing feeling is felt in the lips, especially on the inner surface of the lower lip. These sensations continue generally for hours, according to the quantity applied, and after passing away leave a painful sensation on that part of the tongue to which the alkaloid was applied. The feeling is very properly described as one of "searedness," as though a hot body had been applied to the part, just stopping short of raising a blister. Extreme caution is necessary in making this "taste experiment," and it should be regarded as dangerous to apply more than $\frac{1}{600}$ th to $\frac{1}{300}$ th of a grain. A larger quantity, by the very pronounced physiological effects on the heart, brings up serious thoughts of a last will and testament.

The phospho-molybdic acid test is, of course, only valuable for ascertaining the presence of an alkaloid. The physiological effect of aconitine ($\frac{1}{4000}$ th to $\frac{1}{3000}$ th grain of Morson's, hypodermatically) upon mice is almost as unmistakable as the "taste-test." Within six to ten minutes violent retching comes on. Sensation is rapidly abolished, the retching still continuing; partial or complete paralysis of the posterior extremity appears about ten to thirteen minutes after the injection. Frothing at the mouth appears about a minute afterward, and in from

one to three minutes thereafter the animal rolls or jerks itself over on one side in a violent convulsion, which ordinarily continues until death takes place, about fifteen or twenty minutes after the injection.

THE CHANCES OF THE YOUNG PRACTITIONER AS AFFECTED BY THE "ADVICE GRATIS" AND SMALL FEE SYSTEMS.

IT is pretty generally conceded that the young practitioner has a long and hard struggle to get into a bread-and-butter practice. The time required is variously estimated at from three to five years, according to locality. During this period he must be ready for anything, night or day, and accept any fee, however small or disproportionate to the services rendered. If there are no dispensaries in his neighborhood, or college clinics, he has the ordinary show for a young, hard-working doctor.

Away from so-called educational centres he may get the usual reward by learning to labor and to wait. But how few such places are! The aspiring youngster generally looks toward a large city as a legitimate field for his ambition. Generally this is the worst place he can select. If he wishes to begin at the bottom, the college clinics, dispensaries, and free hospitals stand in his way. Such as should be his patrons know it, and are not willing to pay even small fees when they can get services for nothing. And such services! Real professors, men who, of course, must know more than the ordinary rank and file, are ever ready and willing to gather the sick ones from the highways and by-ways that they may not want for skilled advice and treatment. Clinical material is needed and it must be had. It is a business in itself, and has to be cultivated after the usual fashion. Fences are placarded showing where free advice may be obtained, where obstetric services can be secured by skilled men, where operations can be performed without money and without price, where every diseased organ can be properly cared for by distinguished specialists. Only the really poor are invited, but the more of the others who do come the more interesting and profitable is the clinic. Teachers seldom object to an unique case, rich or poor. It is the case, nothing more or less. Who can blame an honest, struggling mechanic with a rapidly growing family for stretching his conscience to get for nothing what would otherwise involve pecuniary outlay? The temptation to contribute to the advancement of science is, of course, too strong for him to resist. If "no questions are asked" he is under no obligations to answer. He gets first-class advice and treatment. What better can he desire? The young doctor around the corner is the only one who suffers. It is the survival of the fittest, after all. Which is which? The man who must have clinical material, or the man who must have bread-and-butter? But then the professor is not expected to be his brother's keeper, and the mechanic can lay up something more for a rainy day.

We confess to some pity for the young man who wishes to work and is left with nothing to do. He has some right to a decent show. It is the old story, of course, about the clinics taking away his patients. But it is getting truer every day. In old times, when there was fishing with hook and line, there was room for all who wished to take their chances. Now stock companies drive their

stakes in the channel and stretch their drift-nets almost from shore to shore. Is it any wonder that those who are compelled to troll behind the net have, figuratively speaking, the usual luck of hopeful but foolish fishermen? How many there are of these! Men whose baits are washed away by long waiting, who seldom experience the delusive excitement of a promising nibble.

But we are told that the poor should not be allowed to suffer. They never would, even if there were no dispensaries or clinics. Each physician would gladly take his share, and could thus discriminatively dispense his charity. It is done quietly and effectively in all localities where dispensaries and free clinics do not abound. In fact, the deserving poor are liable to be better treated in such places than when under dispensary patronage. There is not a young practitioner in any large city who would not be willing to give his services gratuitously to half of such as called upon him and deserved the same. He could at least be satisfied that he was trying to do his best and to get what money he could. As it is, the small fee patients are thoroughly demoralized. Poverty is only a relative term. Some sneaking frauds, no matter how rich they are, can always make themselves believe they are too poor to pay any fee when not compelled to do so. There is no question of conscience with them when it comes to cheating a poor doctor. What account have our clinical teachers to render on the same score who do not seem to know or to care how many of the patients they treat for nothing should pay a fee to some young doctor! The question will by-and-by be between the college and dispensary clinics and the rank and file of the profession. The latter will be forced to seek their own protection by new methods. The clinics are their enemies and they must be fought in some way or other. Practitioners, for mere self-protection, may be forced to set apart spare hours in their offices for the free treatment of the poor, and thus leave the dispensaries out in the cold. What is right for any body of men to do in advertising to give advice gratis to the poor is right for a single individual. This would certainly be one way out of the difficulty.

Again, young men are content with small fees; why not throw them in their way? The distinguished professor can afford to do this and narrow his work to a more profitable sphere of usefulness and emolument.

A MAN TO BE REMEMBERED.

THERE are not many who have the opportunity and ability to create an enduring monument of their passage through life. Dr. Jonathan Letterman, however, was one of these, and his memory has been faithfully and tastefully commemorated in a memoir recently written by Dr. Bennett A. Clements, U.S.A.

Dr. Letterman was born in 1824, and graduated from Jefferson Medical College in 1849. In the same year he entered the medical service of the army. He served in Florida during the Seminole War, and then was for several years on the frontier. At the breaking out of the war he accompanied troops from California to the East.

It was in June, 1862, that Dr. Letterman received his appointment as Medical Director of the Army of the

Potomac, in which position he accomplished a work which makes his name historic.

At that time the organization of the medical corps, especially as regards the work during active service, was very imperfect. The arrangements for removing the wounded at once from the field, and for furnishing immediate surgical and medical relief, were of the most unsatisfactory kind. Furthermore, there were no good precedents or models to follow in the medical organizations of European armies. At the time of Dr. Letterman's appointment, also, the army was exhausted by its conflicts and the malarious atmosphere of the Peninsula, and needed the utmost skill to secure its reorganization. Dr. Letterman was selected as the man best qualified to meet these emergencies, and was given large discretionary powers by Surgeon-General Hammond.

The result of his labors was the organization of an Ambulance Corps and of the Field Hospital System. By the practical application of these schemes the medical service of the army in the field was made incredibly more effective. In a short time its merits were recognized by the whole army, and it served as a model in all the other departments. It is not easy to compute the number of lives saved and the amount of suffering prevented by the system thus introduced. Dr. McNulty, referring to its working, writes:

"It is with extreme satisfaction that I can assure you that it enabled me to remove the wounded from the field, shelter, feed them, and dress their wounds within six hours after the battle ended, and to have every capital operation performed within twenty-four hours after the injury was received."

"Dr. Letterman's claims to the grateful remembrance of his profession and of his countrymen," writes Dr. Clements, "rest mainly upon the great services he rendered to his Government in the Army of the Potomac. To him is justly due the praise of originating a system of medical administration which alleviated the sufferings and preserved the lives of thousands of his countrymen, added to the vigor and effective fighting strength of the principal army of the Republic, and materially aided in perfecting and maintaining its discipline; and which has had no equal in the armies of modern times for simplicity and effectiveness."

Dr. Letterman left the army in 1864 and spent the remainder of his life in California, where he died in 1872. He was a man of simple and straightforward character, direct and plain in speech, genial and modest in disposition.

It is a pleasure and a duty to recall to our readers the record of a life so honorable, a work so noble and beneficent, as was that of the Medical Director of the Army of the Potomac.

THE ALLEGHENY COUNTY MEDICAL SOCIETY FROM AN INSIDE VIEW.

WE are glad to have received from Dr. W. H. Daly, of Pittsburgh, Pa., a letter concerning the condition of the Allegheny County Medical Society, referred to editorially some weeks ago. Dr. Daly was recording secretary of the society for ten consecutive years, and later its president; he denies very emphatically the exist-

ence of any such state of affairs as was pictured at that time. His letter is too long to publish in full, but we take pleasure in giving the essential features of it. Dr. Daly explicitly denies the statement made by our correspondent that "one of the popular members" of the society had advertised for a year in the daily papers, and had lately announced that he gave special attention to diseases of the eye, ear, etc. He also denies that a member who had been abroad requested, upon his return, the press to announce the fact with suitable comments. He admits that a physician who had been abroad announced his resumption of practice by an advertisement "of two lines." This is thought to be perfectly proper, however, as the gentleman in question had been away for nearly two years, and it had been rumored that he would remain abroad or would not return to Pittsburgh. As regards the statement that some of the Pittsburgh physicians had called a certain private hospital the "Pittsburgh Abbatoir," Dr. Daly shows that the imputation is discreditable and unjust. In six months there were performed 19 operations with 2 deaths. The charge that certain physicians keep selected formulæ at the druggists is explained by saying that these formulæ are simply the same that have been used by many of the doctors in the public dispensary. They have been printed and widely distributed among doctors and druggists. Dr. Daly challenges proof that any member prescribes such things as "my mixture" or "my application." Dr. Daly does not believe that any physician attends families at ten dollars a year, and asks for proofs of such accusation. To the charge that there are in the County Society men without diplomas, and men with diplomas from eclectic medical colleges, it is said that the constitution of the society admits to membership any regular practitioner of at least fifteen years' standing, and of good moral and professional reputation. While there is a graduate of an eclectic college and a physician without a diploma in the society, they are both good and constitutional members. As regards the signing lunacy certificates with homœopaths, the immorality of this procedure is questioned. The existence of quacks in the society is denied, and it is also asserted that Dr. Jas. King did not point out any when he was alive, and was not, in fact, a very active member of the society. As regards the charge that many of the best practitioners are not members of the society, and that others contemplate resigning, Dr. Daly gives facts showing the prosperity of the society. The charge that a medical college is soon to be started is freely admitted, and we are promised an excellent one. The profession in Pittsburgh is said to be doing very well, most, if not all, of the doctors earning a comfortable living. In conclusion our correspondent says: "The Allegheny County Medical Society comprises a large, if not the largest, portion of the best medical talent in the city. In its ranks are men who are the peers of the best, purest, and most respected citizens in the land. On its rolls are borne the names of physicians who are the trusted medical advisers of men and their families whose intelligence could not be imposed upon by quacks of any profession. Its representatives have been honored associates in the highest and most learned medical bodies of the nation, and from its roll have been selected men who have creditably served in the councils and in the scientific deliberations of the

various foreign medical congresses. In the list of American delegates to the International Medical Congress which met in London last year, and whose scientific labors were a wonder of ability and comprehensiveness, the names of members of the Allegheny County Medical Society are there, side by side with others, alike respected and worthy of the esteem of their countrymen."

A UNIVERSAL MEDICAL REGISTER.

THE erection of the new École de Médecine in Paris, to which we have already referred, includes the erection of a library building. The future library is to be made to include as many as possible of the medical books and pamphlets that have been published. The total number of books which would have to be collected for a complete library is about 122,000, while the number of pamphlets is 250,000. It is evident that no such collection could be made, or indeed is needed.

Another project, more novel and less ambitious, though difficult enough, is to keep a register of all the legally authorized medical practitioners in the civilized world—or at least in America and Europe. The number is supposed to be about as follows: United States, 65,000; France, 26,000; Germany and Austria, 32,000; Great Britain and its Colonies, 35,000; Italy, 10,000; Spain, 5,000.

Such a register, if carefully kept, would certainly be of considerable value, especially to advertisers.

THE LIBERTY OF SPECIALISTS TO ANNOUNCE THEIR SPECIALTY.

THE *Louisville Medical News* calls attention to a fact which we believe has been forgotten by many. It is that the American Medical Association, which has been proudly designated as the guardian of the ethics of the profession, has given a specific consent to allow specialists to designate their specialty upon their professional cards.

In 1874 the Judicial Council, in accordance with a request made by the Association the previous year, made a report upon ethics in which the following quotation occurs:

"The Code of Ethics very properly makes no mention of specialties or specialists, but presents plainly the rules necessary for the maintenance of professional character as applicable to all. But we are asked how, then, can those who wish to pursue a special practice make known their position to their brethren and the public? We answer that the title of Doctor of Medicine covers the whole field of practice, and whoever is entitled to that appellation has the right to occupy the *whole* or any part of the field, as he pleases. The acceptance of this honorable title is presumptive evidence to the community that the man accepting it is ready to attend practically to any and all duties which it implies. *As all special practice is simply a self-imposed limitation of the duties implied in the general title of doctor, it should be indicated, not by special or qualifying titles, such as oculist, gynecologist, etc., nor by any positive setting forth of special qualifications, but by a simple, honest notice appended to the ordinary card of the general practitioner, saying, 'Practice limited to diseases of the eye and ear,' or 'to dis-*

eases peculiar to women,' or 'to midwifery exclusively,' as the case may be. Such a simple notice of limitation, if truthfully made, would involve no other principle than the notice of the general practitioner that he limits his attention to professional business within certain hours of the day. Neither could it be regarded as a claim to special or superior qualifications. To give the specialist any privileges beyond this would be to invest him with a special advantage inconsistent with the equality of rights and duties pertaining to the profession."

The report was adopted and its sentiments have been recently endorsed, we are informed, by the distinguished editor of the *Journal of the American Medical Association*.

The sentiments and views thus expressed certainly appear to be fair and sensible. But it will be conceded that the permission thus granted is one liable to very dangerous abuse. The question when a person can draw the line in the matter of the wording upon his cards, and to what extent he can distribute these cards, would certainly involve some very delicate distinctions. It is creditable to the wisdom and good ethical sense of the profession that so far the permission thus to designate a specialty has not been to any extent taken advantage of. We trust that physicians will continue to show that they are capable of taking loftier views of professional dignity than the Judicial Council of 1874.

THE DIAGNOSIS OF GASTRIC DISEASES.

A NUMBER of new methods have been devised of late for the more exact examination of pathological disturbances of the stomach. The use of substances which are rapidly taken into the blood and reappear in the saliva and other secretions, the washing out of the stomach and examination of the fluid thus obtained, the gastroscope, palpation, percussion, and surface thermometry all combine to make the examination of gastric diseases much more definite than it used to be. Quite recently M. Romelaere has added to the above methods of research another one, viz.: the examination of the urine. His views, first expressed some months ago, have been confirmed by further experience, and he now announces (*Journal de Médecine de Bruxelles*) the following conclusions: A cancerous ulceration of the stomach is attended with diminution in the amount of urea excreted per diem and also of the urinary chlorides. Simple gastric ulcer is associated with normal azoturia (if that expression be allowed), or even hyper-azoturia, and the chlorides are of normal amount or in excess. Spreading gastric ulcer is accompanied by normal or hyper-azoturia, but with decrease in the chlorides of the urine.

This help, which the above formula, if correct, would give in cases where early diagnosis of cancerous disease is desired, will be very apparent.

KAIRIN AND ALBUMINURIA AFTER HEMORRHAGE FROM THE BOWELS IN TYPHOID FEVER.—We have received from Dr. T. A. McBride an article on these topics which would have been well placed had it appeared in the same number containing the discussion on typhoid fever, but it came too late for this week.

News of the Week.

THE MEDICAL FATHERS OF NEW YORK.—Bearing on the question of longevity of medical men who spend active lives in their profession, we are enabled to instance other striking examples. Our friend Dr. Alfred C. Post has very significantly said that a man's age is not counted by years; that some are as young at seventy as others are at forty, and we are happy to say that his present condition proves it. The same principle applies in many particulars to Drs. Alonzo Clark and James Anderson, each eighty years of age, and the active veteran Dr. Jared Linsly, aged seventy-nine. The latter gentleman has been in full practice in this city for over fifty years, and knows more about old New York than any practitioner living. When he commenced practice the greater part of the city was a wild, open country. Many of his present patients are great-grandchildren of his earlier patrons.

THE FIFTEENTH ANNIVERSARY OF THE PRESBYTERIAN HOSPITAL, New York, was held at the Collegiate Dutch Church, Forty-eighth Street and Fifth Avenue, on Sunday evening at eight o'clock, before a large audience. Addresses were made by Rev. John Hall, D.D., of this city; Rev. Dr. Arthur Mitchell, of Cleveland, O.; and Dr. George F. Shrady, one of the visiting surgeons of the hospital. Mr. George W. Lane, president of the Board of Managers, presided.

Dr. Hall referred to the loss which the hospital had sustained during the year in the death of ex-Governor Edwin D. Morgan, William E. Dodge, and Robert L. Stuart, all members of the Board of Managers and warm friends of the enterprise from its inception. He eulogized Mr. Stuart, saying that few men he had known "had paid as little regard to popularity." He referred to the gifts of an ambulance and an elevator which the hospital has received during the past year, and also to the kindly efforts of Christian women to make the wards attractive and the inmates comfortable. Criticisms of the name of the institution as indicative of narrowness were, he said, disposed of by the annual report, which showed that of every 100 patients 50 were Protestants of various denominations and the other 50 Roman Catholics.

Dr. Shrady, after alluding to the general increase of usefulness of the hospital, presented some of the more striking incidents occurring during a day's visit to the wards.

Dr. Mitchell, of Cleveland, O., concluded with an address on the magnitude of the work done at the hospital and its growth, and gave an account of the Presbyterian hospitals in Asia. A benediction by the Rev. Dr. Talbot Chambers closed the services.

The report for the last year shows that 1,223 patients have been admitted during the year, and, including those in the hospital at last report, 1,297 have been treated. The rapid increase of benevolent work is most clearly evidenced by the fact that one-half of all the patients treated since the hospital was opened have been cared for in the past three years. Forty-three per cent. of all admissions during the year have been brought by the ambulance in response to calls from the Twenty-third and Twenty-eighth police precincts. Nearly all were acci-

dent cases, and most were working-men, injured while engaged upon the many new buildings in the district east of Central Park. All these patients were in the wards, receiving the best care, within a very few minutes after the call had reached the hospital.

Messrs. McKay, Trowbridge, and Brewster have donated a new ambulance to the hospital, and Mr. Heber R. Bishop has presented an elegant passenger elevator.

The erection of new pavilions is contemplated, to meet the urgent demand for increased accommodation.

DR. S. S. CARTWRIGHT, OF ROXBURY, N. Y., has been elected member of the New York State Assembly for the county of Delaware. We congratulate the profession of the State on securing such a worthy representative.

THE BRAIN OF THE NOVELIST TOURGENIEF is said to have weighed 2,012 grammes, or about 63 ounces. This, if correct, ranks the brain among the half-dozen heaviest that have been reported.

THE FIRST CASE OF SMALL-POX IN THIS CITY since last June was discovered by the sanitary authorities November 17th, in a tenement-house on West Fifty-ninth Street, which is inhabited by ten families. The patient, who arrived from Ireland two weeks ago, was removed to the Riverside Hospital.

MARYLAND STATE SANITARY CONVENTION.—A sanitary convention will be held in Baltimore, Md., November 27th and 28th.

THE BIOLOGICAL LABORATORY of the Johns Hopkins University has been completed.

THE INDIANA STATE BOARD OF HEALTH has distributed circulars and will undertake the task of making a report upon the sanitary condition of all the school-houses in the State. The *Indiana Medical Journal* says: "If the Board succeeds in improving the deplorable hygienic conditions in or around almost every school-house in the State it will have covered up a multitude of sins in the past, and in a measure regained the confidence of the profession and citizens of the State."

EDWARD BURKE THE CHAMPION CORPSE HANDLER.—In THE RECORD for last week we published an item of news, entitled "The End of a Curious Career." Under this heading was given a brief sketch of a "well-known figure in connection with the Morgue, in this city." It was said that "he died last week;" that he "had probably handled more corpses than any man in the world;" and that "his pet and particular abhorrence was a newspaper reporter." The story has some interesting features. In the first place, Burke has not yet furnished "the end of a curious career." He still lives, and can be seen in Ward 19, Bellevue Hospital. Old Charon rowed his boat along close to the shore, and invited Burke to ride across the river, but being "a quiet man and having but little to say to strangers" he declined the invitation. He has not yet entered the crib, and hopes to live to meet "that newspaper reporter" who shuffled him off. It was also said that "Burke was not a man of tender susceptibilities." Admitting this to be true, we are prepared to understand that said reporter, under favorable circumstances, might be added to the "50,000" [yes, many more than that] corpses which Burke has handled. We are pleased to be able to chronicle that

the well-known figure of Burke has not permanently disappeared from the Morgue, and hope he may again be able to assist at "thousands of post-mortem examinations."

MEDICAL DEPARTMENT OF DARTMOUTH COLLEGE.—At the last commencement, November 13th, there were forty graduates. Addresses were made by President S. C. Bartlett and A. P. Richardson, M.D.

UNITED STATES MEDICAL COLLEGE AND ITS LEGAL STATUS.—In answer to a question from a correspondent regarding the legal status of the United States Medical College, we append the following from Dr. D. Webster, President of the Medical Society of the County of New York: "The United States Medical College of New York" is not and never was a legally chartered medical college, and none of its graduates are legally qualified practitioners of medicine. The institution has taken its case up to the Court of Appeals, however, as a last resort, and until the case has been there finally disposed of I think we will do well to refrain from interfering with the 'doctors' who graduated from that college in good faith. The New York County Medical Society has as yet brought no action against any of them."

THE NUMERICAL STATUS OF THE CODE QUESTION.—We have received from "The Central Organization of the New York State Medical Association to Uphold the National Code of Ethics" a pamphlet showing the vote or non-vote of the members of the medical profession in this State on the Code of Ethics. The figures given are: National Code, 2,424; New Code, 943; no code, 210; unclassified, 31; uncommitted, 1,611; total, 5,219. In New York County, out of about 1,800 names 764 are placed among the National Code party. We recognize here, however, many names of those who voted for Dr. Vander Poel at the County Society. Despite all efforts, a majority for the National Code has not been secured. Many of those who have given their names would, we believe, prefer to be among the uncommitted. We ask, now, will a minority of the profession continue to try and force upon the majority the enactment of a disciplinary by-law which accomplished nothing but to lower the physician in public esteem?

SUIT AGAINST THE SECRETARY OF THE ILLINOIS STATE BOARD OF HEALTH.—A Dr. Frank B. Smith, of Detroit, Mich., has begun a suit for fifty thousand dollars in the United States District Court against Dr. John H. Rauch, Secretary of the Illinois Board of Health, whose name, he alleges, was signed to a circular revoking his (Dr. Smith's) license for unprofessional and dishonorable conduct. This conduct, the plaintiff adds, consisted in his advertising his presence when he was a delegate to a health convention at Peoria.

THE SATURDAY AND SUNDAY HOSPITAL COLLECTIONS.—At a meeting of the Saturday and Sunday Hospital Association, November 20th, a report of the Executive Committee was read. This showed that 293 churches and synagogues had promised to take a collection on next Hospital Sunday. The various hospitals represented in the Saturday and Sunday Association have submitted their annual statements as a basis to guide the action of

the distributing committee in allotting the undesignated portion of the forthcoming collection. These statements possess a general interest, moreover, and when compared with the exhibit of the first published statement of 1881, give evidence of a vigorous growth in hospital work in this city. It is thus seen—1, that during the past three years \$201,651.44 were expended on the enlargement of accommodations among the hospitals thus associated; 2, that there has been an increase in the income from the invested funds of \$9,780.12; 3, that there has been an increase of income from paying patients aggregating \$43,036.72; 4, that the increase of income from contributions toward current expenses other than derived from the Saturday and Sunday collection is \$22,774.84; 5, that the total number of patients has increased from 8,688 to 10,023; 6, that the total number of free patients has increased from 6,698 to 7,188, these last having been maintained at a cost of \$307,790.81. This exhibit is claimed to be a sufficient answer to the statement to which publicity has recently been given in some quarters (said to be based on London experiences), that the method of general collection fostered by the Saturday and Sunday movement is inimical to the real interests of hospitals, in that it has a tendency to divert from them special gifts and bequests, because of the impression falsely conveyed that the one general collection is ample for the maintenance of all the hospitals benefited by it. It must be admitted that the London hospitals have been in great financial straits of late years.

TROUBLE AMONG PHILADELPHIA MEDICAL STUDENTS.—The daily papers give accounts of much unhappiness between the students of Jefferson Medical College, Philadelphia. It appears that the senior students thought that they were crowded out by the juniors from the best seats at the clinical lectures. They therefore called a meeting, organized, and addressed a petition to the Faculty setting forth their grievances. The juniors then called a meeting also, and circulated a counter-petition. During this meeting some of the senior students came in, and after a free interchange of paper wads the gas was extinguished. A general mêlée in the dark followed, with the result of producing some interesting cases of minor surgery. Next morning, when the two classes assembled, the row began again, and there seems to have been something in the nature of a free bruising matinée.

We regret to learn of such incidents as the above, and venture to express the wonder that some of the more pacific sections of the National Code of Ethics were not read to these violators of order.

THE STATE BOARD OF HEALTH held a meeting at Albany on November 21st. Various reports showing the progress of sanitary work were made.

FIRST AID FOR THE INJURED.—The Society for Instruction in First Aid to the Injured held its annual meeting in its rooms, in East Fourteenth Street, November 21st, and the old board of officers was elected, with the Hon. John Jay as President and Dr. Henry B. Sands as Medical Director. Plans were discussed for further disseminating among all classes practical information on preliminary treatment of the injured, and for establishing branch societies in smaller towns.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, November 15, 1883.

FORDYCE BARKER, M.D., LL.D., PRESIDENT, IN THE CHAIR.

THE Statistical Secretary, DR. F. V. WHITE, announced the death of J. Marion Sims, M.D.

THE PRESIDENT spoke as follows: By the death of Dr. Marion Sims the Academy of Medicine, the profession of this city, and, I may well add, the profession of this country, has lost its most original and most brilliant genius in the department of surgical gynecology. This will be conceded by all. Had circumstances forced him to equal activity in other branches of surgery, his promptness and fertility in practical suggestion, his intuitive power of conception of new means to secure any desired result, his endowment of invention and wonderful mechanical adroitness, would undoubtedly have secured for him equal eminence in all of its departments. No one can be compared with him in his own sphere, in which he achieved such great distinction, except the late Sir James Y. Simpson. An intimate acquaintance with both for many years will perhaps justify me in saying that there were many points as to their intellectual and moral qualities which were strikingly characteristic of both. These resemblances were much more numerous than the points of contrast. In the future, the greatest fame of one will rest on his courage, and I may even say audacity, in successfully introducing anæsthetics to relieve the agonies of parturition; of the other, by his genius in devising new methods of physical exploration and new surgical procedures which effect cures of lesions which before could neither be correctly diagnosed nor successfully treated.

In thus alluding to the greatest achievements of the two, I should also add that both were incessant, zealous workers who for many years were constantly making positive contributions to our science and our art, many of which would alone establish their claim to be regarded as great men in our profession, the former adding more to our scientific literature and the latter more to the advancement of our art. Neither of them were reluctant to have their good work appreciated.

To-morrow morning I doubt not every Fellow whose engagements will permit will be present at the funeral services of our late eminent associate.

The Chair, in accordance with our By-Laws, will designate Dr. Thomas Addis Emmet to read a memoir at the first meeting of the Academy in January.

DR. FRANCIS DELAFIELD then read a paper on

TYPHOID FEVER IN NEW YORK (see p. 531).

THE PRESIDENT regarded the paper as one of the most analytical contributions to our positive knowledge of this disease which had been made since the writings of Murchison. He also suggested the following points, which he thought worthy of discussion. First, with regard to the percentage of mortality. It should be remembered that the paper was based upon hospital statistics alone, and doubtless many of the patients had not been placed in a hospital until they had reached an advanced stage of the disease. For twelve years, in the fever hospital in London, Murchison states that the mortality was fifteen per cent. In private practice Dr. Barker thought that fifteen per cent. was a rather high rate of mortality.

Another point which struck him with some surprise was the small proportion of cases in which there were prodromic symptoms. Perhaps this also was due to the fact that the patients were hospital patients, and yet it might be the fact that prodromic symptoms are absent in a larger proportion of cases than we have been accustomed to suppose.

Another point, and one which had attracted his attention for several years, was that the temperature did not seem to be a measure of the severity or the mortality of the disease. In some of the most dangerous cases the temperature does not rise above 101° to 103° F., and in others in which the patients recover the temperature rises as high as 105° F., or even considerably higher, but they do not have other symptoms of a severity corresponding with the temperature. Again, the large proportion of cases in which diarrhœa occurred as a symptom in the first week of the disease was noticeable; much more frequently than he had observed it. He also observed that twenty-five per cent. of the deaths were apparently due to hemorrhage from the bowels, and Dr. Barker thought this would accord with the experience of almost all.

DR. ALFRED L. LOOMIS said he was interested to be present, first, because Dr. Delafield was to read the paper, and, second, because he wished to know how the author of the paper would define typhoid fever. A very carefully prepared analysis of the cases of this disease, as it has appeared in our hospitals during the last five years, had been given, embracing the symptoms which mark the development and the course, together with the morbid anatomy of ordinary continued fever; but there did not appear in the record a history of the characteristic symptoms of typhoid fever as we have been led to believe it exists in other countries. For example, if we take the description of the disease given by Liebermeister, it does not accord at all, in its main features, with the record given by Dr. Delafield, and the question comes back to us, What is typhoid fever? Is it a specific form of fever, due to a specific cause, characterized by symptoms always present, and attended by pathological lesions always the same? Liebermeister says it is a specific fever; that it has a specific and characteristic history; that it is due to a specific poison; and that it requires a specific treatment. The characteristic symptoms described in the writings of European observers are, first, a typical range of temperature, a gradual rise during the first week, an even line during the second week, a remittent range during the third week, and an intermittent temperature during the fourth week of the disease. Such a range of temperature did not appear in the cases reported by Dr. Delafield, nor had it been present in any of the cases of typhoid fever which he [Dr. L.] had seen in New York, if it may be called typhoid fever.

The second characteristic symptom is the eruption, appearing between the sixth and tenth day of the fever, each spot remaining visible for three days and then disappearing, one crop to be followed by another until the end of the eruptive period, which may continue for two weeks, or only a single crop of spots may appear. According to the record given by Dr. Delafield, the eruption was present in scarcely one-half of the cases. According to his own observations in hospital and private practice, the eruption has been the exception, and when present it appeared late and was not the characteristic rose-colored eruption lasting three days and then disappearing to be replaced by another crop. It resembled the characteristic eruption in that the spots disappeared upon pressure, but each spot remained an indefinite period varying from three to six days.

The third characteristic symptom is diarrhœa, the pea-soup discharges which appear during some period of the fever. The diarrhœa which had been spoken of had been mentioned as "characteristic discharges," but according to the definition heretofore given they were not characteristic, but simply such diarrhœa as occurs in most cases of fever.

Dr. Delafield had avoided one difficult point by saying the etiology of the disease is obscure, for the reason that investigation was exceedingly difficult, perhaps impossible, in very many cases. That brought us back again to the question, Is the fever which is prevailing in New York a disease of spontaneous origin, or does it depend

upon a poison which must be developed in a living body, must be discharged from that body, and must undergo certain changes in decomposing excrement before it is infectious? In other words, can true typhoid fever occur without a typhoid germ? Of course this is one of the most difficult parts of the history of the disease to investigate, and there is a great difference of opinion with reference to it. That cases of typhoid fever had developed in some of our hospitals there could be no question, and some of the wards in our hospitals are in a condition favorable to the development of typhoid fever if it is of spontaneous origin.

Dr. Loomis then gave a brief analysis of the cases which he had seen in his wards at Bellevue Hospital since the last week in September—Dr. Weldon, House Physician. The number of patients was 17; of these 13 recovered and 4 died. Of those who died the average length of time in the hospital was three days; of those who recovered thirty days, the longest fifty days and the shortest fifteen days. The highest elevation of temperature was $105\frac{3}{4}^{\circ}$ F.; the average elevation was $101\frac{1}{4}^{\circ}$ F. Eruption was present in 4 cases, diarrhoea in 4 cases, and constipation throughout the disease in 13 cases. Hemorrhage from the bowels occurred in 2 cases, and both patients recovered. Autopsies were made in 2 cases, and there were found ulcers in the small and also in the large intestine, and in one case the ulceration in the large intestine was much more extensive than in the small. Dysentery occurred in one case during the period of convalescence.

These cases led him to believe that he was to regard the fever now prevailing in New York either as a continued fever with typhoid symptoms, or else abandon the idea that there is anything characteristic of typhoid fever; that it is simply a continued fever, which may or not be spontaneous in origin, possibly may be contracted under certain circumstances, a fever without regular history, and that we have not in New York a specific typhoid fever with characteristic cause and history, and which is never to be produced except by contingent contagion. We must either take that position or conclude that the majority of cases reported by Dr. Delafield were not cases of true typhoid fever. That is, we are not having true typhoid fever in New York, unless it be in a few cases accidentally brought to us from without the city and from where, perhaps, typhoid fever may be endemic or indigenous. Certainly the disease, as it now presents itself, does not correspond with Liebermeister's description, nor does it correspond to the history of the old New England typhoid fever.

THE PRESIDENT asked Dr. Loomis whether or not it had been his practice to endeavor to overcome constipation when present.

DR. LOOMIS replied that he allowed the constipation to continue; but what he meant by constipation here was absence of diarrhoea, the patients having occasional evacuations from the bowels.

DR. F. P. KINNICUTT said: Sir William Jenner has suggested that a potent and not uncommon cause of constipation in typhoid fever is to be found in a *deep* ulceration of one or more of Peyer's patches. Large superficial ulcerations favor a catarrhal inflammation of the intestinal mucous membrane and consequently diarrhoea; a single *deep* ulcer can produce a partial or complete paralysis of the bowel and hence give rise to constipation. Other causes of constipation are a torpidity of the large intestine with rapid absorption of its fluid contents, or diminished secretion from the mucous membrane of the bowel. With the view of ascertaining the relative frequency of constipation, its association with a mild or severe type of the disease, and, if possible, its causes, he had carefully studied the histories of all the cases of typhoid fever treated in St. Luke's Hospital during the years 1882 and 1883. The cases admitted during the summer and autumn of the former year were almost without exception of a very severe type, as is indicated

by the death-rate. Twenty six cases were treated, with 17 recoveries and 9 deaths. There was constipation throughout the stay of the patients in hospital in 13 cases, constipation for a week previous to death in 2 cases. In 4 of the 9 cases of death there was diarrhoea throughout the attack, in 2 constipation, in 1 alternating diarrhoea and constipation. In the remaining 4 cases which recovered there was diarrhoea throughout.

There were autopsies in two cases in which there was diarrhoea, in two cases in which there was constipation. In the former, in one case there was perforation of the small intestine; in the second Peyer's patches were elevated but not ulcerated; the solitary follicles of the lower portion of the ileum showed very superficial ulceration. In this case the diarrhoea was *very profuse*. In one case of constipation there were several perforations in the lower portion of the ileum; in the second, numerous ulcers and one large, almost gangrenous, Peyer's patch.

During the corresponding months of 1883, 18 cases of typhoid fever were treated, with 14 recoveries and 4 deaths. There was constipation in 7 cases, no diarrhoea in 2 cases, diarrhoea in 9 cases. In 2 of the fatal cases there was constipation, in 2 diarrhoea. In the only autopsy, which was in a case in which constipation was well marked, there were several perforations in the lower portion of the ileum. So far as the above observations go, they would indicate that constipation in typhoid fever is always a positive evil; and he believed often of dangerous import to the patient. This fact has a practical bearing in our treatment. In his own judgment, laxatives, however mild, are contraindicated after the first few days of the disease. Small enemata are far safer, and will answer every purpose. Small enemata, frequently repeated if necessary, are safer than larger ones given at longer intervals.

He was convinced that *true* relapses are wholly independent of any error of diet or other imprudence. He was disposed to believe that in these cases we see a form of *relapsing* typhoid. May we not believe, as Da Costa has suggested, that a portion of the poison remains latent, to reappear later and produce its legitimate effects, as is observed in cases of malarial fever? The indications for the use of alcohol are often misleading. In certain cases its use diminishes the frequency and increases the force of the heart's action, lowers the temperature, quiets the restlessness, the tremor, and delirium, and produces sleep. In other apparently equally favorable cases for its employment, all the symptoms become distinctly worse during its use. Personally, he was disposed to withhold alcohol until the third week, unless especially indicated.

His belief is that a large proportion of cases of typhoid fever are most advantageously treated by simple rest in bed, quietude, abundance of fresh air, and a carefully regulated fluid diet. Medicinal agents, as a rule, are needed only for combating special symptoms.

DR. E. G. JANEWAY said it had been supposed and so stated that typhoid fever is more prevalent in New York than it was formerly. He believed, however, that such a conclusion was incorrect, because mortuary statistics obtained at the Board of Health, and extending over a number of years, showed that according to the population the mortality from typhoid fever had markedly diminished. In 1848 there were 223 deaths from typhoid fever; in 1855, 139, and with a population less than one-half of what it is now; in 1870, 422; in 1872, 264; in 1874, 275; in 1875, 347; in 1880, 241. Besides, many cases of typhus were mistaken for typhoid fever during some of these years. He therefore thought that the real mortality from typhoid fever was not increasing in New York, when the increase of population was considered.

Another point which had been made was that the typhoid fever seen here at the present time is not the disease as it exists abroad. Yet the lesions, as seen by observers who have witnessed autopsies in both coun-

tries, are identical. It seemed to him, therefore, that if the lesions were identical we must look for the cause of the discrepancy, if there be any, in some other direction. The treatment, to some extent, furnishes one cause of the apparent discrepancy between the descriptions given by foreign writers and the histories of cases seen in our public institutions in New York. The influence of the quinine which patients almost invariably either take of their own accord or have prescribed for them early in the disease, must be taken into consideration in studying the subsequent progress of the affection. More than that, both Liebermeister and Murchison admit that there are atypical as well as typical cases. Dr. Janeway had seen typhoid fever in institutions in New York where a large number of patients were attacked at about the same time, and he had noticed, and the same thing has been observed in London, that the course of typhoid fever varies according as it occurs in children or in adults. At the Deaf and Dumb Asylum four outbreaks had occurred, the number of cases varying from fifty to seventy. At the Catholic Half-Orphan Asylum seventy of the inmates were attacked with typhoid fever within one month. In these two places the symptoms differed materially, and yet at autopsies made at both places the lesions were those of true typhoid fever. In the Deaf and Dumb Asylum the symptoms were those most commonly present in typhoid fever, such as nose-bleed, diarrhoea, etc.; while in the Catholic Asylum out of seventy cases diarrhoea occurred in only eight; only four patients had the eruption, and it appeared early in the disease.

The outbreaks in both of these institutions were of short duration. Dr. Janeway wished to direct special attention to this fact, namely, that typhoid fever is not necessarily a disease of three, five, or six weeks' duration, but a disease due to a poison which may produce symptoms lasting from three days to six or more weeks. In each instance, whether of short or long duration, the existence of the disease had been proved by autopsies. During the present autumn he did not recall a single case, occurring in an adult, in which the eruption was not present, and he thought that if the abdomen, the chest, and the back were closely inspected the eruption would in most cases be found within the first ten days of the disease. He had seen a number of cases in which the disease was contracted in the country, but had not seen that the lesions differed essentially from those found in cases having their origin in the city. It seemed to him that the typhoid fever in New York was like that which occurred in other localities and other countries.

It is difficult and sometimes impossible to determine the etiology of the disease in a certain case or group of cases. Dr. Janeway cited a case, that of a pedlar, who for a week had a diarrhoea, during which time he was at work, and when he wished to have a movement from the bowels used the privy vault of the nearest tenement-house. The case simply illustrated the possibilities concerning the propagation of the disease.

With regard to transmission by milk, the work in that direction in New York had been extremely unsatisfactory. Defective sewerage has also been found in localities where typhoid fever developed, but it is difficult to prove that the disease was caused by such imperfection, although it might give rise to a very strong suspicion.

DR. T. A. McBRIDE limited his remarks to cases seen at the Out-patient Department of New York Hospital, and to certain points in the treatment of typhoid fever. When a patient presents himself at the Out-patient Department with a diarrhoea he always takes his temperature, and almost invariably finds it elevated. He also has him stripped and finds an enlarged spleen, often some enlargement of the liver, and nearly always spots of the eruption of typhoid fever. Some of these patients are sent to the hospital and remain there for a long time, but many of them are not sick longer than from seven to ten or, at most, fourteen days. He had regarded such as mild cases of typhoid fever. They seemed to be

very common, especially among people who go to dispensaries.

Recently he had had a patient who had a number of hemorrhages from the bowels, and he would ask Dr. Delafield how soon albumen appears in the urine and how long it continues. According to his observation in such cases, Dr. McBride believed that when excessive hemorrhage occurred from the intestines albumen almost invariably existed in the urine, unassociated with tubercasts or other elements of the kidney. What he wished to direct especial attention to was a point in the treatment of typhoid fever. It was with reference to the use of *kairin*, a remedy which he first employed in May last. During this autumn he had had several opportunities to use it. In one case the patient was unable to take quinine, whether in capsule, compounded with agents to prevent head symptoms, or otherwise, and with very satisfactory results. In this particular case fifty or sixty grains of kairin were administered in twenty-four hours.

The rule he had adopted, however, concerning its use was the following: When the temperature has reached 103° or 104° F., give *seven* grains of kairin every hour until the temperature falls to 101° F. If the temperature is 102° F., give only three and a half grains every hour until the temperature falls to 101° F. In every case the seven grains had reduced the temperature from three-fourths to one degree, and it had been seldom necessary to use it more than two hours in succession. Almost invariably the remedy produces profuse perspiration. Kairin simply reduces temperature, but it does not remain so and will rise again in the latter part of the day in a case of typhoid fever as soon as the use of the drug is discontinued. Therefore having lowered the temperature to 101° F., have the record made every hour, and on the slightest elevation above that point administer three and a half grains every two hours. He limited the reduction to 101° F., because if carried beyond that degree the patient is very liable to have a chill. When the rule given had been observed he had not seen a case in which a chill occurred, nor had he observed any depressing effect produced on the heart. The mode of administration had been by either capsule or pill. The urine assumes a greenish color while the patient is taking kairin, and contains a small quantity of albumen but none of the elements of the kidney.

DR. JANEWAY remarked that kairin had been recommended in much larger doses than those mentioned by Dr. McBride.

DR. McBRIDE said he had employed fifteen-grain doses, but the temperature was brought down too quickly, and fearing that a chill might be produced he had used it in smaller doses and with equally satisfactory results.

DR. KINNICUTT said that in some cases recently observed he had found it necessary to continue the drug from seven to ten hours to keep the temperature down.

DR. McBRIDE remarked that he had not seen any ill results follow the use of kairin for several days in succession.

DR. H. PINKNEY recalled a paper written by a physician in Milan twenty-three years ago, who made a number of experiments by introducing poison into animals, and succeeded in producing all the results of typhoid fever; and by using the sulphite of soda, either mixing it with the matter introduced or giving it internally, he was able to counteract the effects of the poison. For fifteen years he had used sulphurous acid successfully, apparently so at least, in typhoid fever.

DR. J. H. FRUITNIGHT had during six months met with thirty cases of typhoid fever. In twelve the disease pursued a very regular course, and two of these were especially interesting. One occurred in a woman advanced three months in pregnancy, and terminated fatally. The other in a woman who had just been confined, but the patient recovered. Among the twelve there were three in which relapses occurred, but all the patients recovered. Four patients had hemorrhage from

the bowels. Two cases terminated fatally; one on the fifth day with active delirium and a temperature at 105° F., and the other in the third week from exhaustion.

DR. A. C. POST asked if in the cases attended with constipation or absence of diarrhœa there was pain, tenderness, or gurgling in the right iliac fossa.

THE PRESIDENT remarked, concerning the use of laxatives in cases with constipation, that it had been his custom never to disturb the bowels by any medicinal treatment unless the patients complained of discomfort, and in such cases he had given a single dose of *five* grains of calomel with fifteen or twenty grains of carbonate of soda, which produces free evacuation without pain, and he had always felt that it was of great benefit.

DR. DELAFIELD, in closing the discussion, said that Dr. Loomis had spoken somewhat forcibly of the atypical character of the typhoid fever in New York, so atypical that he feels disposed to deny it even the name of typhoid fever. The fact that a disease does not always present its regular symptoms is something which is well known. And the fact that this disease does present itself in a somewhat atypical form was one reason why he thought it worth while to bring together the symptoms of a certain number of cases.

After all, this behavior of typhoid fever is the same as the behavior of many other infectious diseases, and as they occur in different places and at different times they present themselves with different degrees of development, both with regard to lesions and symptoms. Typhoid fever, as it has existed in New York during the last few years, has not been strongly developed as regards the morbid anatomy, but when the lesions are compared with those developed in other epidemics it is easy to see that they are the same in kind, although they may differ very much in degree. The same is true of the symptoms, although they have not been nearly as pronounced as they have been in some other epidemics. But if this is true of typhoid fever, it is equally true of many other infectious diseases, and Liebermeister, the author to whom Dr. Loomis had referred, was a writer who had misled a great many people. The article written by him and published in Ziemssen's "Cyclopedia" Dr. Delafield translated, and at the time became convinced that it was evidently made up of descriptions more definite and more decided than any descriptions can be possibly which are taken from nature. The author has evidently suppressed the truth to some extent in his desire to be positive, decisive, and clear.

Dr. Kinnicutt had spoken of the existence of constipation. Constipation unquestionably does exist in a fair proportion of cases, and by the word Dr. Delafield meant not only the absence of diarrhœa but real constipation. The condition apparently does not have anything to do with either the size or the number of the ulcers in the small intestines. This also is analogous to what is found in phthisis, where very often tubercular ulcers are developed in the small intestines, sometimes accompanied by diarrhœa, sometimes not, and the size and number of these tubercular ulcers do not have any direct relation to the amount of diarrhœa the patient has. In fact, he thought it was doubtful whether lesions of the small intestines produce diarrhœa; whether we do not have to look for other causes than these lesions.

It seemed to him that constipation is a real evil, and during the first week he saw no reason why a moderate laxative could not be given with safety and benefit, and he regarded it better to give a mild laxative than allow the colon to become filled with fecal matter. Later in the disease enemata are preferable.

Dr. Delafield agreed with Dr. Kinnicutt in the view that relapses are due to the disease itself rather than to any accidental circumstances.

With reference to the fact to which Dr. Janeway had called attention, namely, that when in any large institution a number of persons are attacked there will be some of whom it cannot be said that they have typhoid

fever at all, this is a fact which cannot be questioned. It has been observed a great many times in other infectious diseases, as well as in typhoid fever, that the poison of a disease, whatever it may be, is capable of producing the characteristic disease, and also other disorders more or less like the real disease.

As regards the eruption, Dr. Janeway's experience seemed to be like his own—namely, that it is more constant in patients this fall than it has been before, and especially within the last six weeks.

With regard to the coincidence of albumen in the urine and hemorrhage mentioned by Dr. McBride, he had had no experience. Changes in the kidney are the rule in typhoid fever, and albumen in small quantity, as the result of these changes, exist in the urine in some cases, but not all. The kidney lesion can exist without albumen being present in the urine. The quantity of albumen in all the cases which he had seen had been small, ranging from a trace to five or ten per cent.

In some cases casts were found, in many there were none, and yet the lesion had been fresh parenchymatous nephritis.

In answer to Dr. Post's question, Dr. Delafield said he thought there was gurgling and tenderness over the caput coli in cases of constipation. Although he had no statistics on that point he could at once recall several cases in which the two conditions were associated.

The Academy then adjourned.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, October 24, 1883.

GEORGE F. SHRADY, M.D., PRESIDENT, IN THE CHAIR.

DR. CHARLES HEITZMAN presented a specimen of

MELANOTIC MYELOMA OF THE CHOROID,

for which he was indebted to Dr. H. O. Farnham. It came from a Boston gentleman, sixty years of age, whose left eyeball was enucleated on account of a tumor of the choroid, diagnosed by the ophthalmoscope. A few months after the operation the liver began to swell, obstinate coughing set in, and the patient died with symptoms of exhaustion. At the post-mortem melanotic tumors were found in the lungs, the liver, and the spleen.

On microscopic examination the primary tumor proved to be a melanotic myeloma of the choroid, the size of a sugar-pea, having at its periphery destroyed the retina, and invading the vitreous body. It was a combination of so-called "large round and spindle celled sarcoma," all elements being crowded with dark red-brown pigment granules.

The point of interest lay at the peripheral portion of the tumor, which was ensheathed, toward the vitreous body, by a delicate, though distinctly marked capsule of fibrous connective tissue. The zone of the vitreous body nearest to the capsule was crowded with yellowish, globular, highly refracting corpuscles, greatly varying in size, but nowhere reaching the diameter of red blood-corpuscles. These corpuscles proved to be juvenile forms of living matter, which the speaker, in 1872, and Hayem, of Paris, several years later, termed "hæmato-blasts." All stages of development toward pigmented large elements of myeloma were traceable, the same as the formation of clusters of pigment from the hæmato-blasts. From the fact that such gradual changes of forms were seen in the vitreous body, from the small homogeneous globule, not endowed with properties of amoeboid change or locomotion, up to the fully developed reticular and pigmented myeloma element, the conclusion must be drawn that these elements have originated in situ, in the vitreous body itself, from the living matter therein concealed. This is a strong proof of the assertion that the vitreous body is not a mere mass of mucus, but a regular living tissue, of the myxomatous variety of the connective tissue.

DR. A. JACOBI asked, Is it a tumor by itself?

DR. HEITZMAN said that it was independent so far as migration of cells were concerned, such spread being prevented by the capsule, which was unaffected.

DR. JACOBI asked, Is there lymph connection between the choroid and the interior of the eye in the direction of the vitreous body? If so, it is not necessary that there should be an independent sarcoma. For it was easy to imagine that sarcomatous cells might pass through lymphducts, which are apt to be open, and that might explain the apparent independence of the growth, while in reality it belonged to an original body.

DR. HEITZMAN said that but little was known as to the lymphatics of a sarcomatous growth, and to be sure the lymph-passages in this specimen, as well as toward the vitreous body, were scanty, the same as were the blood-vessels. But that was not the main point in his argument, as within the vitreous body itself could be seen bodies which illustrated all the different stages in the transition from a simple globule to the red blood-globule.

DR. HOWE thought there were small cells in the fibrous tissue.

DR. HEITZMAN regarded them as upon the fibrous tissue, having been drawn there by the razor when the section was made. Besides, it is known that red blood-globules are solid and never migrate. The capacity for motion manifests itself with the development of the reticulum of living matter.

EXTIRPATION OF THE KIDNEY.

DR. W. GILL WYLIE presented a kidney removed by abdominal section in August last. The patient was sent to him by Dr. Winters, of Phœnicia, and gave the following history: She was thirty-four years of age, the mother of four children, and had had one miscarriage. So far as she knew, all the members of the family had been regarded as healthy. At the age of fourteen she had what was said to be pneumonia, but further than that there was no evidence of pulmonary disease. During the last eighteen months she had been treated for supposed uterine disease. There was no evidence, however, from either physical examination or clinical history, that she was then suffering from either ovarian or uterine disease or disease of the Fallopian tubes. The chief symptom was pain in the right side, and sometimes painful menstruation. The pain during the last eighteen months had been very severe at times, especially after walking or other exercise, and finally became spasmodic and so intense that morphine at first, and later chloroform, were required to relieve the suffering, which was confined to the right side. The patient was examined while lying upon her back, and nothing could be made out by palpation except that the abdominal walls were lax, but as she sat up and twisted her body he felt a tumor just below the liver, and it seemed to be the kidney with its long axis at right angles with the long axis of the body. Dr. Wylie diagnosticated movable kidney, believed that the probabilities were in favor of its becoming strangulated, and recommended that it be removed. For a long time there had been steadily pus and albumen in the urine, and Dr. Winters had reached the conclusion, several months before Dr. Wylie saw the patient, that it was a case of loose kidney. About one week subsequently Dr. Wylie operated for its removal by making an incision through the abdominal walls, just to the right of the umbilicus, sufficiently large to admit the ends of the fingers, with which he was able to determine that the ovaries and uterus were normal, the intestines, the liver, and the gall-bladder also were apparently normal, and the left kidney was in its normal position.

The right kidney was not readily found, but that was accounted for by the position of the incision, for when the patient was placed in the upright position the organ twisted upon its attachments, so that its long axis was at right angles with the long axis of the body and it was

at once detected. By having the edges of the wound held apart by tractors, Dr. Wylie was able to get one finger above and another below in such a manner as to push the kidney forward without much trouble, and then toward the right side. An incision two or three inches long was then made in the peritoneum, the upper end of the kidney was pushed through, and the entire organ followed without difficulty. The ureter was tied, leaving behind a portion about two inches long; the arteries were ligated and then the two were tied together and the whole mass cut off. The stump was dropped back. The abdominal wound was closed with sutures and dressed, and the patient was left in the care of Dr. Winters. No bad symptoms occurred for nine days, and during that time the average daily discharge of urine was twenty-four ounces. Dr. Winters removed the stitches on the eighth day but did not put on any supporting adhesive straps; the patient burst the wound open and lost sufficient blood to place her in a rather unpleasant condition. An abscess subsequently formed in the abdominal walls at the site of the incision. At the present time thirty-six ounces of urine are discharged daily, and the patient is dressed and about her room some. There is yet pus in the urine, and for the first time the patient has complained of considerable pain in the left side. Dr. Wylie thought the chances were that the left kidney was not perfectly healthy. The kidney removed had been examined by Dr. W. H. Welch, who reported that it was tuberculous and that he found the tubercle bacillus. His diagnosis was primary urino-genital tuberculosis.

DR. A. JACOBI said, to avoid any mistake, he would like to have Dr. Wylie state that he does not consider the existence of floating kidney by itself an indication for its removal.

DR. WYLIE said certainly he would not regard it as proper to remove a kidney simply because it was a floating kidney; but in this case he was inclined to regard it as a dislocated kidney, for the peritoneal tissues are not so lax normally as he found them.

DR. JACOBI said he requested Dr. Wylie to make that statement, and wished to have it put on record, as certainly he should not wish to be understood as favoring any such therapeutical indication. Surely the existence of floating kidneys is no indication whatsoever for their removal. In Dr. Wylie's case there was more than a probability that the kidney was diseased. Floating kidney is not rare. Vollet has published a large number of cases, almost exclusively in women and upon the right side, and many of them in children.

DR. JACOBI had seen at least thirty cases of floating kidney, chiefly in women who have borne children: a few in children, and also in the adult male.

DR. WYLIE thought that not much could be done in cases of floating kidney by the use of bandages or pads. If pus is found in the urine, even if there is not much discomfort the case should be carefully watched, and if it increase and there was a probability of the occurrence of anything like an abscess, we should operate at once.

DR. HEITZMAN said that he had made three hundred post-mortems in which he found tuberculous kidneys, and in only four was there croupous nephritis and necessarily casts in the urine, whereas in all the other cases there was interstitial or catarrhal nephritis. Tuberculosis of the kidney as a primary lesion is extremely rare. He thought there need be no difficulty in deciding whether or not the other kidney is involved, because as soon as renal epithelium appear in the urine the fact is established that the organ is in an inflamed condition.

STRANGULATED HERNIA—GANGRENE OF THE INTESTINE—ENTEROTOMY.

DR. JOSEPH W. HOWE presented a specimen of gangrenous intestine, removed from a patient in St. Francis' Hospital, who gave the following history:

Adam G—, aged forty-three; occupation, baker;

has had a hernia for thirty years. It gave him little or no trouble until Friday, October 19th, when, during an attack of coughing, he felt a sudden pain in the region of the hernia, which at once became painful and increased in size. Soon afterward he became sick at the stomach, vomited, and was unable to have a movement from the bowels. He was admitted to the hospital on Tuesday, October 23d, in a state of collapse. He complained of pain over the whole abdomen, and vomited small quantities of stercoraceous material. The swelling in the groin was red, tympanitic, and very painful to the touch. Stimulants and morphia were administered, and at 8 P.M. Dr. Howe operated. When the sac was opened the principal portion of the intestine forming the hernial protrusion was found to be gangrenous, and on the inner side of the hernia there was a rupture, which had evidently been made during attempts at reduction. The gangrenous intestine was cut away and the edges of the gut stitched to the integument, making an artificial anus, which Dr. Howe stated would probably never be used, as the patient was then in a dying condition.

The case was presented as an addition to the already large number of cases of strangulated hernia so frequently sent in a dying state to our hospitals by men who seemed to be ignorant of the affection.

DR. VAN SANTVOORD presented a specimen of

STENOSIS OF THE PULMONARY ARTERY,

due to contraction and thickening of the semilunar valves. It was taken from the body of an infant that died at Randall's Island Asylum twenty days after birth. The child was fairly well developed, but had rapid respiration and pulse. Physical examination revealed a loud blowing murmur over the entire chest, loudest to the left of the sternum, at the junction of the third and fourth ribs. At that time the child was not cyanotic, but cyanosis developed gradually, and in the course of a few days it died of cardiac failure.

At the autopsy the semilunar valves of the pulmonary artery were found markedly thickened and contracted, and he thought the tricuspid valve was also somewhat affected. The ductus arteriosus was widely open and lined with a deposit of fibrine. There was also marked hypertrophy of the right ventricle, its wall being nearly as thick as that of the left ventricle. The other organs were normal, except the kidneys, which were slightly congested. The inter-ventricular septum was perfect, and the foramen ovale was patulous to the same extent as is usual in a child of this age.

DR. A. JACOB thought the nearly equal thickness of the walls of the ventricles was about normal at that period of life. The fact that there was contraction of the valves and not stenosis of the pulmonary opening would indicate that an inflammatory process had existed, and especially as the tricuspid valve was also somewhat involved. He thought it quite probable that endocarditis had occurred during the latter part of pregnancy.

DR. VAN SANTVOORD thought endocarditis was the probable genesis of the case, for the most part at least. He was not quite certain concerning the condition of the tricuspid valve. The hypertrophy of the right ventricle was certainly marked, and he thought that, at the age of twenty days, there is a notable difference, normally, in the development of the two ventricles.

DR. F. FERGUSON presented two specimens of

RUPTURE OF THE HEART.

A male, about fifty years of age, a native of Germany, died suddenly at his own residence, in Brooklyn, the first week in October, 1883. He was well up to within a few hours of his death, when he suffered from an attack of dyspnoea which lasted a short time. Two hours after his dyspnoea subsided he had occasion to use the water-closet, where he was found dead.

The post-mortem examination was made by A. H. P. Leaf, Pathologist to St. Mary's Hospital, in Brooklyn,

through whose kindness he received the specimen. The body was well nourished; no marks of violence, and no cedema was present. The peritoneum was normal. The stomach and intestines were normal. The spleen was larger than normal and pigmented. The kidneys were markedly atrophied, their surfaces very granular; cortices were pervaded by numerous small cysts. The tubes of the cortex contained considerable fat and hyaline casts. There were numerous hyaline and granular casts in the tubes of the pyramids, more especially near the apices. The interstitial tissue was markedly increased, many of the glomerules being converted into solid globes of fibrous tissue. The renal vessels were everywhere thickened. The lungs were congested and cedematous. The pericardium was distended with blood. The heart was normal in size. Its muscular tissue was brownish, and its valves were competent. The endocardium was everywhere thickened. There was a linear rupture in the anterior wall of the left ventricle, beginning at a point one and one-half inch above the apex, and extending upward three-fourths of an inch. At the site of the rupture the ventricular wall was about one centimetre in thickness. There was increase in the fibrous tissue and fat in the muscular wall of the ventricle, and the muscle-cells were deeply pigmented.

Dr. Ferguson also presented a specimen of

RUPTURE OF THE HEART IN TETANUS.

A male, forty-four years of age, married, a native of Ireland, and a glazier by occupation. On September 7th last he sustained an injury to his left hand, tearing away the soft parts from its dorsal aspect and exposing the extensor tendons. His injury was dressed antiseptically, and for three weeks he did well; at the end of that time, however, he experienced stiffness and rigidity of the muscles of the face and neck, giving rise to retraction of the head; soon after he was seized with convulsions, which became more frequent and more severe in character until October 13th, when during a convulsion he suddenly died. He had opisthotonos during his convulsions, and suffered greatly from dyspnoea. He was in the hospital only five days, and during that time he could not separate his jaws more than one-fourth of an inch. His pulse was full, strong, and regular, varying from 80 to 90 beats a minute. His temperature ranged from 99° to 101.6° F., and his respiration 40 to 50 a minute. He was treated with fluid extract of physostigma.

On autopsy the brain and cord were found intensely congested. The organs in the abdominal cavity were normal. The lungs were congested and cedematous. The pericardium contained 100 cubic centimetres of pure blood. The cavities of the heart were dilated. The ventricular walls were thin, and the muscular tissue was brownish. The valves were competent; there were a few small patches of atheroma in the segments of the mitral valve. In the anterior border of the heart, one inch to the right of the apex, was a circular opening which admitted a probe one-eighth of an inch in diameter. The right ventricular wall surrounding this opening was about a line in thickness. The muscle-cells of the heart were normal.

DR. H. D. CHAPIN presented a specimen of

PERI-ESOPHAGEAL ABSCESS—CARIES OF THE SPINE, accompanied by the following history:

Mary D—, aged two years and eleven months, was brought to him at the Out-door Department, Bellevue Hospital, September 5th. She had pertussis five months ago, and the mother said she had had bronchitis ever since. On examination she was found to have a slight difficulty in breathing, but not amounting to dyspnoea. On auscultation nothing was heard but tracheal and laryngeal râles. Temperature normal. Nothing was visible in the throat. The child was well nourished and had no rachitic appearance, although she was eleven months old before getting

her first tooth. She came once a week for the following month, and seemed to improve under tonic treatment. The peculiar sounds on inspiration and expiration continued present. The temperature never rose above the normal. There was never any dysphagia. The voice was not at all affected. In the evening of October 10th, after eating a hearty supper, she began playing with her mother, laughing frequently. She was suddenly attacked by a fit of coughing, which was followed by intense dyspnoea, lividity of the face, and death.

Autopsy.—Body well nourished. A large abscess was found back of the œsophagus, within and in front of the first and second dorsal vertebrae, which were deeply carious. The trachea was injected and covered by muco-pus, and had small miliary tubercles in it. Miliary tubercles were also found in the lungs. A large cheesy bronchial gland was found, between which and the sac of the abscess the right pneumogastric nerve was apparently pressed upon just where the cardiac nerves were given off. Just above this point the right vagus seemed somewhat swollen.

DR. W. M. CARPENTER, in behalf of Dr. J. W. Stickler, presented a specimen of

SCIRRHOUS CARCINOMA OF STOMACH, INVOLVING THE LIVER, INTESTINE, AND SPLEEN.

Adam S—, aged fifty-two, native of Germany. No history of cancer in family. Patient was perfectly well up to fifteen months ago. At that time he complained of quite severe pain in the left hypochondrium, but had no fever or organic disease that could be discovered. Palpation revealed no tumor in abdomen. Bowels were somewhat costive; micturition normal. Under the influence of anodynes and counter-irritants he improved somewhat, but was never entirely free from pain, which gradually extended to the right hypochondrium. He rapidly emaciated, having but little appetite, and repeatedly vomited the food taken. There was, however, no vomiting of either pure blood or chocolate-colored matter. This condition would last about one week, to be followed by nausea; then the vomiting would recur, and in this manner the alternation was maintained till death. The bowels became very constipated and urination very frequent, painful, and scanty. Chemical and microscopic examination at that time revealed nothing abnormal. Retention of a very small quantity of urine, beginning about six weeks before death, necessitated the frequent use of the catheter. The severe pain had now extended to every region of the abdomen and the emaciation became extreme. There was also a very manifest cachexia. Physical examination disclosed a tumor, hard and irregular in outline, in the region of the pyloric end of the stomach, although nothing positive could be ascertained with reference to the other abdominal organs. Death from exhaustion finally supervened, fifteen months from the date of the first attack of abdominal pain. At the post-mortem I discovered the following condition: The cæcum was bound to the inner surface of the abdomen by strong fibrous bands, and so much constricted that it seemed improbable that any fecal matter had passed through it prior to death. The transverse colon was drawn down and attached to the ascending colon, and it was also attached to the gall-bladder and spleen. The liver was small and quite firm in consistence, and attached to the spleen by broad fibrous bands. The œsophagus apparently lay between these two organs, and was firmly adherent to them. The stomach was below and behind the liver, and much smaller than normal. Its anterior wall was greatly thickened, especially that portion of it nearest the pyloric end of the organ. The interior of the viscus presents fibrous bands connecting opposing surfaces, also various sacculations. The kidneys presented nothing abnormal macroscopically, except quite intense congestion. A microscopic examination of a portion of the morbid growth revealed many of the characteristic features of a scirrhus carcinoma.

DR. J. C. PETERS made a verbal supplementary report on

EQUINE SCARLET FEVER,

after which the Society went into executive session.

Correspondence.

TYPHOID FEVER AND MILK.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: There have been here during the past two or three weeks, in one locality comprising three or four blocks, ten cases of continued fever—three adults, the rest children under ten years of age. Four of the cases (two of adults) assumed a typhoid character.

Investigation showed that all of the families received their milk from one milkman, in whose house had been one of the typhoid cases for four or five weeks. The milk was stopped in all cases; all are recovering. In one of the typhoid cases there was marked improvement within forty-eight hours after stopping the milk. It was noted that several other children in the neighborhood not supplied by this milkman remained well. It seemed settled in the community that the disease was propagated through the milk.

But now, on the other hand: 1. The patient in the house of the milkman was in an upper room of an adjoining wing to the house, and had been free from fever for ten days or more previous to inception of the disease by some of the others. 2. The milk was not brought into the house proper at all, but into the cellar, where it was at once measured and sent out by a man who had no contact with the patient. Consequently the milk was not on the premises but a very short time. 3. The cellar was perfectly clean and well ventilated, and had no interior communication with the house. Is entered from outside only. 4. The cows were all healthy, in good condition, and fed only on the best of food. No slops of any kind. 5. I examined the well-water in which the milk vessels were washed, chemically and microscopically, and could detect nothing abnormal. Besides, the well was cleaned a few weeks ago.

There is no cesspool on the premises, and the out-house is far away from the well. In addition, some of the sick children had never drank the milk, but had used a little on oatmeal or hominy. Again, the number sick was only a portion, a small percentage, of those supplied by the same milkman who have remained well while still continuing use of the milk. And finally, the disease prevails more or less throughout the town in other localities where this milk was never used. In the adjoining street there were nearly as many cases as those cited.

The one patient whose improvement was coincident with stopping the milk had reached the fourteenth day, the period when most of the cases began to convalesce. From all which I find myself unable to establish any connection between these cases and the milk-supply, *unless possibly* in the fact that the woman who gave care in part to the patient in the house also washed the milk vessels, using *hot* water first, then cold.

My own judgment is against the conclusion. May I beg the favor of the Editor's opinion in the matter, which has interested our entire community, and oblige,

Respectfully,

D. A. BALDWIN, M.D.

ENGLEWOOD, N. J., November 13, 1883.

[We fail to see any direct connection between the milk-supply and the cases of fever.—ED.]

OIL OF BIRCH AND OIL OF WINTERGREEN.—According to Mr. G. W. Kennedy (*New Remedies*), the oil of wintergreen of the shops is really in large part oil of birch. Chemically and physically the two oils are very nearly identical, so that the adulteration is harmless.

New Instruments.

A NEW STYLE OF FORCI-PRESSURE FORCEPS OR ARTERY CLAMPS.

By JAMES L. LITTLE, M.D.,
NEW YORK.

THE accompanying cut shows a new style of artery clamp which has been made for me by Mr. Ford, of Caswell, Hazard & Co.

I do not doubt that of late years all surgeons have been in the habit of using some style of clamp to control the hemorrhage from small vessels during the progress of an operation, thus saving themselves the delay of tying. I have been in the habit of thus controlling hemorrhage for some years past, but owing to the narrow blades and slim points of the clamps now in use, have never been able to find one that would allow of the tying of the vessel without first removing the clamp and seizing the bleeding point again with an ordinary pair of "bull-dog" forceps. I found that there was always more or less blood lost in this way, which I concluded could be saved by combining both clamp and artery forceps in one instrument, and I have been so well satisfied with the result of the experiment that I have thought it worthy of presentation to the profession.

Army and Navy News.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from November 10 to November 17, 1883.

BACHE, DALLAS, Major and Surgeon. Ordered to report in person to the commanding general Department of the East for assignment to duty. S. O. 259, par. 10, A. G. O., November 12, 1883.

GARDINER, J. DE B. W., Captain and Assistant Surgeon. Relieved from duty at Fort Huachuca and assigned to duty as Post Surgeon at Fort Bowie, A. T. S. O. 104, par. 1, Department of Arizona, November 8, 1883.

EGAN, PETER R., First Lieutenant and Assistant Surgeon. Upon being relieved from duty at Fort Bowie, A. T., to proceed without delay to Fort Huachuca and report to the commanding officer at that post for duty. O. 104, par. 1, Department of Arizona, November 8, 1883.

Official List of Changes in the Medical Corps of the Navy, for the week ending November 17, 1883.

HALL, C. H. H., Passed Assistant Surgeon. Ordered to the Naval Academy, Annapolis, Md.

HOW TO TAKE TINCTURE OF IRON.—To disguise the taste of tincture of iron, Dr. Haner recommends that tincture of the sesquichloride of iron be mixed with simple syrup, and then with milk. This mixture will not affect the teeth, nor will the styptic taste be apparent.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending November 20, 1883:

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
<i>Cases.</i>								
November 13, 1883.....	1	50	67	3	22	43	0	0
November 20, 1883.....	0	32	44	1	51	39	1	0
<i>Deaths.</i>								
November 13, 1883.....	1	21	8	1	1	23	0	0
November 20, 1883.....	0	13	9	1	6	22	0	0

A FORMULA FOR IRREGULAR HEART-ACTION.—In a discussion upon heart disease before the Boston Society for Medical Improvement, Professor Bowditch said that he had found the following formula of great service in relieving even serious cardiac affections: Pulv. digitalis, gr. x.; pulv. colchici sem., gr. xx.; sodi bicarbonatis, gr. xxx. M. et div. in pil. no. xx. These are to be taken three or four times daily at first, subsequently to be reduced until only one is taken at bedtime. The treatment to be continued for three to nine months.

AN EASILY ADJUSTABLE HANDLE FOR THE LARYNGOSCOPIC AND RHINOSCOPIC MIRROR, as well as laryngeal probe, is the ordinary automatic pencil-holder made by the Eagle Pencil Co., and sold by stationers generally. The handle of the mirror is held in place in the same manner as the lead, and can be lengthened or shortened by pressure on the spring at the end of the holder. After several months' trial it has been found most satisfactory, from its smoothness and the short time required to adjust it.—*Philadelphia Polyclinic.*

FRAUDULENT ADVERTISEMENTS.—The Denver *Inter-Ocean* discourses with emphasis upon the subject of patent medicine and other advertisements. The editor says: "We like to fill our columns with good advertising, and we believe that we give our patrons dollar for dollar. We have no desire for fraudulent advertisements, or for advertisements that discuss queer diseases. We threw out Lydia Pinkham's chromo because the agents unjustly claimed nine fowls in twenty-five insertions. We do not stand that sort of discount. . . . We are not advertising piles! piles! piledrivers, lost manhood, or lewd shows; and we are not booming torpid livers in our fashion column. We are not giving the nostrum quacks cheap advertising. They must pay us what home advertisers pay. To charge home advertisers full rates, and then to give space to Eastern patent medicines for less money, isn't our idea of honesty."

MATRIMONIAL ENGAGEMENTS AND UTERINE POLYPI.—The defendant in a recent breach of promise case in Mercer County, O., based his defence on the fact of the development of a fibrous polypous tumor in the uterus of his betrothed. This would seem to be a valid excuse for a man's not marrying a woman, but the plaintiff claimed that the growth was produced by and resulted from the protracted courtship, causing her to brood upon the prospects of entry into married life. It was proved by experts that prolonged courtship is harmful, superinducing a condition of erethism, and the jury awarded the plaintiff a verdict of \$3,000 as a balm for her wounded feelings and polypoid uterus.—*Medical Age.*

CEREBRO-SPINAL FEVER.

(SPOTTED FEVER. CEREBRO-SPINAL MENINGITIS.)

By J. LEWIS SMITH, M.D.

CLINICAL PROFESSOR OF DISEASES OF CHILDREN, BELLEVUE HOSPITAL MEDICAL COLLEGE.

(Continued from p. 561.)

Symptoms.—During the prevalence of cerebro-spinal fever cases now and then occur in which the symptoms are mild and transient, and the health is soon fully restored. It seems proper to regard some, at least, of these as genuine but aborted forms of the disease. The following cases which occurred in my practice may be cited as examples :

A boy, eight years of age, previously well, was taken with headache, vomiting, and moderate febrile movement, on April 2, 1872. The evacuations were regular and no local cause of the attack could be discovered. On the following day the symptoms continued, except the vomiting, but he seemed somewhat better. On April 4th the febrile movement was more pronounced, and in the afternoon he was drowsy and had a slight convulsion. The forward movement of the head was apparently somewhat restrained. On the 6th the symptoms had begun to abate, and in about one week from the commencement of the attack his health was fully restored.

A boy, aged six, was well till the second week in May, 1872, when he became feverish and complained of headache. At my first visit, on May 14th, he still had headache, with a pulse of 112. The pupils were sensitive to light, but the right pupil was larger than the left. The bromide and iodide of potassium were prescribed, with moderate counter-irritation behind the ears. The headache and febrile movement in a few days abated, the equality of the pupils was restored, and within a little more than one week from the commencement of the disease he fully recovered.

These cases occurred when the epidemic of 1872 was at its height ; but if the symptoms are so mild, and the duration of the disease short, as in these two cases, the diagnosis must sometimes be doubtful. Observers in different epidemics report similar cases, and as the symptoms, so far as they appeared in my patients, seemed characteristic, I have not hesitated to regard them as genuine but aborted cases. On such patients the epidemic influence acts so feebly, or their ability to resist it is so great, that they escape with a short and trivial ailment.

Occasionally, also, during the progress of an epidemic we meet patients who present more or fewer of the characteristic symptoms, but in so mild a form that they are never seriously sick, and never entirely lose the appetite, but the disease, instead of aborting, continues about the usual time.

Thus, on January 4, 1873, I was called to a girl aged thirteen, who had been seized with headache followed by vomiting in the last week in December. During a period of six to eight weeks, or till nearly March 1st, she had the following symptoms : Daily paroxysmal headache, often most severe in the forenoon ; neuralgic pain in the left hypochondrium, and sometimes in the epigastric region ; pulse and temperature sometimes

nearly normal, and at other times accelerated and elevated, both with daily variations ; inequality of the pupils, the right being larger than the left during a portion of the sickness. The patient was never so ill as to keep the bed, usually sitting quietly during the day in a chair or reclining on a lounge, and she never fully lost her appetite. Quinine had no appreciable effect on the fever or paroxysms of pain. There can, in my opinion, be little doubt that this girl was affected by the epidemic, but so mildly that there was, for a considerable time, much uncertainty in the diagnosis.

Cases like these, in which the disease is so feebly developed that the patient is never seriously sick, though unimportant pathologically, must be recognized in a treatise on cerebro-spinal fever.

Mode of commencement.—Cerebro-spinal fever rarely begins in the forenoon after a night of quiet and sound sleep. In the cases which I observed in the severe and fatal epidemic of 1872, and in the thirty-six cases to be tabulated in the next RECORD, the commencement was almost without exception between mid-day and midnight. The fact that this disease does not commence after the repose of night, till several hours of the day have passed, shows the propriety and need of enjoining a quiet and regular mode of life, free from excitement, and with sufficient hours of sleep, during the time in which the epidemic is prevailing.

The commencement is usually without premonitory stage, and sudden ; unlike, therefore, the beginning of other forms of meningitis, which come on gradually and are preceded by symptoms which, if rightly interpreted, direct attention to the cerebro-spinal system. Exceptionally certain premonitions occur for a few hours or days before the advent of the disease, such as languor, chilliness, etc. Mild cases more frequently begin gradually, and with certain premonitions, than severe cases. The ordinary mode of commencement is as follows : The patient is seized with vomiting, headache, and perhaps a chill or chilliness, so that there is a sudden change from perfect health to a state of serious sickness. Rigor or chilliness is a common initial symptom, especially in adult patients. One patient, an adult female, had three or four chills of considerable severity in the commencement of the attack. Children often have clonic convulsions in place of the chill, or immediately after it, partial or general, slight or severe. Stupor more or less profound, or less frequently delirium succeeds. In the gravest cases semi-coma occurs within the first few hours, in which patients are with difficulty aroused, or profound coma, which, in spite of prompt and appropriate treatment, is speedily fatal. Those thus stricken down by the violent onset of the disease, if aroused to consciousness, complain of severe headache, with or without, or alternating with equally severe neuralgic pains in some part of the trunk, or in one of the extremities. The pain frequently shifts from one part to another. Among the early symptoms of cerebro-spinal fever are those which pertain to the eye. The pupils are dilated, or less frequently contracted, and they respond feebly, or not at all, to light if the attack be severe and dangerous ; often they oscillate, and occasionally one is larger than the other. Vomiting, with little apparent nausea, and often projectile, is common in the commencement of cerebro-spinal fever. It occurred as an early symptom in fifty-one of fifty-six cases observed by Dr. Sanderson. In ninety-seven cases occurring in

New York, most of them observed by myself, but a few of them related to me by the late Dr. John G. Sewall, vomiting occurred as an early symptom in sixty-eight cases. Its absence on the first day was recorded in only three cases, while in the remaining twenty-seven patients the records of the first day make no mention of its presence or absence. It was probably present in most of these twenty-seven cases as one of the first symptoms.

Since the epidemic of 1872, in examining patients now numbering thirty-six, as has been already stated, I have made careful enquiry in regard to the mode of commencement, and with only two or three exceptions the previous health had either been good, or if symptoms of ill-health antedated the cerebro-spinal fever, they were due to some ailment entirely distinct from this disease. In a boy four and a half years of age, living in Broadway, it was stated to me that the cerebro-spinal fever came on gradually, with pains in the head and elsewhere; this case was mild throughout, and the patient was never in imminent danger. In nearly all the cases, if the patients were at home and under observation, the exact moment of the beginning of the disease could be stated. Thus a man aged twenty-eight returned from his work at mid-day, April 23, 1883, in good health and cheerful, ate a hearty meal at 12 M. and at 1 P.M. had a chill, with intense headache and severe vomiting. Minute red points appeared in his face after the vomiting, from capillary extravasations. In this case the interesting fact was observed of a cessation of the symptoms, so that on the 24th and 25th, being free from pain, he went to Brooklyn. On the 26th, however, the symptoms returned. He had pains in the head, back, and extremities, and was seriously sick. Occasional remissions, so that very grave symptoms become mild for a time, and then return in full severity, as well as distinct intermissions as in this case, have been frequently noticed by observers in different epidemics. A little girl, previously entirely well, was slightly punished on June 11, 1882; immediately she vomited, and seemed quite sick; by kind nursing on the part of the mother she became better, so that on the 12th she had some appetite and went out. On the 13th, cerebro-spinal fever began, with a temperature of 103° , and its course was tedious. A robust girl, aged thirteen, vivacious and cheerful, went as usual in the morning to one of the public schools, entirely well. Before the school was dismissed she returned home crying, on account of dizziness and violent pain on the top of her head, in her knees, and calves of the legs. The case was attended by Professors Alonzo Clark, Knapp, and myself, and was fatal after four and a half weeks. A boy, aged ten, returned from another public school in a similar manner, having gone to it in the morning in apparent perfect health.

We may, therefore, summarize as follows the symptoms which commonly attend the commencement of cerebro-spinal fever: violent pain in some part of the head, and sometimes also in the trunk or limbs, vomiting, a chill or chilliness, clonic convulsions, dizziness, dilated, sluggish, or altered pupils, fever of greater or less intensity according to the severity of the attack, heat of head, and in most patients of the surface generally. If the disease be of a severe and dangerous type, these symptoms are apt to be followed within a few hours by delirium, semi-coma, or coma.

SYMPTOMS.

Nervous system.—Since in cerebro-spinal fever extensive and intense inflammation occurs of the cerebral and spinal meninges, with more or less congestion of the brain and spinal cord, lesions, which we will consider hereafter, we would expect that this disease would be attended by severe and dangerous symptoms, inasmuch as the cerebro-spinal axis exerts such a controlling influence upon the functions of the body. Also we would expect that the symptoms would vary according to the portion of the meninges which happens to be most se-

verely inflamed. There is, indeed, variation in symptoms according to the extent and intensity of the meningitis, and the degree in which the cerebro-spinal axis is congested or implicated, but certain symptoms occur in all or nearly all cases, and as they are characteristic they render diagnosis easy.

Pain, already described as an initial symptom, continues during the acute period of the malady. It is ordinarily severe, eliciting moans from the sufferer, but its intensity varies in different patients. Its most frequent seat is the head, and the location of the cephalalgia varies in different patients and in the same patient at different times. One refers it to the top of the head, another to the occiput, and another to the frontal region, and the same patient at different times may complain of all these parts. The pain is described as sharp, lancinating, or boring. It is also common in the neck, especially in the nucha, the epigastrium, umbilical, and lumbar regions, along the spine (rachialgia), and in the extremities, where it shifts from one part to another. It is more common and persistent in the head and along the spine than elsewhere. The patient, if old enough to speak, and not delirious or too stupid, often exclaims, "Oh! my head," from the intensity of his suffering, but after some moments complains equally of pain in some other part, while perhaps the headache has ceased or is milder. In a few instances the headache is absent, or is slight and transient, while the pain is severe elsewhere. After some days the pain begins to abate, and by the close of the second week is much less pronounced than previously. Vertigo occurs with the headache, so that the patient reels in attempting to stand or walk. I have stated above that vertigo may be a prominent initial symptom, as in the girl of thirteen years, who suddenly became sick in the public school where she was attending, and reached her home with difficulty on account of the headache and dizziness. Contributing to the unsteadiness of the muscular movements is a notable loss of flesh and strength, which occurs early and increases.

The state of the patient's mind is interesting. It is well expressed in ordinary cases by the term apathy or indifference, and between this mental state and coma on the one hand, and acute delirium on the other, there is every grade of mental disturbance. Some patients seem totally unconscious of the words or presence of those around them, when it subsequently appears that they understood what was said or done. Delirium is not infrequent, especially in the older children and adults. Its form is various, most frequently quiet or passive, but occasionally maniacal, so that forcible restraint is required. It sometimes resembles intoxication or hysteria, or it may appear as a simple delusion in regard to certain subjects. Thus one of my patients, a boy of five years, appeared for the most part rational, protruding his tongue when requested, and ordinarily answering questions correctly, but he constantly mistook his mother—who was always at his bed-side—for another person. Severe active delirium is commonly preceded by intense headache. In favorable cases the delirium is usually short, but in the unfavorable it is apt to continue with little abatement till coma supervenes.

On account of the pain and the disordered state of the mind, patients seldom remain quiet in bed unless they are comatose, or the disease be mild or so far advanced that muscular movements are difficult from weakness. In severe cases they are ordinarily quiet for a few moments, as if slumbering, and then, aroused by the pain, they roll or toss from one part of the bed to another. One of my patients, a boy of five years, repeatedly made the entire circuit of the bed during the spells of restlessness. In mild cases, or cases attended by less headache or mental disturbance, patients are quiet, usually with their eyes closed, unless when disturbed.

Hyperæsthesia of the surface is another common symptom. Few patients, not comatose, are free from it during the first weeks, and it materially increases the suffer-

ing. Friction upon the surface, and even slight pressure with the fingers upon certain parts extort cries. Gently separating the eyelids for the purpose of inspecting the eyes, and moving the limbs, or changing the position of the head, evidently increase the suffering, and are resisted. I have sometimes heard such expressions of suffering from slowly introducing the thermometer into the rectum that I was led to believe that the anal and perhaps rectal surfaces were hypersensitive. The hyperæsthesia has diagnostic value, for there is no disease with which cerebro-spinal fever is likely to be confounded in which it is so great. It is due to the spinal meningitis, and is appreciable even in a state of semi-coma. The headache and hyperæsthesia fluctuate greatly in the course of the disease, and the former sometimes recurs at times, especially from mental excitement, or from an afflux of blood to the brain from physical exertion, for months after the health is otherwise fully restored.

Some contraction of certain muscles or groups of muscles is present in all typical cases. In a small proportion of patients it is absent or is not a prominent symptom, namely, in those in whom the encephalon is mainly involved, the spinal cord and meninges being but slightly affected or not at all. This contraction is most marked in the muscles of the nucha, causing retraction of the head, but it is also common in the posterior muscles of the trunk, causing opisthotonos, and in less degree in those of the abdomen and lower extremities, and hence the flexed position of the thighs and legs, in which patients obtain most relief. The muscular contraction is not an initial symptom. I have ordinarily first observed it about the close of the second day, but sometimes as early as the close of the first day, and in other instances not till the close of the third day. Attempts to overcome the rigidity, as by bringing forward the head, are very painful, and cause the patient to resist. In young children having a mild form of the fever, with little retraction of the head, the rigidity is sometimes not easily detected. I have been able in such cases to satisfy myself and the friends of its presence, by placing the child in an upright position, as on the lap of the mother, and observing the difficulty with which the head is brought forward on presenting to the patient a tumblerful of cold water, which is craved on account of the thirst. The usual position of the patient in bed, in a typical or marked case, is with the head thrown back, the thighs and legs flexed, with or without forward arching of the spine. The muscular contraction and rigidity continue from three to five weeks, more or less, and abate gradually; occasionally they continue much longer. Through the kindness of Dr. Henry Griswold I was allowed to see an infant of seven months in the tenth week of the disease. It was still very fretful, and exhibited decided prominence of the anterior fontanelle, probably from intra-cranial serous effusion and marked rigidity of the muscles of the nucha, with retraction of the head.

Paralysis is another occasional symptom, but complete paralysis of any muscle or group of muscles is less frequent than one would suppose from the nature of the malady. It may occur early, but is sometimes a late symptom. It may be limited to one or two of the limbs, as the legs, or an arm and a leg, or it may be more general. In a case occurring in Roosevelt Hospital, and published in the *NEW YORK MEDICAL RECORD* for October 10, 1878, the patient, a boy of ten years, was unable to move his legs one hour after the commencement of the disease. This sudden development of paraplegia in the commencement of cerebro-spinal fever resembled that of infantile paralysis, and was probably due to the same cause, to wit, active inflammatory congestion of the anterior cornua of the spinal column. The sudden and complete loss of speech which occurs in certain cases, when consciousness is retained and the vocal organs are in their normal state, seems to be due to the fact that the portion of the brain which controls the function of speech is acutely congested, or is the seat of effusion. Thus, in

June, 1882, a girl of three years, whom I attended, lost her speech on the second day of cerebro-spinal fever, and she was unable to articulate even the simplest word for two and a half months. Finally she began to utter slowly and with difficulty the easiest monosyllables, and now, after a lapse of more than a year, her speech is slow and lisping, while her hands are tremulous and unsteady. She is easily fatigued and cries often from over-sensitiveness. During the long period of speechlessness she daily made efforts to talk, but without uttering a sound. Strabismus, to which we will allude hereafter in treating of the eye, is a common symptom, either transient or protracted, due to paralysis of certain of the motor muscles of the eye.

Paralysis of more or fewer muscles has been noticed and recorded by many observers in this country and in Europe. Dr. Law observed a patient in the epidemic of 1865, in Dublin, who could move neither arms nor legs, and Wunderlich saw one who had paralysis of both lower extremities and a considerable part of the trunk. As this symptom is due to the inflammatory process in the cerebro-spinal axis, it usually disappears in a few weeks as the inflammation abates and absorption of the inflammatory products occurs, but it may be more protracted. In Wunderlich's case there was only partial recovery from the paralysis after the lapse of five months.

Clonic convulsions have already been alluded to among the early symptoms of the attack. They indicate a grave form of the disease, and are not infrequent in young children, in whom they appear to occur in place of the chill which is common in those of a more advanced age. The eclamptic attack may be short and not repeated, or it may be protracted, or return again and again when the medicines which control it are suspended. Under such circumstances it is apt to end in profound coma, and is, of course, a symptom of great gravity. Thus an infant of seven months had unilateral eclamptic attacks daily during the first week of the attack. The mother informed me that the convulsions seldom lasted longer than three minutes, and that the intervals between them were short. The child recovered with loss of sight from the cerebro-spinal fever, but still after the lapse of a year, when I examined him, had symptoms which were apparently due to hydrocephalus. Another infant of eleven months had clonic convulsions nearly constantly during the first twenty-four hours, but with occasional brief intermissions. On the following day he was in profound coma, and apparently dying, with a temperature of 105°. To my astonishment he gradually emerged from the state of unconsciousness, and after a week was able to sit in his cradle long enough to take drinks.

Occasionally eclampsia does not occur in the first days, but in the second or third week, when it is usually accompanied by an increase of other symptoms, due to a recrudescence of the disease. A female infant, aged eleven months, treated by me in 1882, had been sick one week, when, during an increase in the febrile movement, she had one eclamptic seizure. Her recovery though slow was complete. A boy, aged eleven and one-half years, whose attack began with a chill, violent headache, and a febrile movement, and whom I visited frequently, died on the fourth day. Clonic convulsions did not occur in his case until within twenty-four hours of his death, when he had six seizures, which ended in coma.

Though adult patients are much less liable to eclampsia than children, they are not entirely exempt. A male patient, aged twenty-eight years, whom I saw in consultation, had a single clonic convulsion lasting ten to fifteen minutes on the third day of his illness. In five weeks he had fully recovered, except that his headache returned upon any excitement. Even drinking a cup of beer caused it. Clonic convulsions are, however, much less common than tonic muscular contraction and rigidity already alluded to. This occurs to a greater or less extent in nearly all cases, and is a symptom of diagnostic value, the rigidity often extending to the muscles of the

extremities. Thus in a child, aged three years, who had no eclampsia, the tonic contraction of the muscles of the extremities did not relax till after the twelfth day.

Choreic or choreiform movements are occasionally observed. I do not allude to the tremulousness which sometimes occurs from weakness, or as a premonition of eclampsia, but a movement which has the character of true chorea. An infant, aged ten months, began to have choreic movements during the acute stage of the disease, most marked in the upper extremities, and ceasing in sleep. They continued during the remainder of the life of the child, death occurring ten months subsequently of diphtheria. Rarely a choreiform movement of the eyes is also observed, a lateral movement from right to left and left to right. I have seen from recollection two such cases.

Drowsiness, already alluded to, is a common symptom, and it exists in all grades, from slight stupor to profound coma. In some patients it is present from the first hour, while in others it occurs after a period of restlessness or delirium, or it alternates with it. Stupor more or less profound is common after the attack of eclampsia or the chill. That it is a frequent symptom in severe cases receives ready explanation from the state of the brain and its meninges, for the exudation which occurs upon the surface of the brain and the serous effusion within the ventricles are sufficient to cause it, by compressing the cerebral substance. It is surprising in some cases how profound the stupor may be, a state indeed of coma, and yet the patient gradually emerges from it and recovers. In the epidemic of 1872, in New York City, when the malady was new to us, many physicians predicted certain death, and employed remedies without expectation of any benefit, on account of the apparently hopeless state of patients, who seemed to be in profound coma, and yet not a few of them gradually and fully recovered.

Digestive system.—Vomiting, which is the most prominent symptom referable to the digestive system, has already been alluded to. Occurring early in the disease, it may cease in a few hours, or not till after several days, and often it returns during the periods of recrudescence, which are common in the progress of the fever. It occurs with little effort, and without previous nausea, or with little nausea, as is usual when it has a cerebral origin. It does not differ as a symptom from the vomiting which is so common in other forms of meningitis. The substance vomited consists of the ingesta and the secretions, as mucus and bile. Having a similar origin is a sensation of faintness or depression referred to the epigastrium.

The appetite is usually impaired or lost during the active period of the attack, and it is not fully restored till convalescence is well advanced. Occasionally considerable nutriment is taken, and with apparent relish, as by one of my patients, twenty-eight years of age, who always had some appetite. Ordinarily, on account of repeated vomitings, constant febrile movement, impaired appetite and digestion, patients progressively lose flesh and strength, so that in protracted cases emaciation is always a prominent symptom, and is often extreme. Great emaciation and loss of strength, which attend many cases after the lapse of several weeks, greatly diminish the chances of a favorable termination. Thirst, already alluded to, and constipation are common in this as in other forms of meningitis, but retraction of the abdomen is not a notable symptom, except in protracted and greatly wasted cases. The diarrhoea which is occasionally present in cerebro-spinal fever in the summer months must be regarded as a distinct disease and a complication. The tongue, buccal, and faucial surfaces present nothing unusual in their appearance. It is seldom that the sordes and dry and brownish fur occur, which are so common in typhus and typhoid fevers, even in the most protracted and emaciated cases. The tongue is usually moist and but slightly furred.

I have seen in consultation two patients that perished

early with inability to swallow as the prominent symptom, attended in both by an abundant secretion upon the faucial surface, without any redness, swelling, or other evidence of inflammation. The early death of these young children, whose ages were ten months and two years, rendered the diagnosis less certain than in most other patients, but the attending physicians as well as myself diagnosed cerebro-spinal fever with suddenly developed paralysis of the muscles of deglutition, so that no nutriment could be taken. If our understanding of these interesting cases were correct, the paralysis was caused by lesion of that portion of the medulla oblongata which controls the function of deglutition, or else from injury of the intra-cranial portions of the nerves which supply the muscles concerned in this act. The following were the cases alluded to:

O—, male, two years of age, became feverish and dull, but without vomiting, on October 22, 1882; axillary temperature, 102°. On the following day the inability to swallow occurred, and the muscles of deglutition appeared totally inactive. Death occurred on the third day, suddenly, and apparently easily, as if from arrested function of important nerves, especially the pneumogastric. The abundant secretion of thin mucus or transudation of serum covering the faucial surface, and reaccumulating as soon as removed, without any notable change in the appearance of the fauces, was remarkable. The physician in attendance, who for more than thirty years had had a large city practice, had seen no similar case, nor had I at the time.

Soon afterward the second case occurred. An infant of ten months, without cough or embarrassment of respiration, or faucial redness or swelling, lost the power of deglutition soon after the commencement of the supposed cerebro-spinal fever, so that in the attempts to swallow the drinks entered the larynx, and the secretion or exudation was abundant as in the other case. Death occurred in forty-eight hours. The rectal temperature was only 101°.

In another case, ultimately fatal, and in which the diagnosis of cerebro-spinal fever was certain, a robust girl, aged twelve, suddenly lost the power of deglutition at one time during her sickness, although she was entirely conscious and repeatedly endeavored to swallow. The ability to swallow returned in a few days.

(To be continued.)

IMMEDIATE OPERATION FOR LACERATION OF THE PERINEUM.¹

By R. C. M. PAGE, M.D.,

NEW YORK.

It has been, and is now a question, in cases of laceration of the perineum during parturition, whether the immediate or the secondary operation should be performed.

In cases of slight rupture no operation may be absolutely necessary, as the parts may, and frequently do, heal sufficiently to render the perineum nearly as good as it was originally.

In cases of extensive rupture, however, all authors agree that one or the other operation must be performed, since it is the rare exception for such lacerations to heal by first intention when left to themselves. I do not remember ever to have seen one. Lusk, in his work entitled "The Science and Art of Midwifery," page 576 (New York: D. Appleton & Co., 1882), says: "Only a very credulous person really believes that he has witnessed union by first intention in extensive ruptures as the result of tying the knees together and enjoining rest upon the side."

Playfair, of London, recommends the immediate operation, even in the severer forms of rupture extending back to, or even through, the sphincter ani. He also recommends the immediate operation in slight cases, in

¹ Read before the Northwestern Medical and Surgical Society, November 21, 1883.

order to make sure of union by first intention, and for this purpose he uses one or two interrupted sutures of silver wire or carbolized catgut at once. Edis, of London, is of the opinion that where the sphincter ani, or recto-vaginal septum, is not seriously involved so as to make the operation a serious or lengthy one, the immediate operation should be performed; but that the laceration may be so extensive, or from special causes the primary operation may not be deemed expedient, and the secondary operation will then have to be performed later on.

Lusk (*op. cit.*, page 576) says: "To the immediate operation there can be no valid objection. It is not difficult, it is not extremely painful, and its performance, as a rule, diminishes the risks of infection and shortens the puerperal period. In private practice failure is the exception."

Hospital statistics regarding the immediate operation for lacerated perineum appear to be for the most part wanting. From inquiries made, however, at the various lying-in hospitals in this city, I learned that it was always performed when necessary, and that the result has been usually successful. Dr. H. Frankenburg, of Bellevue Hospital, reports 18 cases recorded at the Emergency Hospital; of these, 11 were cured and 7 were failures. Dr. Kate Parker, of the Infant Asylum, reports 4 cases as recorded at that institution; of these 2 were cured and 2 failed. Dr. C. Remsen, of the Nursery and Child's Hospital, reports 2 cases, both cured, and Dr. Stanton Allen, of the Lying-in Asylum, 85 Marion Street, reports 1 case; it was operated on a short time ago by the attending physician, Dr. Henry D. Nicoll, and union was perfect.

Of a total number of 25 recorded hospital cases, therefore, 16 were cured and 9 were failures.

These few statistics are insufficient to warrant any decision on the subject, but they go to show that even in hospital practice the immediate operation is frequently successful; more so now, perhaps, than it was eight or ten years ago. Dr. W. R. Gillette, in the "Report of the Lying-in Service of the New York Charity Hospital, 1875," states under head of Forceps Deliveries: "The perineum was lacerated to the second degree in two cases. The rents were sewed up in each case by silver wire, but with generally unsatisfactory results. It is the practice of our service to sew up all rents of the perineum immediately upon their occurrence. The results are hardly such as to encourage us in the continuance of the practice, for we never get complete union when the perineum is entirely torn through. In rents of the second degree we occasionally succeed. The superficial rents of the perineum seem to unite just as well when we treat them by the postural method of tying the legs together." The results in cases of the secondary operation, as recorded at the Woman's Hospital in this city, are, I believe, much more favorable than those obtained by the immediate operation in the various charitable lying-in hospitals. It must be remembered, however, that patients at the Woman's Hospital are usually from the better classes, and have surroundings and conveniences equal, if not superior, to those that can be obtained at any hotel or private residence. They should, therefore, be properly classified among those in private practice.

The total number of cases of lacerated perineum admitted to the Woman's Hospital since its opening in April, 1855, up to September 15th of the present year, is 809, of which 26 were not treated or the result was not stated. Of the remaining 783 cases in which the secondary operation was performed, 364 have been recorded as "laceration of the perineum and cervix uteri." They must, therefore, be omitted, since of those reported improved it is not stated whether the perineum or cervix uteri is meant. Of the remaining 419 cases, 313 were cured, 83 were improved, 21 were not improved, and there were two deaths—one from rapid septicemia, with metastatic parotitis following the operation, and one from a supervening attack of pneumonia.

Whatever be the result in hospitals, failure of the immediate operation in private practice is the rare exception. Of a collection of 100 cases, including all degrees of rupture, 90 were cured, 9 improved, and 1 was not improved. The latter was due to hemorrhage from the wound. In the 9 improved cases union was incomplete, and in each case a small fistulous opening into the vagina remained. This was doubtless due to the cutting out of sutures.

So far as regards these two operations, therefore, I believe that, other things being equal, the immediate operation in private practice, at least, is as uniformly successful as the secondary. This being true, there are numerous evident reasons why the immediate operation should be performed. It can but fail, and in that case the secondary operation can be performed afterward.

In slight cases there is no necessity for anesthetics, but where the laceration is extensive they may be required. The wound should be thoroughly cleansed with a three per cent. carbolic or other antiseptic lotion before closing it, and, as an additional precaution, a sponge wrung out of the same material may be placed against the os uteri during the operation. In cases of extensive rupture, extending into the rectum and high up in the vagina, these parts may be closed first with carbolized catgut sutures, after Simon's method. The rest should then be closed by means of the interrupted suture. Giving opium for the purpose of constipating the bowels is bad practice. If the patient can pass her urine let her do so; it does not in the least interfere with the operation, and the use of the catheter is not only inconvenient to all parties, but almost certain to cause cystitis. During the after-treatment the vagina should be carefully syringed out about twice daily with a tepid three per cent. carbolic or other antiseptic lotion.

The sutures should be made to embrace an abundance of tissue—half an inch or more on each side of the line of rupture—otherwise they do not bring the parts together properly, and are likely to cut out. They should be removed on the seventh or eighth day, and not before. Want of attention to these points, as well as to antiseptic precautions and a lack of proper care and intelligence during the after-treatment, are the chief causes of failure in this, as in the secondary operation. In my opinion, atmospheric conditions have but little influence on the result.

In regard to the kind of suture used, I have had little experience with any but the ordinary interrupted suture, such as is generally used at present. I do not think that there is any particular advantage in the *serres fines* of Vidal, as recommended by Mann and Garrigues, even in slight cases; and the quill suture is both clumsy and untrustworthy, inasmuch as it does not go entirely around the wound.

Regarding materials for sutures, there are only three that I shall consider necessary to mention in connection with this operation. They are silver wire, silk, and catgut.

In operations for vesico-vaginal fistula and the like, it is often difficult, if not sometimes impossible, to tie a suture with the proper degree of tension in so confined a space. In such operations silver wire has no substitute worthy of mention. The degree of tension can be perfectly regulated by simply twisting or untwisting the wire, whereas, if silk or catgut be used, the knot when once tied has to remain so, or else a new suture must be introduced. It was for such cases that silver was originally intended by its great inventor, as every one knows, but in time it came into general use, as being more aseptic than silk and less liable to cut the tissues. This was undoubtedly true. With the present methods of rendering silk aseptic, however, I believe that for general use, as in perineal operations, it is equal in these respects to silver wire, besides possessing the additional advantage of giving the patient no inconvenience while *in situ*, does not interfere with cleansing the parts, and causes no pain

in removing it. Catgut had the objection to it of being too quickly absorbed. Kocher, of Berne, however, appears to have overcome this difficulty by placing it in oil of juniper for twenty-four hours, and then in alcohol (ninety-five per cent. strength) for preservation. At the time of immediate use it may be dipped in a five per cent. solution of carbolic acid. (Pilcher, "Treatment of Wounds," p. 112. New York: W. Wood & Co. 1883).

When the immediate operation has not been performed, or has failed, the secondary operation should not be deferred any longer than is necessary to get the patient in proper condition—two months or so from the date of delivery. For this purpose tonics should be given, if necessary, and the general health attended to.

31 WEST THIRTY-THIRD STREET.
November 24, 1883.

ON THE USE OF PEPTONES IN DISEASE.

By J. W. FRANKL, M.D.,

(NEW YORK.)

WHEN the immortal Stokes requested that his epitaph should symbolize the lesson of his life in the memorable words, "He fed fevers," he pointed out clearly and unmistakably the direction that the therapeusis of the future should take.

Gradually our faith in specifics has been rudely shaken; slowly pathology has demonstrated that disease is, in many instances, self-limited, and must run a definite course. But while we may have lost that confiding faith in some of our remedies, this very fact has directed more decided attention to those conditions, in health and in disease, which tend toward the conservation of the vital forces.

The physiology of digestion has naturally received marked and distinguished attention, and although the process of digestion with all its inherent difficulties still, and probably always will present unexplained phenomena, the progress of the past score of years has added mightily to our former crude notions. From the simple idea that albuminous substances were all alike, their number has multiplied, each presenting attributes sufficiently marked to make them separately recognizable, and similarly, in contrast to the former opinion, that this one albumen when changed into albuminose, as it was formerly called, constituted the great assimilable albuminoid body, we now know many which, under the generic title of peptones, constitute quite a group of absorbable substances.

It is well established that the gastric, the pancreatic, and intestinal juices, each in succession from above downward, act upon the food (the function of the bile we will not here consider). Each in turn has an action which results in the conversion of albuminous compounds into different peptones—the latter juices giving rise to the simultaneous production of certain products of decomposition (skatol, indol, tyrosin, leucin, etc.). At one time it was thought that the peptones were themselves products of decomposition, but this view has been proven erroneous, and still further, it has fully been shown by Poehl, Henniger, and others, that they are easily reconvertible into albumen.

The convincing and excellent monograph of Dr. Poehl, of St. Petersburg (quoted in an editorial of THE MEDICAL RECORD of July 21, 1883, p. 72), helped to establish the fact that the peptonization of albumen is a hydration simply, and not a product of decomposition. Further, that peptone can be reconverted readily into albumen, and that chemical analysis reveals no characteristic difference between albumen and peptone, and that the optical properties of the two bodies are also entirely alike. This latter Poehl correctly thinks could not be true if the two bodies possessed any real chemical difference.

Acting upon the proposition that peptone is a modification, not a decomposition product of albumen, Ploss

and Gyergyoi, some ten years ago, and subsequently Maly, Adam Kiewiez, and others, undertook a series of experiments upon animals, and later upon man, by substituting peptone for albumen in their food. Their anticipated results were fully realized by seeing the subjects of these experiments not only remain alive but very markedly gain in weight. It was these investigations which furnished the basis for the use of peptonized foods in practice. In Germany they soon established a place for themselves, later in England, and later still in the United States. But in this, as in all matters of progressive scientific thought, the great body of the profession fail to realize their importance. There has ever been an antagonism, though unspoken, between the demonstrable facts of the physiologist and pathologist and the application of remedies based upon these by the practicing physician. Accustomed to the use of beef-teas and meat extracts, he clings to them with unwarrantable tenacity.

No one better understood the shortcomings of beef extracts as an article of nutrition than did Liebig himself. In *The Lancet* of November 11, 1865, he himself admits how much more preferable would be a preparation of meat containing its albuminous portion, instead of beef extracts, if only it could be brought within the means of our patients. The force of these remarks is still better appreciated when we consider, first, that the albuminous constituents of meat coagulate at a temperature far below the boiling-point of water, and that soups and broths therefore must necessarily contain but little albumen. They contain only the extractive matters—namely, the flavoring constituents, some of the organic and some of the inorganic salts, and a small percentage of gelatine. As nutritive substances these must manifestly be inadequate. Cold infusions of meat, especially with an addition of diluted muriatic acid, give better results as to the percentage of albumen, but even this does not contain, according to Voit,¹ more than 1.15 per cent. of albumen, so that six ounces do not contain more than half a drachm of albumen.

That such preparations have a value as stimulants, as tonics and appetizers in those suffering from debilitated stomachs, cannot be questioned. But the problem that we must still seek to solve is, cannot we maintain the general nutrition at a higher standard, and prevent the marked loss of tissue in prolonged febrile movements and in other conditions in which digestion is prevented? If the tissues require albumen in health, surely the same requisite exists in diseased states. But if the digestion is so at fault, as is the case, that the administration of ordinary albuminous food is out of the question, then is it not possible to peptonize the albumen as to make it sufficiently assimilable in these conditions? To peptonize by the use of pancreatic emulsions appears to us to permit the possibility and probability of inaugurating, coincidentally with peptonization, some of the decomposition already spoken of which takes place in the intestine as one of the actions of pancreatic juice. Peptones, for this reason, seem eminently more desirable for this purpose. *Still further, is it not reversing the order of digestion to begin in the stomach with pancreatic digestion?*

Seeking to place my theoretical deductions upon the basis of practical application, I began the use of one of the preparations of peptonized beef, using for this purpose "Rudisch's" preparation of the "sarco"-peptones.

The careful analysis of Dr. Endemann, of this city, informed me that it contained over thirty-six per cent. of peptones. Further, it was not objectionable in its flavor. My experience has enabled me to collate the following facts, and I am much pleased to state that the results have in many instances exceeded my most sanguine expectations. First, as to the age at which sarco-peptones are admissible: I have used them for four weeks in an infant eighteen months old. Children bear them equally

¹ Herrmann: See *Handbuch der Physiologie*, vol. vi., part 1., p. 448.

well with adults. Secondly, as to the diseases in which they have been used. Among many cases in which they have been faithfully tried, I refer to the following, not as specially selected, but simply as typical cases: In three cases of typhoid fever; in one the patient was fed exclusively on sarco-peptones for two weeks, and in two cases for six weeks; in two cases of chronic pneumonia, in both cases for four weeks; in one case of acute pneumonia, for eight days exclusively, milk being vomited; in one case of fracture in an aged person, for a week exclusively; in one case of icterus catarrhalis; in two cases of rheumatism, one complicated with Bright's disease, in one used exclusively for four weeks; in four cases of vomiting—one of pregnancy, one of anæmia after parturition, one of gastric catarrh after diphtheria, and one of cancer of the stomach, it was used with excellent results; in one case of pelvic peritonitis it was well borne; in one case of post-partum hemorrhage; also in a case of diabetes and gangrene.

The above cases sufficiently well illustrate, first, that the sarco-peptones are borne by the stomach when milk is not retained; secondly, that their nutritive value is beyond that of milk, judging from the better condition of my patients, and of beef broths; thirdly, from its readily assimilable form, even infants can be nourished by it, when milk is rejected. I have caused diligent inquiry to be made among my friends and acquaintances in the profession as to their success in the use of the sarco-peptones. The replies were uniform with my experience. I feel certain, however, that I cannot do more wisely than to quote from a letter from one whose dictum always receives the attention and marked consideration which, coming as it does from such eminent authority, it certainly deserves. Dr. A. Jacobi says: "I commenced the use of peptonized beef a very short time after Leube taught the preparation and indications of his 'meat solution.' For many years I employed it, both by mouth and by rectum; by mouth, either undiluted, by the teaspoonful or dessertspoonful, or diluted in beef broth, or with tomato sauce, etc.; in the rectum, diluted with warm water in different proportions. There are some facts which need not be proven, but which merely require application. Such a fact appears to me the great usefulness of a substance which has already been peptonized, *i. e.*, digested, over one whose claims on the functions of the stomach begin as soon as they enter the stomach. Thus, without going into specifications, I remember a few cases of cancer of the pylorus, in which the violent vomiting stopped entirely for some time, and immediately, when nothing but Leube's solution was introduced. These cases occurred even at a time when there was but a single place in New York City where the 'meat solution' was for sale, and when the preparation, in regard to uniformity and reliability, left much to be desired sometimes. This latter circumstance has often deterred me from using it when I might have derived great benefit from its use, but the sad fact will always remain, that the main necessities of the human species in regard to food and medicines are not also the main objects of the individual manufacturer and tradesman.

"I have also used it in cases of thorough hydræmia, slow convalescence, and all those conditions in which the stomach does not prepare its own solvent and digesting fluids. Wherever there is a mucous membrane and lymphatics, a genuine peptone ought to be, and is absorbed. Atrophy of the glands of the stomach, with its absolute apepsia, is one of the best indications for its use. A certain degree of gastric catarrh does not form a contra-indication, least of all, intestinal catarrh.

"Here I desire to direct your attention to the difference in the effects of peptones and 'beef-tea.' In cases of intestinal catarrh with diarrhoea, the latter—so frequently resorted to in general practice—is apt to be injurious by the concentration of salts in it, perhaps also for some other reason; peptone, however, is not only easily tolerated, but is beneficial, for the reason that it

is absorbed before it reaches the diseased surface. On the condition of the latter when in contact with peptone or anything else everything depends. An inflamed mucous membrane does not absorb, and therefore to administer peptones in a serious form of gastritis, or to inject it into an inflamed rectum, is worse than letting them alone.

"I believe it took years after Professor Lenbe's publications before the manufacturing interest became aware that there was 'money' in the preparation of peptones. The meat solution has a very strong aromatic taste and flavor. It is true that some patients take it well and long, but some object to both those properties from the beginning, or get tired of the preparation very soon. These objections have been the reason for many attempts at producing other preparations of similar nature.

"I have no doubt there are a great many good and reliable ones among them, and the fickleness of the individual taste must often direct the selection of the required article by the physician. I, for my part, have for a long time preferred Rudisch's preparations, particularly his 'Sarco-Peptones.' I have been told that you have experimented a great deal with the same. My reason for preferring it has been, the absolute uniformity and equality of the specimens, and the fact that patients, as a rule, have been willing to take it for a long period in succession. I give it unmixed in teaspoonful or half-teaspoonful doses every half-hour, hour, or two hours, or dilute it with broth, or spread it on stale bread or toast, or mix it with water for rectal injections. For months I have used no other preparation, being satisfied with having at least one which was reliable. I do not mean to say that there are not just as good and palatable ones besides, but I am guided in my selection of that preparation simply by the fact that I have done well with it and cannot expect to do better. I have acted on the same principle which teaches me to demand in many of my prescriptions the drugs of Squibb, knowing that those articles are pure, uniform, and reliable, without meaning to say that his competitors could not furnish the required article just as pure, uniform, and reliable.

"Taking it for granted that you desired to hear from me neither reports of cases nor elaborate communications, I submit to you, dear doctor, the above remarks, brief and fragmentary though they may be, as the general result of my personal observations and experience.

"I know that many of my cases of hydræmia, slow convalescence, chronic disease of the stomach, many cases of gastric dyspepsia, inanition brought about by rachitis and scrofula, and infectious fevers, have been greatly benefited, to say the least, by peptone. Very respectfully yours, A. JACOBI."

CAN INSANITY BE PHILOSOPHICALLY DEFINED?

By J. LEONARD CORNING, M.D.,

NEW YORK.

BEFORE proceeding to the specific discussion of the subject of this enquiry, let us first ask *what is a definition?* "The simplest and most correct notion of a definition is," according to John Stuart Mill, "*a proposition declaratory of the meaning of a word.*" And in concluding his chapter on "Definition," this able writer further says: "In giving a distinct connotation to the general name, the philosopher will endeavor to fix upon such attributes as, while they are common to all the things usually denoted by the name, are also of greatest importance in themselves, either directly, or from the number, the conspicuousness, or the interesting character, of the consequence to which they lead."

In order to select such attributes as are common to all the things denoted by a name, it is first necessary to have an accurate register of all such things.

Now, in reviewing the various definitions which have been proposed for insanity, there is evident one defect

common to them all: They include only such attributes as the formulator of the definition in question considered rightfully belonged to the "disorder." The result of all this has been that there is not to-day a single solitary definition of that which, by some, is considered a disease but which in reality is a *complex of psychical manifestations* traceable to a variety of causes, all of which, to be sure, *result* in interference with the normal functions of the brain. But not only have the definitions themselves been formed by those whose conceptions of mental impairment have been more or less subjective and narrow, but the criticisms of such definitions have been pronounced from a standpoint not one whit more objective. Thus we read that Mr. A. objects to the definition of insanity promulgated by Mr. B., because it would include the abnormal mental manifestations of "alcoholism," or those occurring as the result of cerebral hemorrhage. Or, again we learn that the definition of Mr. C. is incorrect because it would include the mental condition of a man who has received a blow upon the head with a club. And yet such cases are surely not instances of mental sanity!

There was a time when the term insanity—meaning an unsound mind—was applied to only such as exhibited the symptoms of raving mania; and the definitions of the day, if there were any, must have been in accordance with that conception. Since then the range of phenomena included in the term has progressively increased, notably of late years. Consequently the definitions appearing from time to time during the last hundred years have represented in the main connotations of the forms of mental derangement *known at the time*. Whenever, therefore, these *soi disant* experts were asked to give an opinion respecting the mental health of an individual, they calmly ransacked such "forms" of insanity as their often obtuse perspicuity had served to register; and even though there might be *bona fide* evidences of mental unsoundness, refused to recognize it unless the same were found to correspond with some previously recorded "form" of mental aberration.

Imagine this method of procedure applied to the investigation of bodily ailments. What should we think of the clinician who, finding an individual utterly prostrated by disease, should yet refuse to recognize him as ill, simply because he was unable to identify his sickness with any form of malady previously met with by himself, or recorded in the books of others!

But if all the *forms* of mental derangement are not yet described, how are we to enumerate their common attributes in one comprehensive definition? In order to answer this question a simple retrospective glance at the evolution of mental science is all that is necessary. If all the various forms of insanity which have ever been described are placed side by side, and if we seek for one paramount attribute which is characteristic of each and every one of them, it will be found to consist in this: That they are all psychic manifestations of direct or indirect impairment of brain-function. And if it is desired to be still more explicit we can say that: *Insanity is the psychic manifestation of impaired brain-function*, consequent upon causes resident in the brain, or upon extraneous causes acting upon it (the brain). This definition will be seen to include not only all "forms" of mental disease already recognized; but also those forms of mental impairment, which, owing to flagrant inconsistency, as I believe, are not generally recognized as insanity. Of this, however, more hereafter.

Beside the known forms of insanity, this definition also includes all forms that ever can be recognized, provided it be conceded that the brain is the seat of mind. It is evident that this definition includes the case of the man who has received a blow upon the head, causing confusion of ideas or unconsciousness. Moreover, it also includes the case of a man insensible from the effects of cerebral hemorrhage. But such persons are certainly sufferers from mental ill-health; they are not

mentally sane, therefore they must be insane. An intermediate stage is philosophically unthinkable. Moreover, a term designed to connote morbid mental manifestations, should include more than one or several kinds of such manifestation. What, for example, would be thought of the clinician who should declare that a person with gastritis was unsound, whereas another suffering from pneumonia should be pronounced sound (or perchance neither well nor unwell!).

The pathology of corporeal disease is co-extensive with the limits of the entire body; the pathology of mind is as broad as the mind itself. Consequently any generic appellation designed to express bodily unsoundness should include within its scope *all* manifestations of bodily ill-health; consequently, also, any generic name designed to express mental unsoundness should include *all* manifestations of mental ill-health.

Scientifically, therefore, there is no "border line" between health and sickness; between mental sanity and mental insanity. An individual must be healthy or unhealthy; sane or insane. There is no "border land," except such a one as can be produced by an argument which, followed to its legitimate sequences, can only end in the most complete *reductio ad absurdum*. A subject cannot sit astride of the "border line," with one leg dangling in sanity and the other in insanity.

If, however, alienists, both practical and theoretical, still persist in calling certain groups of morbid mental phenomena insanity, and with equal persistency denominate other equally morbid phenomena *not insanity* (nor sanity!), how can a philosophical definition of mental impairment—of insanity—ever be anticipated?

The time has surely arrived to discard such absurd inconsistency, whether the same be the outgrowth of medico-legal, professional, or popular short-sightedness.

Legislation must indeed decide, even where the definition of insanity is strictly scientific, as to the degree of mental illness which renders an individual irresponsible *before the law*. But it does that now, in spite of the many clumsy and purely subjective efforts to designate *only certain* groups of mental disorder as insanity.

Things certainly cannot be worse than they are at present, and a broader and more scientific conception and definition of insanity is certainly a consummation "most devoutly to be wished."

THE THERAPEUTICS OF TYPHOID FEVER.

By VARIOUS AUTHORITIES.

TEMPERATURE.

AUSTIN FLINT.—1. By the employment of cold water externally in cases of typhoid fever, the temperature of the body may, after a variable time of the continuance of the employment, be reduced to 102° or lower.

2. After a period varying very much in different cases, and, also, at different times in the same case, the temperature, as a rule, again rises as high as, or higher than, before the reduction.

3. Repeating the employment of cold as often as the axillary temperature exceeds 103°, the number of repetitions required in different cases is extremely variable.

4. The sponge-bath and the wet sheet with sprinkling may be employed to the exclusion of the bath-tub in the antipyretic treatment in cases of typhoid fever, as well as of other febrile diseases.

5. These modes of employing cold water may be continued sufficiently long for the reduction of temperature to 101° or lower, and repeated as often as may be required, without risk of any immediate injury, and the study of these cases furnishes no ground for supposing that a liability to complications or accidents is thereby increased.

6. Reductions of temperature by these modes as often as it rises, in the axilla, above 103°, improves the condition of the patient. The cases he has studied do not

afford proof either that the fatality of typhoid fever or that its duration is thereby diminished. The study of these cases, however, renders it impossible that this proof would be afforded by a larger collection of cases.

7. The results of the analysis of these cases, although not sustaining the statements of Liebermeister and others respecting the controlling influence of the employment of cold externally in cases of typhoid fever, yet not only show this method of antipyretic treatment to be safe, but afford encouragement to employ it with the expectation of diminishing the severity of the disease and its danger to life.

ALFRED STILLÉ.—It was formerly the practice—for years at least—to bleed and purge; but the exhaustion produced more than outweighed the advantage of the reduction of temperature. Experience has shown that mild diaphoretics, such as effervescing and neutral mixtures, sweet spirit of nitre, aromatic spirit of ammonia, and muriatic acid, are preferable to active cathartics. Another mode of treating the fever now fashionable is by cold water. This method has been adopted on the supposition that temperature is the sole evil. The method consists in immersing the body in water (68° F.) for five to fifteen minutes (according to the age and strength of patient), then wrapping him in dry blankets and giving a glass of wine. He is allowed to remain in the blankets some time. The bath is to be repeated when the temperature rises, say to 102°. In active cases in adults the baths are repeated at intervals of two hours. Persistent repetition is the essential part of the treatment. Cases are recorded in which two hundred such baths have been given. Ordinary cases require thirty or forty. It is claimed that all the typhoid symptoms are abated and the mortality reduced. If this were so, the method would become popular; but the fact remains that baths are not now favored outside of Germany, and by no means generally there. The high temperature is considered the evil, while in reality it is only a symptom of the disease, and never rises so high as, of itself, to necessitate active cold baths. The value of cold baths lies not in the reduction of temperature, but in the diaphoresis which they produce, eliminating the poison. The cold bath, with quinia and digitalis, has been said to reduce the mortality from twenty-seven per cent. to eighty per cent. But this boasted result shows only the advantage of this treatment over the old heroic treatment of venesection and purgation. It makes but a poor showing beside the result of the supporting treatment with no drugs whatever, the mortality of which in London, Paris, and this country is less than five per cent. The treatment by cold water, quinia, and digitalis has been abandoned in the Vienna hospitals, where its mortality was nineteen per cent. to twenty-five per cent. Liebermeister announced that by it the proportion of relapses and the mortality are increased. Others attribute to cold water the increase of hemorrhage, neuralgia, and pain in the limbs. But Liebermeister now admits that the nervous and all other symptoms are relieved, and ulcers prevented, by cold water. The treatment by cold water is probably of value when employed persistently. The method of using quinia is to give fifteen to forty-five grains in the evening, and its effect then is to reduce the temperature and keep it down for twenty-four to forty-eight hours. It is to be repeated when the fever rises. It will be seen that the direct antipyretic effect of quinia is greater than that of cold water. Binz holds the theory that quinia reduces temperature by weakening the power of the zymotic poison. He does not deny that quinia may kill by paralyzing the heart. Peacock, of London, and Niemeyer have both given up the use of large doses of quinia. Quinia in large doses is unnecessary, useless, and often dangerous. Sodium salicylate reduces temperature, but does not improve the typhoid state.

WILLIAM PEPPER.—Temperature is to be kept down by preventive measures rather than by the cold bath,

which is regarded as a *dernier ressort*. When temperature runs up in spite of drugs, the whole body is sponged every two hours—the sponges being squeezed out of a mixture of water and bay rum at a temperature of from 60° to 80°. If the patient's temperature still runs up he is wrapped in sheets wrung out of cold water. The only case in which the cold bath is used is in the first ten days, where the temperature rises above 103° and is not to be controlled by milder measures.

ALONZO CLARK.—When the temperature of the body runs very high, quinia is given in decided doses, or cold water is employed. In young persons the cold bath is the most convenient and efficient means of reducing temperature. The temperature of the bath used is just 10° below the temperature of the patient's body. The patient is allowed to remain in the bath for twenty minutes. If the temperature rises again, another bath is given.

ALFRED L. LOOMIS does not believe in the efficacy of cold baths or of large doses of quinia in arresting the development of typhoid fever. He maintains the temperature of the room in which the patient lies below 60° F. Frequent sponging of the body with cold water has been of service in his hands. As soon as the axillary temperature in the evening rises above 103° F. he places his patients in a bath of a temperature of from 70° to 80° F., and then gradually lowers that temperature until the patient's temperature begins to fall. When the patient's temperature reaches 103° he is to be taken out and put to bed. When his patients are too weak to be put in the bath he employs the wet pack. He regards cold baths as contraindicated by feebleness of the heart's action.

As an antipyretic he gives gr. xxx. of quinia in one dose, or gr. x. every half hour until gr. xxx. or xl. have been administered. He is in the habit of administering an antipyretic dose of quinia when the temperature has been reduced by the baths.

BELLEVUE HOSPITAL.—The treatment at present in vogue is that of quinine and baths. This was begun four or five years ago, and has received such favor that it is quite the routine now. The quinine is given differently. Perhaps the most popular way has been ten grains two or three times a day, the evening dose being doubled if the temperature rises above a particular height, say 105°. It sometimes causes gastric irritation, being given in powder form. If it is vomited pills are tried, and finally double doses by rectum. Quinia was used for a short time, and it reduced temperature like quinine, but irritated the stomach more. Baths in every shape are used, but the sponge-bath is the form most adopted. The patient's temperature is taken; if found above a certain height, he is stripped either entirely naked or perhaps only the upper half of the body. He is then sponged over with water at a temperature of from 60° to 80°. If only half the body is uncovered at a time, that part is allowed to dry, and it is then covered, and the rest of the surface sponged. This process is kept up for fifteen minutes. If that is insufficient to reduce the temperature, it is prolonged to half an hour. It is repeated every one, two, or three hours, according to the result obtained. At the end of the bath a little whiskey is generally given.

The effect of the quinine on the temperature is to reduce it slightly in a considerable number of cases. Its effect on the patient is to produce nausea and vomiting in a small number of cases.

The sponge-baths are almost always pleasant to the patient, if not too frequently repeated. If given every hour, or two hours even, they seem to weary and annoy him. They certainly reduce the temperature in most of the cases. In a small number of these the reduction seems to last for many hours. Sometimes two or three baths given in the afternoon and evening reduce the fever two or three degrees, and it keeps down for twelve hours. But it is not very rare that the baths are given every hour even, without producing very marked effect. The

sponge-bath is a much more efficient antipyretic than quinine. The wet pack is hardly used now. In one case where it was employed pneumonia complicated the disease. The plan of placing the patient in water at a temperature of 98°, and then gradually lowering it, has been tried a number of times, and so far no deaths can be traced to it. But these gradually cooled baths are uniformly annoying and depressing to the patients. They don't like them. Neither have they been proved to reduce temperature permanently any better than the sponge-baths do.

Several cases have been treated upon the Kibbee bed. Its action and effectiveness were similar to immersion in the bath-tub. It did not eliminate the fever from the disease.

The results of the treatment of typhoid fever patients at Bellevue Hospital within the past ten years have shown that large doses of quinia and that the antipyretic treatment by cold baths are unnecessary, and that the employment of mineral acids and of symptomatic remedies is sufficient.

STIMULANTS.

ALFRED STILLÉ.—When the skin is dusky, tongue dry and dark, and patient delirious, use superficial blisters to back of neck, sinapisms on the limbs and over the heart, mustard foot-baths, friction of chest and limbs with stimulating lotions containing turpentine or ammonia. Coffee is better than alcohol. Wine-whey, eggs, egg-nog. Beef essence. Cracker soup. Arrowroot. Alcoholics are not so early or so long needed nor in such quantities as in typhus. Hold alcohol in reserve for use when all else fails. Comparatively few cases require it. Oil of turpentine acts as a cardiac, vascular, and nervous stimulant, and is to be given when there is tympanites. It probably acts also locally on the ulcers. Give five to fifteen drops in emulsion or capsules every three or four hours. It accompanies the blood to all parts of the system and stimulates the capillaries to expel their stagnant contents; it also stimulates the respiratory mucous membrane, causing expulsion of mucus. With the exception of this last action, alcohol answers the same purpose as a stimulant. Hence, in mere prostration, give alcohol; if lung symptoms require treatment, prefer oil of turpentine.

ALFRED L. LOOMIS lays down the following rules with regard to the use of stimulants:

1. They are never to be administered indiscriminately—that is, they are never to be given simply because a patient has typhoid fever.

2. When there is a reasonable doubt as to the propriety of giving or withholding stimulants, it is safer to withhold them, at least until the signs which indicate their use become more marked.

3. In giving stimulants the effects of the first few doses are to be very carefully watched.

4. Stimulants are contraindicated by dry tongue, restlessness, increasing delirium, pulse, and temperature.

BELLEVUE HOSPITAL.—In the latter weeks of the disease in all cases, and during its whole course in many asthenic patients, an important indication is to sustain the heart-power. This is done by a free use of alcohol, whiskey being the form most used at present. The quantity is determined by the needs of the case, but where there is necessity it is not spared, one case being allowed twenty ounces daily for three days with good result. Some use ammonia as well as whiskey, but its action is considered less certain. When it is used the liq. ammon. acet. and the spts. ammon. aromat. are combined. Other symptoms are met by appropriate measures as they arise.

WILLIAM PEPPER.—Stimulants are not administered to patients under the age of puberty, as a general thing. They are only thought to be demanded by some one or more of the following indications, viz.: (1.) Ataxic nervous disturbances. (2.) Profound asthenia. (3.) Circulat-

ory disturbances. (4.) Dry and brown tongue with sordes. The milder forms of stimulus, such as wine-whey, are always used at first. When demanded, whiskey is given with lime-water—the latter being added to prevent coagulation—in the proportion of f ̄ ss. each of whiskey and lime-water to every f ̄ iij. of milk.

ALONZO CLARK.—Two-thirds of his patients have been found to do better without stimulants than with them. A good general rule is the following: *When alcoholics diminish the frequency and increase the force of the pulse, they do good.* In such cases they are given in a quantity sufficient to increase the force of the pulse, and to diminish the restlessness and suffering of the patient.

NERVOUS SYMPTOMS.

ALFRED LOOMIS.—*Headache.*—Warm fomentations are applied to the forehead. Among the anodynes the best for the treatment of this symptom are the bromides and chloral.

Delirium is generally relieved by chloral and opium. In some cases the best results follow the use of stimulants.

ALFRED STILLÉ.—There are two modes of expression of nervous symptoms—the ataxic and the adynamic. The ataxic condition lasts all through the course and denotes an active struggle. Delirium and subsultus belong to the ataxic. They are less dangerous than coma and exhaustion, which belong to the adynamic, and indicate that the typhoid poison has overcome nature. In dynamic the capillaries alternately contract, excluding the poison, and dilate, admitting it; while in adynamic they are continually dilated, admitting it. When the symptoms are ataxic, relieve them by superficial blisters to the nape of the neck, warm pediluvia, cold to the head, and heart stimulants. Give two grains of quinia every two hours as a stimulant. Wine of opium, the equivalent of one grain, as a stimulant to the system, and as adynamia comes on, supplement these by alcohol as a heart stimulant. Do not be over-hasty in giving quinia and alcohol.

ALONZO CLARK.—*Cough*, when it is the result of a catarrh, is treated either by the comp. tr. of benzoin, in ten-drop doses every three or four hours, or by means of the following combination:

R. Mist. guaici f ̄ j.—f ̄ ss.

Tr. balsam. tolu. gtt. vj.—x.

M. Sig.—Every two to four hours.

Occasionally, good has been accomplished by the inhalation of the vapor of warm water for an hour or two every day.

Restlessness is soothed by sponging the surface of the body with warm or cold water. In some cases a Dover's powder is required.

DA COSTA gives a one-grain suppository of opium three times a day. It quiets the bowels if there is any tendency to diarrhoea, and has a good influence over the disturbed action of the nerves. When the opium does not act speedily by the bowels, he gives one-sixth of a grain hypodermically. He finds a combination of digitalis and opium a good one—best suited to cases where there is also rapidity of the heart's action. To calm the nervous system the bromides are given in twenty-grain doses. When this fails, fifteen-grain doses of alcohol usually are effective. In these cases cold applications to the head are also indicated. Putting the patient into a warm bath will generally be found to relieve the delirium and wakefulness and produce sleep.

DIET AND HYGIENE.

ALONZO CLARK, regarding *diet*, believes in the steady and persevering administration of such food as can be absorbed by the stomach. Milk, beef-tea, raw eggs beaten up with water and made of such consistency that they can be eaten with a spoon, and expressed beef-juice, are all of value. Where one disagrees, another is

substituted. The expressed juice of beef is obtained by cooking a piece of steak so as just to crust the surfaces, and then squeezing out the juice with a lemon-squeezer. As the disease advances, the food administered is more and more sustaining. When the stomach fails to retain food, nutritious enemata are employed.

He considers plenty of *fresh air* as of prime importance to typhoid fever patients. He always insists that a window on the side of the room opposite the patient be dropped a certain distance from the top, even in the winter season, and that the patient be protected from the draft by the use of a screen.

The *alvine discharges* are always disinfected at once. The way in which this is done is by placing in the bed-pan or vessel a half pint or a pint of a solution of the sulphate of iron, just before it is to be used.

The *bed-clothes*, as soon as they are soiled, are removed from the bed and plunged into a tub of water, which is sufficiently impregnated with carbolic acid to secure effectual disinfection.

WILLIAM PEPPER.—Milk is regarded as the best diet during the stage of catarrhal inflammation. The milk is diluted with lime-water if the curd appears in the stools. Two pints of milk and lime-water, mixed, are given in the course of the twenty-four hours.

BELLEVUE HOSPITAL.—For the nourishment of patients milk is used exclusively, and as much is allowed as the patient can take. Usually a full glass of milk is taken every hour, lime-water being added in the few cases where the milk alone seems to disagree. The proposal of Sir Wm. Jenner to substitute beef-tea for milk does not find much favor in hospital practice, but among private patients where beef-tea can be properly prepared it is often employed. The demand is now so great that two of the New York restaurants prepare it daily for the use of the sick, and are able to dispose of large quantities.

ALFRED L. LOOMIS.—As diet he allows at first only milk diluted with lime-water, and later cream and the yolk of eggs in milk.

During convalescence he regulates the patient's diet with the utmost care, allowing no indigestible article of food.

GASTRIC AND INTESTINAL SYMPTOMS.

ALFRED STILLÉ.—For *flatus*.—Flatus may mechanically interfere with respiration and so with aëration of the blood. It may also interfere with digestion. Flatus is chiefly in the colon. It is not a secretion. Neither is it caused by increased decomposition of food, for but little food may be in the intestine. It is caused by the expansion of the gas on removal of the normal pressure caused by the tonicity of the muscular coat of the intestines, they in common with all other muscles being weakened. Mineral acids—muriatic, phosphoric, aromatic, sulphuric—every four hours. When the typhoid state is accompanied by a dry skin and a high temperature, sponge with cool or tepid water (this has no connection with the cold-water treatment). If the skin is wet with sweat, keep well dried and wrap in warm blankets.

For *tympanites*.—Endeavor to stimulate the intestines by oil of turpentine externally. Paint the abdomen with oil of turpentine, and apply to it a flannel cloth wrung out of hot water. Give enemata containing oil of turpentine. Put a teaspoonful of oil of turpentine into an emulsion and inject repeatedly. In nine cases out of ten enemata do not pass the sigmoid flexure. The action is by absorption and through the blood. Enemata or suppositories of assafoetida may be given. Use frictions with lotions. If turpentine fails, and the patient is suffering from flatus, do not fail to use the ice-bladder. When pain exists from other causes than flatus, use warm fomentations.

For *intestinal hemorrhage*.—Place the patient on his back, with his head raised and his knees drawn up. Apply the ice-poultice, chiefly to the iliac region, where the

hemorrhage probably originates. Give internally lead acetate, copper sulphate, tannic or gallic acid, or, which is probably the best, gallic acid with lead acetate. Ergot by the mouth or hypodermically.

For *pain*, give morphia or opium.

For *perforation*.—Absolute rest and opium (one grain) or morphia ($\frac{1}{4}$ grain hypodermically) hourly till the patient is tranquil. Give turpentine internally. Give no food for twenty-four hours. Give a little ice-water.

ALONZO CLARK.—*Hemorrhage from the bowels* is controlled, if possible, by absolute rest and doses of the fluid extract of ergot.

In *perforation of the bowels*, the patient is placed thoroughly under the influence of opium.

Tympanites.—Cold compresses are applied to the abdomen, and covered with oiled silk. Where this fails a stimulating injection is given, consisting of one-half pint of a solution composed of Labarraque's solution, 1 part, and water 16 parts. In other cases, from 8 to 10 drops of the spirits of turpentine are given in mucilage.

Diarrhœa he manages by the following :

R. Bismuth subnit. 3j.

Morphiæ sulph. gr. j.

M. Et. in chart No. xii. div. Sig. One to four a day.

Other astringents which he has found to be of service are tr. kino, tr. catechu, and decoction of blackberry root.

PEPPER regards the specific follicular catarrh of the intestines as of great importance in the determination of the treatment. He holds that there are a number of remedies which exert a powerful influence upon this catarrh. The first of these is the nitrate of silver, which reduces the size of the enlarged follicles, relieves the inflammatory engorgement, and allays the hyperæsthesia of the nerves. So too do carbolic acid and the sub-nitrate of bismuth. He prefers the nitrate of silver, and only substitutes carbolic acid in its place when some putrid element is present. The nitrate of silver is given in quarter-grain doses four times daily. Opium in pill form is combined with the silver when the diarrhœa is excessive. From one-quarter of a grain all the way up to one grain of opium is given three or four times daily. If the bowels are constipated, belladonna is substituted in the place of opium.

BARTHOLOW, for diarrhœa, recommends tr. iodine, gtt. v., well diluted with water, in the treatment of typhoid fever. Under this—one of the German (so-called specific) plans of treatment—he says, “with proper diet and nursing, the mortality is much diminished.” The same writer, for the diarrhœa of that disease, prefers the following :

Liq. pot. arsen. gtt. ij.

Tr. opii. gr. iv.

Repeat as often as required.

ALFRED L. LOOMIS.—*Diarrhœa* as occurring early in the course of the disease, he allows to go untreated. When it comes on in the third or fourth week he controls it by means of opium.

Tympanites he relieves by the application of turpentine stupes to the abdomen.

Hemorrhage is treated by absolute rest, opium internally, and ice-bags applied over the abdomen.

DACOSTA.—*Intestinal hemorrhage in typhoid fever*.—Ergot by the mouth with hypodermic injections of whiskey, with a little ammonia, constitute Dr. DaCosta's main reliance. The dose of ergot is 20 minims every three hours. The injection is composed of from 3 to 5 drops of aqua ammonia with 30 minims of whiskey.

LARYNGEAL AND PULMONARY SYMPTOMS.

ALFRED L. LOOMIS.—*Bronchitis* he has found amenable to dry cupping and the internal administration of the carbonate of ammonium.

Laryngitis.—A small blister is applied on either side

of the angle of the jaw, and the whole neck enveloped in a poultice.

ALFRED STILLÉ.—For *bronchial trouble* use expectorants, stimulants, as ammonium carbonate. Be careful not to disorder the stomach by cough-mixture. Probably the best method of medication is by inhalation. Use in this way oil of turpentine, balsams, ammonium carbonate of chloride, and carbolic acid. In *gangrene of the lung* use free inhalations of carbolic acid; give quinia in tonic and alcohol in stimulant doses. The food throughout typhoid fever should be unirritating. Avoid all solids as long as possible, even after convalescence. When you commence to give solids, give pepsin immediately afterward, for the stomach is not used to supply sufficient gastric juice, and must be assisted. Avoid all muscular efforts.

DaCOSTA.—For *pneumonia*, turpentine internally, with morphia enough to keep the turpentine from irritating the bowels and bladder. His local treatment of the chest consists in the use of dry cups and turpentine stupes. Twelve grains of quinia are given daily. Dr. DaCosta is a strong believer in the value of turpentine in the pulmonary complications of typhoid fever. In the vast majority of such cases stimulus is needed, about eight ounces of whiskey and four ounces of wine being given in the twenty-four hours.

For *parotitis* ice is steadily applied to the swollen gland. If suppuration takes place in spite of the ice, poultices are at once applied, and the pus released by an early incision. Dr. DaCosta's internal treatment consists in gtt. xx. of the tincture of the chloride of iron every three hours, and gr. xij. of quinia, and f ̄ iv. of whiskey daily.

GENERAL POINTS.

ALFRED STILLÉ.—Typhoid fever must and will run its course under any treatment. No treatment can abridge it; but bad treatment may prolong it, or convert a favorable case into a fatal one. Many cases need no active treatment. Mild ones need only quiet, rest, ventilation, and good nursing. Support the system. Diluent drinks, soups, farinaceous food. In more severe cases several elements require treatment. First, the *diarrhœa* requires attention. Some say to cautiously encourage it, regarding it as nature's effort to throw off the poison. It is highly probable that mild purgatives in the first stage are often advantageous. My impression is very decided that this practice has both reason and experience to support it. First, use calomel, and then mild salines or oil. Use no laxatives at all after the first week. When there is constipation, use enemata. Do not use them unless the indication is evident. If an accumulation occur, remember that the colon and rectum are healthy. For excessive *diarrhœa*, use chalk mixture, bismuth grains xx. to coat the intestinal ulcers, catechu, logwood, kino, rhatany, blackberry root. Lead acetate and silver nitrate are less safe. Astringent enemata may be given, containing small portions of opium.

For *debility* in the latter stage, from nervous strain, intestinal lesions and *diarrhœa*, cinchona and its preparations are at the head as tonics. This debility may follow any severe disease, but is greatest in typhoid fever. It is not the typhoid state, but usually follows it, but may coexist with it. Stimulants, too, must be judiciously employed until food can be assimilated. They are required when the pulse is feeble, skin cold, features sunken, and patient muttering, listless, and weak.

ALONZO CLARK is in the habit of administering some mineral acid in all cases of typhoid fever—hydrochloric is that generally employed—but does not think much of the German treatment by iodine or calomel.

Bed-sores.—Nothing has been found so effectual for their prevention and treatment as a water-bed. Where this cannot be obtained, the best substitute is the padded ring, or a rubber ring filled with air.

ALFRED L. LOOMIS.—*Bed sores* are prevented by fre-

quently bathing the parts with camphor. If the sores penetrate the integument they are washed with a weak solution of carbolic acid and afterward covered with lint smeared over with vaseline.

WILLIAM PEPPER.—The poisoned state of the blood is controlled by means of quinia and salicylic acid. The latter has been found to be very valuable in this condition as a disinfectant. Quinia is given to the amount of not more than twelve grains in twenty-four hours.

Relapses are treated as first attacks. Hemorrhage is managed by absolute rest in bed for twenty-four hours, and by the administration of opium to produce absolute rest for the alimentary canal. Acetate of lead is sometimes combined with the opium in the shape of suppositories. Ergot is also very useful. The food allowed is small in quantity, and liquid.

DR. COHEN finds that large doses of quinia rather increase the *diarrhœa* and headache. His patients are sponged with vinegar and water, and abundant ice is given them to suck. Oil of turpentine in 20 gtt. doses every hour or two, in mucilage, he has found to act most beneficially. Morphia is given hypodermically in half-grain doses where the delirium is active.

DR. WILLIAM H. BENNETT reduces the temperature and strengthens the heart by 10 gtt. doses of digitalis thrice daily.

DR. LOUIS STARR controls *diarrhœa* by starch and laudanum enemata.

TYPHOID FEVER IN CHILDREN.

DR. A. JACOBI considers typhoid fever in childhood as a very manageable disease, if taken in time.

High temperature he reduces by means of the cold bath, and if reaction is not at once established he plunges the child into a hot bath, which has the effect of restoring the circulation on the surface of the body and thus enabling the blood to throw off a part of its heat. Where the child will not bear a cold bath, he bathes the surface of the body with cold water as far down as the thighs.

He regards *cold packing* of the trunk and abdomen as of great service. The child is retained in the pack until both pack and surface become slightly warm.

When the temperature is high he gives quinia—from eight to fifteen grains daily in one or two doses. If the temperature is very high, from twelve to sixteen grains are given at a dose. He always administers it in solution, and in the form of the muriate or neutral tannate.

He does not hesitate to recommend salicylic acid and salicylate of sodium in the reduction of high temperatures. He gives salicylate of sodium to a child in doses of three to six grains, three, four, or five times in the course of twenty-four hours. He has sometimes succeeded in reducing temperature by a combination of quinia and salicylic acid where both remedies failed to do so when employed separately.

Now and then he uses digitalis, in small doses, to invigorate the heart's action. Veratrum viride he does not recommend, by reason of its occasional irritant effects upon the mucous membrane of the stomach and intestines.

He believes stimulants to be especially indicated, and gives a baby one year of age an ounce of brandy or whiskey in the course of twenty-four hours. He always gives them in milk, water, or barley-water, and never alone.

Camphor he regards as an excellent stimulant, and gives from two to ten grains of camphor, in the course of a day, to a child from two to four years of age. Musk, also, he regards as a valuable stimulant. The dose for a child two years of age, is two grains, to be repeated every hour. With it he has obtained admirable results when nothing else seemed to be of any avail whatsoever. When a speedy effect is desired, he does not rely alone upon the internal use of stimulants, but proceeds at once to inject, hypodermically, ether, brandy, alcohol, or camphor dissolved in ether, oil, or brandy. He is very

careful that the solution of camphor thus obtained is not too strong, in which case the menstruum is absorbed very rapidly and the camphor is left remaining in the subcutaneous tissue.

Hemorrhage from the bowels Dr. Jacobi treats by opium and alum. In some cases he has had excellent results from the steady application of an ice-bag over the ileo-cæcal valve.

Progress of Medical Science.

MASTOPHOBIA.—Dr. Luis Suñé y Molist relates the following case in the *Revista de Ciencias Médicas* for September 25, 1883: A child, apparently healthy and of healthy parentage, was put out to nurse, and for a time seemed to thrive; but after about a week it was taken with colic, and in order to quiet it, the parents made a little bag filled with a sort of sweet biscuit and put it in its mouth. This would quiet the child and induce sleep. In a short time it began to manifest an aversion to the breast, and would refuse to nurse, although it was hungry and would take milk with avidity when fed with a spoon. There was nothing abnormal about the nipples, nor was there any stomatitis on the part of the child. Various nurses, with variously shaped nipples, were tried, but all to no purpose, for the child absolutely refused to nurse. Recourse was finally had to bottle-feeding, but the child died at the expiration of two weeks, of enterocolitis. The writer stated that he could find no explanation of this mastophobia either in labial hyperæsthesia, paralysis of the muscles concerned in suction, anorexia, change in the quality of the milk, or deformity of the nipples. He thought that the repugnance to nursing was a sort of monomania induced in the first instance by the too frequent exhibition of the *muñecas*, or sugar-teats.

THE WARM BATH AS AN AID TO PHYSICAL EXAMINATION OF THE ABDOMEN.—In cases in which an obstacle to palpation of the abdomen is offered by the hard and tense condition of its parietes and by the contractions caused by the contact of the hand, Dr. Mai places the patient in a warm bath. In a few minutes the abdominal walls become relaxed, and the examination is conducted with ease.—*Rivista Clinica*, September, 1883.

CONGENITAL TUBERCULOSIS.—Dr. Berti relates two instances in which he found advanced caseous processes in very young infants (*Rivista Clinica*, September, 1883). The first case was that of a child born before term and living nine days. It belonged to a phthisical family. At the necropsy two cavities were found in the lower lobe of the right lung; there was caseation of the bronchial and mesenteric glands, and the pleura was infiltrated with round cells. The second case was of a child born by the breech. There was very extensive gangrene of the presenting part, and a large abscess formed in the right sacro-gluteal region. The infant failed gradually, and died after twenty-six days. The autopsy revealed tubercular peritonitis and enlarged and partially caseous mesenteric and mediastinal glands.

REMOVAL OF IMPACTED CERUMEN FROM THE AUDITORY CANAL.—In cases in which a plug of cerumen cannot readily be dislodged by syringing, Dr. Baratoux advises the employment of one of the following means: 1. Pour a spoonful of warm water into the meatus twice a day, retaining it there for about fifteen minutes. 2. Drop a little warm oil or glycerine into the ear; or, 3. Put fifteen drops of a warmed solution of bicarbonate of soda (six grains to a drachm each of water and glycerine) into the ear twice a day. In this way the plug is softened and is easily removed by the syringe. The pavilion of the ear should be held upward and backward, and the nozzle of the syringe passed along the upper wall of the auditory canal.—*Lyon Médical*, No. 31, 1883.

THE TENDON REFLEXES IN TYPHOID FEVER.—An exaggeration of the tendon reflexes in patients ill with typhoid fever has been noted by Strümpell and Ballet. Dr. Pluyand, in a recent brochure on this subject, cites a number of cases in which he found an exaggerated excito-motor power present in the spinal cord. As a rule, the disorder was manifested in the tendon reflexes. But in some this condition was slight or was masked by some other phenomenon (epileptoid movements or contractions). In still others the excitability of the cord found expression in a chorea appearing with the typhoid fever and ceasing with it. There are cases, however, in which the tendon reflexes seem to be diminished. M. Petit-Clerc, in a thesis published in 1880, even regarded this as the ordinary condition in typhoid. Notwithstanding these divergences, more apparent than real, as they are due often to the methods employed in the study of the reflexes, M. Pluyand thinks it undeniable that there is a condition of increased excitability in the cord in the greater number of cases of typhoid fever. Of 100 cases, the tendon reflex was exaggerated in 58, moderate in 25, and diminished in 17 cases.—*Le Progrès Médical*, September 1, 1883.

MEDICATED TRACHEAL INJECTIONS.—At the recent session of the Association Française pour l'Avancement des Sciences, held in Rouen, Dr. Bergeron presented a memoir on the subject of the injection of medicated substances into the trachea (*Lyon Médical*, October 7, 1883.) The injection of medicated liquids into the respiratory passages below the larynx is, he asserted, very well borne by cows, horses, and dogs, and determines very slight functional trouble. It is possible to inject in this way, in man, a solution of citrate of morphia, if the needle be protected during its introduction by a trochar, so that the canula shall not become plugged up in traversing the tissues. The little operation should be practised while the patient is lying down, so as to avoid syncope. M. Bergeron has, under these precautions, made twenty-five injections in thirty-five days, with calming effect, in a patient suffering from pulmonary phthisis.

THE USE OF SULPHATE OF STRYCHNIA IN LABOR.—Dr. Emile Déghilage employs strychnine instead of ergot in dystocia due to uterine inertia. He considers that it is more efficacious in these cases than ergot. Granules are employed containing each about $\frac{1}{100}$ grain, one of which is given every ten minutes.—*Lyon Médical*, October 7, 1883.

NON-SPECIFIC VAGINITIS IN OLD WOMEN.—A form of vaginitis, occurring in women advanced in years and free from any suspicion of sexual relationships, is described by Dr. Després (*Centralblatt für Gynäkologie*, September 29, 1883.) It is dependent upon an incomplete incontinence of urine. The muscular walls of the bladder being atonic the organ is never completely emptied, and the residual urine excites a vesical catarrh. This leads to incontinence, and during sleep, particularly when the patient lies on her back, the urine trickles down into the vagina. There its presence sets up an inflammatory process, the more readily as the urine itself in these cases always contains a large quantity of pathological products.

PRIMARY ACUTE OR SUBACUTE SYNOVITIS OF THE TENDONS OF THE HAND.—Dr. Riedell calls attention to a hitherto apparently unobserved affection of the sheaths of the tendons in the hand, which he had seen several times, but whose true nature he recognized only after opening the sheaths. There is a painful inflammation in the neighborhood of the metacarpo-phalangeal articulation, speedily followed by a complete stiffness of the finger as far as the terminal phalanx. It never proceeds to suppuration. Dr. Riedel ascertained by an incision that the trouble lay in every case in a swelling of the vincula tendinum, or in a fibrinous exudation into the sheath of the tendon.—*Deutsche Medicinische Wochenschrift*, No. 34, 1883.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, December 1, 1883.

BICHAT AND THE DOCTRINE OF VITAL PROPERTIES OF THE TISSUES.

THE problem of the nature and cause of life still defies solution, although the conditions of vital phenomena are well known. Men have endeavored to throw light on the question by certain hypotheses, and these hypotheses have deeply affected the theory and practice of medicine. In fact, at the present day, one large and influential school of medicine finds justification for its name and its practice by an appeal to the supposed reciprocal relations between certain dynamical agents (attenuated medicaments) and the hypothetical vital force under conditions of derangement.¹ Stahl, who was born about the middle of the seventeenth century, may be regarded as the founder of the iatro-spiritualist system. The *anima*, according to Stahl, is a power that opposes the tendency of the material organized compounds to putrefaction. It is the *vita* which, during its active administration, successfully resists the chemical and physical forces which would otherwise pull the organism to pieces. It is the *phusis* of Hippocrates, and the *archæus* of Van Helmont. The *anima*, by negligence or want of knowledge, may originate disease. When disease exists the *anima* is the agency by which health is restored. The whole art of therapeutics then must consist in an endeavor to repress the *anima* when outrageous and arouse its powers when languid, and to assist the efforts of this principle to bring about restorative and evacuant crises. It must be admitted that the system of Stahl was barren of progressive results. It was the old notion of the essential passivity of matter which only acts as an outside hypothetical force, nature, or *anima*, moves it. This, we may remark, is a notion which modern experimental science is demolishing every day. We are learning to emphasize more and more the essential activity of all matter, a truth forced upon us by considerations drawn from physics and from chemistry.

When Glisson, two centuries ago, pronounced the words "irritability of fibre," claiming that irritability is a property inherent in the tissue, and not a principle distinct from the body, he struck the key-note of modern physiology. This irritability is called into activity by divers external influences, which Glisson called irritant causes. These latter make the properties of organic bodies manifest. The *microcosm* is in relations of equilib-

rium with the *macrocosm*, but it is continually adjusting itself to disturbing causes. The surrounding cosmos is forever acting on the organism and the organism reacts on the cosmos by movements which Glisson called contractions. No more pregnant thought was ever presented to the human mind than this, of a moving force, organic and vital, inherent in the organism, viz., irritability, which is aroused to action by excitants. According to this conception living matter is a wonderful mechanism whose movements always originate in irritant causes outside of itself.

Haller in the eighteenth century developed with rare talent the ideas of Glisson concerning irritability, and maintained that this property is dependent on the primordial constitution of the muscular fibre. He endowed the nerves with a special property which he called sensibility. Subsequent workers in biology showed that irritability and sensibility are properties, not merely of muscular and nervous tissue, but of every part of living matter. Every unit of structure, and every congeries of units is being continually acted upon by disturbing agencies in the cosmos, and is undergoing change, of which movement is an expression. Irritants may be normal, or they may be pathological. Here is the datum on which Broussais built his general pathology. Certain medicines diminish irritability and thus restore normal physiological function when deranged, others increase irritability, and hence are indicated when this is deficient.

The doctrine of the vital properties of organs—which was destined in the progress of science to replace the "faculties" of the system of Galen, the "archæus" of Van Helmont, the "anima" of Stahl—received a powerful reinforcement from Bichat in the beginning of this century. Before Bichat there had been no exact classification of the tissues and their functions. This greatest originating mind of the century divided the corporeal mechanism into its elementary tissues, and became the founder of general anatomy. His classification has been the point of departure of all subsequent classifications. He designates twenty-one tissues, but Leydig, bringing to the investigation the aid of the microscope, has reduced them all to four, which are the fundamental tissue-elements, viz.: the nervous element, the muscular element, the connective tissue element, and the cell element (*i.e.*, epithelium, blood-globules, glands).

What gave scientific character to the work of Bichat is the careful study which he gave to the properties of each of these tissues, and the fact of his having localized there an elementary vital phenomenon. Each elementary tissue represents a particular function. All the vital properties were relegated by him to tissues; the organs of the old physiology were superseded by more elementary parts, which account for the constitution and the phenomena of living bodies, as the simple elements of chemistry explain the phenomena of inorganic bodies. Bichat in the introduction to his "General Anatomy" clearly defines his stand-point: "The general doctrine of this work is to analyze with precision the properties of living bodies; to show that every physiological phenomenon is referable in the last analysis to those properties considered in their natural state; that every pathological phenomenon proceeds from their augmentation, from their diminution, or from their alteration; that every

¹ Vide Bayard's article on Homeopathy and Science in the Popular Science Monthly for October, 1883.

therapeutical phenomenon has for its principle the restoration of those properties to the natural standard from which they have departed."

The doctrine of Bichat, so grand and so simple, opened the way to new researches, to new investigations—in a word, to progress. The single idea, vital properties, properties of tissue, provoked minute investigation into organs, and gave a powerful impetus to experimental physiology. Speculations about mysterious causal entities were abandoned as fruitless and as useless, and as calculated to put a check on investigation, and the secrets of life were sought in observation of phenomena and in experimentation. Therapeutics derived an important stimulus from the new teaching; the aim and art of medication being now summed up in a few words, viz.: the restoration of the altered vital properties of the part affected. In calling the attention of physicians to the seat of the ailment, in insisting on the material alterations which characterize disease, and the necessity of restoring deranged function, and in creating the science of morbid anatomy, Bichat, though he died at the youthful age of thirty-one, has earned for himself the gratitude of the present and all future time. It was now possible to localize morbid lesions in special tissues, and the autopsy, for the first time in the history of man, became fruitful in useful results. We can now complete the natural history of disease (founded by the school of Hippocrates) by the pathological lesions.

Bichat's fundamental classification of the functions of the human body into functions of organic or vegetative and functions of animal life, has been adopted by most physiologists, and expresses an important truth. The larger part of our physiological processes are unconscious and involuntary; the animal life, or the sensory, conscious, voluntary life, is something as it were super-added to the organic or vegetative. And yet these are not *two* natures which have taken possession of us, but only *one*. The conscious mental life is only a higher development of the unconscious bodily life. The unconscious organic life is continually obtruding itself into the sphere of the conscious, and what was once conscious and voluntary, becomes organized as habit, and takes its place among the profundities of our organic unconscious nature. Bichat, moreover, erred in treating nutrition as a *function* of organic life. Nutrition is not a *function* of living matter, it is *living*. "*Se nourrir c'est vivre*," says Claude Bernard. The opposition or contrariety between life and death which Bichat predicates in his celebrated definition—"Life is the sum of all the functions which resist death"—does not exist, for in every living substance destructive processes are simultaneous with constructive, or organizing. It is a sort of elemental strife to which a whirlpool offers a faint analogy. Flourens did in fact apply the term "vital whirlpool" to the fundamental process whose two sides are organization or nutrition, and disorganization or denutrition. An acute and philosophical thinker in recent numbers of the *American Naturalist* (February and March, 1883) has shown how absolutely dependent are all the vital processes on oxygenation. Life forever swings between limits of chemical analysis and synthesis. Oxygen eats into and breaks down the complex molecules of protoplasm; nutrition rebuilds those molecules

(nutrition, according to this writer, is simply organic chemical affinity). Nutrition locks up energy in the molecules produced. By oxygenation the stored-up energies of the body are set free and used as animal activity.¹ This is doubtless the highest view of the fundamental fact of life which inductive science yet offers, and has been concisely expressed in the definition of De Blainville, which is essentially the same as that of Letourneau—"Life is a double internal movement of composition and decomposition, at the same time general and continuous."

What Bichat lacked was a knowledge of the elementary principles of biology, a science which has undergone great development in our own times, and a knowledge of which is so essential as the ground-work of physiology and medicine.

If the study of morbid anatomy received an immense impetus from the labors of Bichat, the science of histology has been almost created since his day. If diseases must be studied in alterations effected in the tissues and fluids, then let us resolve these substances into their elementary parts and ascertain how the individual units are affected. The simple rude lens of Lenwenhoeck and Malpighi has been gradually evolved into the compound microscope, which has in our day revealed the cellular structure of all organic animal and vegetable tissue.

The next step was the development of histology on the basis of the cellular doctrine, and the cellular pathology, for which we are so much indebted to Virchow.

The field of vision has been extended to the infinitely little. To fix the disease in a cell, or in a group of cells, is, as Jacobi has said in this journal, "the finest localization possible."²

It is plain, then, that if we would understand disease we must understand the vital properties of the tissues in health, and under conditions of derangement, and the art of the therapist must be to restore those altered vital properties; and this will be the aim of every rational system of medicine.

THE BACILLUS WAR IN PARIS AND VIENNA.

A MOST animated discussion upon the subject of micro-organisms took place recently in the leading medical societies of two great European cities, Paris and Vienna. The opinions announced are of especial interest as showing the earnest skepticism that still exists among many prominent medical scientists as to the real significance of micrococci, bacilli, and the like.

In the Academy of Medicine, on October 30th, M. Bouley made a report of a commission, consisting of himself and M. Vulpian, upon the experiments of MM. Bouchard, Capitan, and Charrins, with the supposed germ of glanders.

M. Bouley's report completely confirmed, he said, the claims to the discovery of the microbe of this disease. It had been captured, cultivated to the fifteenth generation in flasks of bouillon, then inoculated again, with the production of glanders.

After M. Bouley had finished, M. Colin arose and in

¹ Organic Physics, by Charles Morris.

² THE MEDICAL RECORD, September 23, 1882.

the most emphatic manner denied the validity of the conclusions announced. There was no proof, he said, that a specific organism had been isolated and cultivated. The virus of glanders is not easily destroyed; and Bouchard's experiments only showed that it could be carried through fifteen dilutions of beef-tea! He did not deny that possibly bacteria might *carry* it.

M. Colin then proceeded to attack other alleged discoveries of specific organisms. "It is not true," he said, "that any bacteria exist in the blood of living horses suffering from typhoid. They simply develop a few hours after death, and their appearance is the result of decomposition. M. Pasteur has announced to the Académie that typhoid fever is inoculable. This too is an error."

He concluded by saying: "Is virulence attached to bacteria? Yes, probably. Is it attached to other formed elements in virulent matter? Yes, just as probably. Further: virulence exists in liquids where there are no formed elements. Where, then, does the special virus necessarily reside? We do not know!"

M. Bouley here interrupted the speaker, saying that M. Colin used phrases, while he invoked facts. He had seen the experiments of Bouchard and their results.

"You invoke facts," replied Colin, "which are only fictions. Your fifteen cultivations, for example, are myths. I have never been able to obtain from M. Pasteur any except liquids of the first and second culture, and I have always found in these other formed elements than the special microbes. Besides, M. Pasteur has always kept secret the methods of manipulation which he practises. Only his intimates know them. I have recently met savants who came all the way from Russia to learn his methods, and had been refused. This is the procedure of quacks, not of scientific physicians! I have heard much of the bacillus of tuberculosis and the preparations of M. Cornil. They show nothing as regards the specificity of the tuberculosis. These organisms have been found in the non-tuberculous."

M. Bouley here interrupted the speaker again, and a fierce altercation ensued, which compelled the President to interfere.

Turning now to Vienna, we find here also a sharp warfare of words occurring at a meeting of the Society of Physicians of that city. In this case the bacillus tuberculosis was the subject of controversy, and that blue-tinted organism sustained the attacks upon it rather better than did its bouillon-cultivated congeners of Paris. Dr. Heitler presented a paper upon the diagnostic and prognostic significance of the bacillus tuberculosis. He stated that in a very wide series of examinations he had found the bacillus always present in the sputa of the tuberculous, and never present in that of the non-tuberculous. He had also found a certain relation between the number of bacilli and the intensity of the morbid process. Dr. Heitler attacked Spina's views and experiments, and defended those of Koch.

Dr. Jakisch reported the result of some experiments in harmony with those of Heitler.

Prof. Kundrat defended Spina, and asserted that the tubercle bacillus had undoubtedly been found in cases of bronchitis, pneumonia, etc. He recalled to mind a case occurring in Nothnagel's clinic last spring, where

the bacilli were found in the sputa. Upon a subsequent post-mortem examination there was found only bronchial catarrh with bronchiectasis. A second case occurred in Schrötter's clinic. In the patient's sputum were found the most beautiful bacilli, but on post-mortem there was only bronchitis and emphysema.

Dr. Jakisch intimated that in these few individual cases there might have been errors of observation, or that sputa might have got mixed, a suggestion which Kundrat sharply repudiated.

Dr. Weichselbaum thought from his numerous examinations that the presence of bacilli was an evidence of tuberculosis. He had never found the bacilli in the secretions of non-tuberculous persons. He admitted the accuracy of Kundrat's reported cases, and said that some bacilli have such a similarity to those of Koch, that additional tests may be needed.

Thus the matter stands. The accuracy of Pasteur's cultivation method is strongly questioned, and the validity of many of his results made a matter of serious doubt.

The bacillus tuberculosis of Koch has congeners so like it that staining methods alone seem insufficient in all cases positively to distinguish it. There appear to be non-tuberculous diseases in which this bacillus may sometimes be found. Though always discoverable in genuine tuberculosis, the number of bacilli is not always a test of the intensity of the disease.

Such seems to be the condition of the bacillus problem at present. Doubtless before long, new evidence will be furnished that will change the aspect of affairs.

We ought to add that the theories of Dr. Gregg, who regards micro-organisms as fibrinous products of decomposition, are unworthy of serious attention.

THE HEALTH OF CHINA AND ITS RELATION TO THE QUESTION OF FILTH.

FROM the medical reports of the Imperial Maritime Customs for the half-year ending September 30, 1882, some very interesting statistics are obtained relative to the prevalence, etc., of epidemic diseases among foreigners and natives in China. The local peculiarities of disease, and diseases rarely or never encountered in China, are also commented upon. A meteorological table also accompanies each of the several reports.

At Chefoo several cases of fever resembling in character that of typhus, although differing from it in some particulars, occurred, chiefly confined to the Chinese, only one foreigner having been affected.

In Ichang, although nature has endeavored to compensate by the surrounding country, yet the absence of the most simple sanitary precautions on the part of the natives is a source of the greatest danger. Night-soil is carried through the streets in open baskets at all hours of the day, nevertheless the privies never seem emptied, and the odors that emanate from them and from the vegetable gardens are simply sickening. Notwithstanding this, however, with one exception, there have been no serious cases of malarial fever or dysentery among the foreign residents of Ichang, and epidemic diseases, save small-pox, are unknown. As a rule the native population is apparently sturdy and healthy. The plague of parasites and of parasitic diseases, which is universal, is due to their dirty habits rather than to their vices.

At Kiukiang the health of foreign residents has apparently been very good, excepting during the last two months of the period mentioned, when an unusual amount of sickness occurred. This was ascribed to the heavy rainfalls and floods, when cases of intermittent fever and of dysentery were especially prevalent, due, as presumed, to the decaying organic matter left by the flood, as well as to the putridity of the water itself where it was stagnant.

In Ningpo the impending unhealthy condition of the community was happily anticipated by the enforcement of careful sanitary regulations, cleaning out of drains, etc., and the general administration of quinine.

At Amoy the health of the foreign population was fairly good, and epidemic diseases quite absent from the port. Canton also shows a record of general good health, particularly among foreigners. In other portions, however, in Yangchow, Soochow, etc., cholera raged with great violence.

On the whole—that is to say, while remembering the unsanitary condition of the natives, the abundance of filth, in many cases of months' or of years' standing—the prompt measures adopted by the several medical authorities deserve especial commendation, inasmuch as where rigidly enforced the mortality, not only of the foreign, but particularly of the native community, from epidemic diseases has been very materially lessened.

We have presented editorially the general health report of the various ports of China, believing not only that much valuable information may be derived from its account, but that an inferent bearing may also rest upon our own sanitary affairs at home.

THE NEW SURGEON-GENERAL OF THE ARMY.

THE appointment by the President of Colonel Robert Murray as Surgeon-General of the Army will be received with satisfaction, not only by the Medical Corps but by the profession at large. He brings to his responsible office all the requisites of an old and well-tried member of the Army Staff. He has served during his long career in every capacity as surgeon in the army and is practically acquainted with all the details of his department which now fit him for its chief. Aside from this he was in the direct line of promotion and his appointment must be viewed as an indication on the part of the President to honor the claims of those who by long and faithful services work their way to the front.

The best assurances that as Surgeon-General he will discharge the duties of his office faithfully and well are to be found in his previous honorable record as an officer of the army, his high moral character, and his well-acknowledged professional accomplishments.

MEDICAL MISSION TO CENTRAL AFRICA.—The Guild of St. Luke, of London, have undertaken to send a medical missionary to Central Africa to carry on the medical work of the Central African mission. Dr. Petrie has been selected, and guaranteed \$1,000 for three years, by which time he will be pretty certain to be dead, if past experience teaches anything.

News of the Week.

A PROPOSED MONUMENT TO DR. J. MARION SIMS.—Dr. Harvey L. Byrd, of Baltimore, very properly suggests that an enduring memorial, worthy of his name and fame, should be erected to Dr. Sims in the Central Park of New York, the city with which they have been so intimately associated for a quarter of a century or more, and thus known throughout the hemispheres. The plans and details necessary for the accomplishment of the proposed work can be easily arranged hereafter.

THE AMERICAN RHINOLOGICAL ASSOCIATION is the name of an association organized in St. Louis recently, with a membership of twenty, representing six States. Dr. T. F. Rumbold was elected President; Dr. H. Marks, of St. Louis, Secretary.

THE CHOLERA IN BEIRUT, SYRIA.—The United States Consul at Beirut has sent an account of the appearance of cholera in that city during the past summer. It appears that after the breaking out of cholera in Damietta, last June, a quarantine was established against arrivals from Egypt. Persons quarantined were placed in a large lazaretto near the city, where they were subjected to very unfavorable hygienic conditions. Despite this fact only four cases of cholera appeared in the lazaretto, and strangely enough the disease did not spread. A few cases occurred outside the lazaretto, but neither did the disease spread here. It has been asserted that the cases were not true cholera. If they were it is difficult to explain why the disease did not spread.

COLLEGE OF PHYSICIANS AND SURGEONS OF CHICAGO.—Dr. Frank O. Stockton, of Newark, N. J., has been elected to the professorship of Diseases of the Nose and Throat in this College.

DECREASE OF PHYSICIANS IN AUSTRIA.—Commenting upon a newspaper statement that there was an excessive increase in the supply of medical men by the Austrian universities, the *Allgemeine Wiener Medicinische Zeitung* says that the average number of graduates in medicine, yearly, from all the Austrian schools, is about two hundred. The annual number of deaths among physicians in Austria is over three hundred and twenty. It does not appear, therefore, that there is an increase in physicians, but rather the contrary.

THE PRESBYTERIAN HOSPITAL AMBULANCE.—The Presbyterian Hospital has the finest ambulance in the city, and the swiftest ambulance horse.

THE RESPONSIBILITY OF EMPLOYERS FOR THE PAYMENT OF MEDICAL SERVICES TO THEIR EMPLOYEES.—A case of interest to physicians was recently decided in the Baltimore City Court. A lady sent for a physician to attend her nurse, who was sick at the lady's country residence. The nurse failing to pay the bill it was sent to the lady's husband, who also refused to settle it. The doctor then brought suit against the gentleman, and the court held that he was responsible for the payment for medical services rendered his employee, the doctor having been sent for by the wife, who had the right to make her husband responsible for the services rendered.

Reviews and Notices.

MEDICAL EDUCATION AND THE REGULATION OF THE PRACTICE OF MEDICINE IN THE UNITED STATES AND CANADA. Illinois State Board of Health. 1883.

THE industrious energy of Dr. Rauch, secretary of this board, has produced a work of great usefulness to the profession. It consists of a compilation of the laws regarding medical practice in Canada and in all the States of the Union where such laws exist. The number of physicians in each State in proportion to the population is also given. The list of medical colleges not recognized by the board, here published, has already been widely circulated.

By a typographical error on page 175 the total number of physicians in the United States and Canada is made to read 60,410 instead of 90,410.

ELEMENTS OF HISTOLOGY. By E. KLEIN, M.D., F.R.S. Illustrated with one hundred and eighty-one engravings. Philadelphia: Henry C. Lea's Son & Co. 1883.

THIS work is intended as a manual for medical students, and is written in a simple and, as far as possible, non-technical style. Although an elementary work, it is by no means a superficial or incomplete one, for the author presents in concise language nearly all the fundamental facts regarding the microscopic structure of tissues.

Regarding the mooted question of "reticulated protoplasm" Klein is rather non-committal, stating that this structure is observed "on very careful examination with good and high powers, and especially with certain reagents, in many instances."

The illustrations in the book are numerous and excellent. We commend Dr. Klein's "Elements" most heartily to the student.

THE MEDICAL STUDENT'S MANUAL OF CHEMISTRY. By R. A. WITTHAUS. Pp. 370. New York: William Wood & Co. 1883.

PROFESSOR WITTHAUS in adding another text-book on chemistry need make no apology for increasing the already long list of works on this subject, although he modestly claims that the book "is intended solely for the use of a class of students whose needs in the study of this science are peculiar," since it is well known that new facts are constantly being contributed to the literature of this branch of science, and that now and then the subject needs the revision of such a fresh and able worker as the author of this book. Moreover, his experience as a teacher in chemistry and its applications to science specially fit him for the work in hand. In the preface the author says: "While the main foundations of chemical science, the philosophy of chemistry, must be taught to and studied by all classes of students alike, the subsequent development of the study in its details must be moulded to suit the purposes to which the student will subsequently put his knowledge. And particularly in the case of medical students, in our present defective methods of medical teaching, should the subject be confined as closely as may be to the general truths of chemistry and its applications to medical science." Professor Witthaus has had exceptional opportunities in the pursuit of his studies in Germany and France, and here in his own country he has established a wide reputation both as a teacher and as an expert in toxicological and physiological chemistry. In the preparation of the manual under review the author has excluded as far as possible, "without detriment to a proper understanding of the subject, those portions which are of purely technological interest," while "chemical physiology and the chemistry of hygiene, therapeutics, and toxicology have been dwelt upon."

In the first part of the work the principles of chemical science are treated of, but an extended study of

chemical physics is purposely avoided, except in so far as is absolutely requisite to a proper understanding of the subject—the more extended study of physics belonging rather within the domain of physiology than of chemistry.

The second part treats of special chemistry, where the author has departed in certain respects from the methods usually followed: thus the elements are classed, not in metals and metalloids, which he regards as arbitrary and unscientific, but into classes and groups according to their *chemical* characters, and "in the text the formula of a substance is used in most instances in place of its name, *after it has been described*, with a view to giving the student that familiarity with the notation which can only be obtained by continual use."

The third part of the work is devoted to those operations and manipulations which will be found to be of utility to the student and physician. Physicians will find in this useful manual practical directions for the examination of calculi, and of simple chemical compounds, and quantitative methods of interest to them are also described. The methods recommended are simple, and the ones best adapted to the limited facilities of the general practitioner. Although no special claims are put forth in respect to the value of the work upon analytical chemistry, the author has "endeavored to bring that branch of the subject rather into the foreground so far as it is applicable to medical chemistry." The metric system has been followed throughout the book; but in deference to those who prefer to retain the old method, troy and apothecaries' weights have been introduced in brackets, and the value of degrees in Fahrenheit have likewise been made to follow the Centigrade. Wherever necessary illustrations have been introduced, and there are a large number of useful formulas and tables contained in part third, which is devoted to laboratory technics. The make-up of the book is good, the type plain, and it is altogether a credit to the publishers.

TRANSACTIONS OF THE AMERICAN OTOLOGICAL SOCIETY. Sixteenth Annual Meeting, July 17, 1883. Vol. III., part 2. Published by the Society. New Bedford, Mass.: Mercury Publishing Company, printers.

UNDER the efficient management of the Secretary, Dr. J. J. B. Vermyne, the transactions of this society are given to the public within three months from the date of the annual meeting. The volume contains papers read by Drs. Holt, of Portland, Me.; Knapp, of New York; Todd, of St. Louis; Kipp, of Newark, N. J.; Seely, of Cincinnati; Sexton, of New York; Andrews, of New York; McKay, of Wilmington, Del., and Burnett, of Philadelphia, together with thirty pages of discussions which they elicited. The papers and the discussions do credit to the society, and the volume should be in the hands of all who are interested in diseases of the ear.

TABULÆ ANATOMIÆ OSTIOLOGIÆ. Editæ a CAROLO H. VON KLEIN, A.M., M.D. Cincinnati, O. 1883.

THE author of the work before us is, perhaps, somewhat of an enthusiast, but the work itself is very good, and gives evidence of a vast amount of labor. The book comprises thirty-two plates, presenting severally the various groups of bones forming the human skeleton. The various names, etc., are given in Latin only, one of the objects of the work being to present a language which shall, especially in its technical expressions, become universal among the profession. Regarding the execution of the work, we do not think that the drawings, or more particularly the engravings, show as much practical knowledge on the part of the artist of the subject in hand as such plates should exhibit, e.g., in the plates representing the occiput; while for an excellent fine line engraving the work deserves much credit, yet this has been allowed to supersede the object in view, and even in this respect the lights and shades are in many cases met too suddenly for the faithful representation intended. Hence we would suggest far more accurate drawings and less fine execution. Moreover, some of the plates are simply impossi-

bilities anatonically, or strange anomalies, evidently through fault of the engraver.

The adoption of an universal language, however, *i.e.*, the Latin, as is suggested, and which the author would achieve for all the medical world, would, it is feared, hardly be sustained so long as our American medical machines continue so prolific in their grinding. And although we should highly endorse our friend in his esteemed labor, yet we think he should be prepared to find that the accomplishment of his work may be doomed to disappointment.

The work is presented in very handsome form, and will be appreciated by student and practitioner alike.

THE DIAGNOSIS AND TREATMENT OF DISEASES OF THE EAR. By OREN D. POMEROY, M.D., Surgeon to the Manhattan Eye and Ear Hospital; Ophthalmic and Aural Surgeon to the New York Infant Asylum, etc., etc. With one hundred illustrations. 8vo, pp. 392. New York: Bermingham & Co. 1883.

IN the above volume the author has presented quite a valuable work on the diagnosis and treatment of diseases of the ear. To many this portion of the subject may perhaps appear too thorough, in reading the book—that is to say, to the exclusion of much valuable matter which we think ought justly to have been embodied in a work of this kind, *viz.*, anatomy and physiology, the absence of which, as the author frankly states, is noticeable throughout. The several forms of aural disease are dealt with in a manner exceedingly satisfactory. In some of the subjects the etiology is not so complete as might be wished for, but the symptomatology, diagnosis, and treatment are indeed very well presented. Prognosis is also given. In addition, the various instruments required in the examination of the ear are presented, with cuts, and instructions as to the methods of using them, etc. The author's views on the best means of examining the throat and nares are also given, together with the necessary instruments (illustrated). Various other affections of the ear are included in the work: malignant disease, syphilitic inflammation, and affections dependent on hereditary syphilis, as well as disease of the ear confined to the labyrinth or acoustic nerve. The various instruments for aiding the hearing—trumpets, the audiphone, and Japanese fan—also receive consideration. On the whole, the work is quite exhaustive in its scope, and will represent an authority on this subject which we believe will be duly appreciated by the profession.

A PRACTICAL TREATISE ON THE MEDICAL AND SURGICAL USES OF ELECTRICITY. By GEORGE M. BEARD, A.M., M.D., and A. D. ROCKWELL, A.M., M.D. Fourth Edition. Revised by A. D. ROCKWELL, M.D. With nearly two hundred illustrations. 8vo, pp. 758. New York: William Wood & Co., 56 and 58 Lafayette Place. 1883.

AGAIN is presented to our notice one of the most useful text-books of the day, of the greater value because it leads in a province of practical medicine hitherto unworked.

The many points of instruction and interest contained in the body of the work have been duly noticed in reviews of preceding editions. Thorough and careful revision adds to its former excellence. The chapter on static electricity is new, and doubtless will excite much attention, as many of the ideas advanced will be made the subject of further investigation. The crowning effort of the work, the treatment of extra-uterine pregnancy, is of inestimable worth. The literature upon this subject, until within a few years, has offered anything but a hopeful issue from this unfortunate condition. Vaginal section, gastrotomy, injection into foetal nest, etc., with attendant dangers and horrors, were to be apprehended. A series of seven successful cases is recorded. The method of treatment is simple in detail, sure in effect, causing little pain and danger, reducing the dread conse-

quences of this unavoidable complication to the minimum. The advantages to be obtained by electrolysis in regional surgery is being more appreciated to-day than ever before, and demands from the general practitioner his closest attention. A careful perusal of this work will open to him a mine of wealth, as it is exhaustive. No department of electro-therapeutics is left untouched.

For years Drs. Beard and Rockwell have labored in this department of medicine with assiduity and success, meriting the approbation of the scientific world. Dr. Beard has gone hence; may his co-worker attain to greater merit than was their privilege when together.

PRACTICAL CLINICAL LESSONS ON SYPHILIS AND THE GENITO-URINARY DISEASES. BY FESSENDEN N. OTIS, M.D., Clinical Professor of Genito-Urinary Diseases in the College of Physicians and Surgeons; Surgeon to Charity Hospital, etc., etc. 8vo, pp. 584. New York: Bermingham & Co. 1883.

THE work before us is certainly a very complete one on the subject of which it treats. The volume is divided into two parts. The first includes gonorrhœa, chancroid, and syphilis, the latter of which is minutely dealt with in every detail, including the initial lesion, hereditary transmission, diagnosis, etc. Lesson VI. presents the progress of syphilitic infection, varieties, and complications, and the treatment of the initial lesion. The early constitutional forms of syphilis are then taken up, followed by the treatment of syphilis in the acute stage. Numerous clinical cases are then given, illustrative of the various forms which the initial lesion may present, and of the various lesions associated with and following the same. The mucoid form of the lesion is also spoken of, together with clinical cases showing the results of treatment. Lesson XVII. presents the sequelæ of syphilis, gummy tumors, etc., and the various sequelæ involving the nasal and other bones, and those producing brain symptoms, followed by syphilis of infants, and hereditary syphilis. Chancroid and its nature is then taken up (Lesson XXIV.), together with its diagnosis and treatment. In Part II. gonorrhœa is very thoroughly considered, the nature of gleet and its dependence upon stricture, and the complications of gonorrhœa. Following this (Lesson XLIV.) urinary extravasation, epididymitis, and prostatitis are spoken of. The remainder of the work is almost entirely given up to the consideration of urethral stricture, its examination and treatment, and especially to spasmodic stricture. The author's views are also fully supported by a large number of clinical cases. Finally, a closing chapter is devoted to digital exploration of the bladder, by means of an incision through the perineum, as an aid to diagnosis in obscure cases. The work is very thorough in every detail, and, coming from the pen of one who has been before the professional public for many years as a teacher in this branch of surgery, will no doubt be accepted by both the student and practitioner.

INDEX CATALOGUE OF THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE, UNITED STATES ARMY—AUTHORS AND SUBJECTS. Vol. IV., E-Fizes. 4to, pp. 1033. Washington: Government Printing Office. 1883.

THE very valuable and very complete "Catalogue of the Library of the Surgeon-General's Office" has advanced to its fourth volume, and now includes authors and subjects from E-Fizes. Altogether this volume contains 4,802 author titles, representing 1,926 volumes and 3,885 pamphlets. It also includes 12,361 subject titles of separate books and pamphlets, and 48,977 titles of articles in periodicals. Too much praise cannot be accorded to Surgeon J. S. Billings, U. S. A., the accomplished librarian of the Surgeon-General's Office, for the admirable manner in which he has carried on the work of cataloguing the vast treasures of medical literature under his supervision. ☞

Reports of Societies.

NORTHWESTERN MEDICAL AND SURGICAL SOCIETY.

Stated Meeting, November 21, 1883.

MARK BLUMENTHAL, M.D., PRESIDENT, *pro tem.*

THE IMMEDIATE OPERATION FOR LACERATION OF THE PERINEUM.

DR. R. C. M. PAGE read a paper on the above subject (see p. 590).

DR. W. T. LUSK was invited to open the discussion, and said he was in full agreement with the author of the paper with regard to the practice advocated, and yet he had been so slowly converted that perhaps it might be interesting to relate his experience, and how it came to pass that he regarded the immediate operation as the proper one to perform under the circumstances indicated in the paper. In 1871 he began his service as obstetric physician in Bellevue Hospital, and at that time a great deal was being written in Germany concerning the immediate operation. He therefore began the use of the method somewhat enthusiastically, but after having failed in quite a number of cases abandoned it entirely. When, a little later, Dr. Noeggerath read a paper before the New York Academy of Medicine on this subject, Dr. Lusk formulated his objections to the immediate operation, and there stated that it rarely succeeded; that it was difficult to estimate the extent of the lesion at the time of delivery, and that many patients were subjected to operations in whom it would not have been found necessary subsequently. He also stated at that time that it seemed to him the cases for immediate operation should be limited to those where the head was born soon after the beginning of the second stage of labor, before it had occupied the pelvic cavity for a long time, and before pathological changes had taken place in the tissues below the child's head.

In estimating the extent of the laceration, Dr. Lusk thought the method of putting one finger into the rectum and the thumb into the vagina, even where the rent was quite extensive, was not very satisfactory. He did not believe that spontaneous union takes place very often to more than a limited extent, but he thought there were many cases in which we fail to recognize the slightness of the injury inflicted.

Continuing his experience, he said that later on, in private practice, he was introducing the sutures into a ruptured perineum about three hours after the birth of the child, and suddenly he was flooded with blood. The patient had a violent hemorrhage, which he regarded as undoubtedly due to the excitement produced by the operation. He therefore reached the conclusion that it was not only unnecessary, often did not succeed, but that it was not entirely devoid of danger. However, later, as he adopted the operation in private practice, he was more favorably impressed with it, and had found that healing had taken place readily, that the patients were up and about on the tenth or twelfth day, and he was encouraged to try the operation once more in hospital practice. At the Emergency Hospital all his operations were entirely successful for a time, but at Bellevue Hospital only about half of the operations were successful, and it was not very satisfactory. He then reached the conclusion that all emergency cases would do well, but not long afterward the operation failed in all the emergency cases. Again reviewing the situation and studying the cases, he reached the conclusion that at times all cases would fail; at other times all cases would succeed, and that the results depended altogether upon atmospheric conditions and the condition of the lochia. If the atmospheric conditions are unfavorable, and the lochial discharge undergoes decomposition quickly and extensively, the operation wounds will not heal.

So far as the operation itself is concerned, he had advocated the use of Peaslee's needle, and thought it the best that could be used in the treatment of cases where the rent does not extend through the sphincter ani nor up the septum. A very prominent reason why he employed Peaslee's needle was because it did not break.

Recently, in looking over his hospital obstetric record, he found that he had operated in twenty-four cases, twenty-three of which were successful, and in one there was partial failure, due to a certain amount of carelessness with which the operation was performed. He thought it not of any special advantage to compare the primary with the secondary operation. The question is not whether the secondary is more dangerous than the primary. The primary has been so successful in a large number of cases, and is so simple in its performance, and does so much to prevent the woman from suffering during child-bed, avoids suffering for weeks or months before the secondary operation is performed, that it seemed to him there could be no doubt with regard to the propriety of the primary operation. He must say, however, that not all cases of slight laceration necessitated the introduction of sutures. He thought it very probable that if in obstetric practice we were a little more careful in the observance of some of these little points much more suffering might be alleviated than is now the case.

DR. W. GILL WYLIE said his experience had been confined almost entirely to the secondary operation, but he agreed with Dr. Page in advocating the immediate operation. There are a certain number of cases where there is only slight tearing, so far as the skin or mucous membrane is concerned. Yet there occurs a subcutaneous rupture or stretching of the deep pelvic fasciæ that are united to or at the perineum, or dilatation and separation of the posterior wall of the vagina takes place, which would not always be relieved by the immediate, and are sometimes difficult to remedy in old cases by the secondary operation. It will soon be a recognized fact that, so far as the position of the uterus is concerned, the perineum can only indirectly affect it; for the perineum is not a support to the normal uterus, but when partially torn through may allow fecal matter to crowd forward the posterior wall of the vagina, and, by distending it, cause the vagina to pull the uterus downward and backward. His experience had been, that displacement, especially retroversion, is much more likely to result from a partial rupture involving the inner or upper angle of the so-called "triangular body" than in those cases where the whole sphincter ani has been completely destroyed. In five out of six cases that he had operated upon in the past year, where the sphincter was destroyed, only one had retroversion, and, although in two of the others there was some general prolapse, yet neither the position nor condition of the uterus made the operation necessary; it was done to restore the sphincter. He knew of one woman, the mother of six children, who had the sphincter and vagina lacerated nearly to the uterus with the first child, and they still remain so, yet the uterus is in nearly the normal position. He believed, therefore, that the most important part of the perineum is that where the vagina joins it and keeps back the fecal matter as it descends the curves of the sacrum, deflects it backward toward the anus, thus preventing it from pushing forward and distending the vagina, and indirectly displacing the uterus downward and backward. In these cases the ordinary operation is only a partial success, and the "clover-leaf shape," where the central part represents the denuded rectocele, and the lateral the two sides of the vulva, will often result in what he called a skin-flap perineum. The most important part to denude and to reunite is the depressed angles on either side between the central and lateral parts of the clover leaf. They are the most difficult to denude and to bring into close apposition, yet when they are together the rectocele is depressed backward and the sphincter ani pulled forward, and thus the fecal matter is deflected backward

out through the anus. He does not sew the depressed angles up separately, as recommended by Dr. Emmet, but brings them into apposition.

As to statistics, many cases reported cured are merely skin-flaps that look well at the time, but soon stretch and yield so much that the patient is left in as bad a condition as before the operation. No one has a right to claim a cure until six months or a year or two has passed, and time and use have tested the result. In his argument for the immediate operation, Dr. Page did not speak of the bad influence of time in bringing about atrophy and degeneration of the torn and disused tissues composing the perineum. This is important, for on this account such cases are more difficult to treat and secure the best results. This atrophy and loss of tone account for the severe cases of procidentia, which so many even to-day consider incurable, yet when carefully operated upon can almost all be cured by denuding deeply and bringing the parts together well up in the vagina.

He would like to ask if Dr. Page recommended constipating the bowels after operations.

DR. PAGE: No, I merely said that it may be done, but I regard it as bad practice.

DR. WYLIE thought if the doctor analyzed his hospital statistics he would find that the failures (immediate failures) were due to the old practice of constipating the bowels. To-day primary union should be secured in nineteen out of twenty of all cases, but to do so the bowels must be moved every day.

DR. McLAURY referred to a case in which union was complete, but a dose of castor-oil swept the results of the operation away completely.

DR. W. R. GILLETTE said that some years ago he went on record as opposed to the immediate operation, and the opinion which he then gave was based on his experience in quite an extensive practice in the Maternity Hospital on Blackwell's Island. Since that time, however, he had been performing this operation invariably in private practice, and must say that he would as soon leave a woman without the ordinary attention which the accoucheur gives her as to omit repairing the perineum at once, if he found that any laceration whatever had occurred, no matter how slight. He believed it necessary to stitch up every rent, and in that respect he disagreed with Dr. Lusk. It was not for the purpose of sustaining the uterus or other pelvic organs, as he had not so much belief in the perineum as a sustaining body, as "the keystone in the arch," as many of his friends seem to have, although it was sometimes a very important factor in results obtained. What occurs as a result of trivial lacerations is an enlargement of the ostium vagina, which is of considerable psychical importance. He preferred silver-wire sutures, because if on examination at the end of the first, second, or third day, it were found that the parts were not closely coaptated, another twist could be given the sutures. Another point which he regarded as of special importance is the introduction of deep sutures, and he made it a rule to go as deep as possible.

DR. JAMES L. LITTLE agreed with the author of the paper concerning the propriety of the primary operation. He had not been in the habit, however, of sewing up every laceration. He did not believe that primiparas could be delivered without a certain amount of laceration taking place, and he did not regard an operation in those cases as necessary. Dr. Page had expressed the opinion that when laceration occurs, it almost always takes place with delivery of the head, but Dr. Little entertained the opinion that the shoulders did the tearing, and cited a case in illustration, in which after the head was born there was sufficient delay to give opportunity to inspect the parts carefully, and no laceration whatever had occurred. But after the shoulders were delivered it was found that laceration to the extent of an inch or more, had taken place. It had been his custom to use silver wire for the deep sutures.

DR. A. M. JACOBUS reported a case in which spontaneous union of the lacerated perineum had taken place. The woman was twenty-six years of age, a primipara, and there was complete rupture with post-partum hemorrhage, but union of the laceration occurred by first intention *without* an operation. A few bleeding vessels were twisted, the parts were cleansed with the utmost care, all clots were removed, and the lacerated edges were carefully approximated, the woman placed upon her back, and the knees tied together. The urine was drawn with the catheter. On inspecting the parts on the second day it was found that union by first intention had taken place throughout.

DR. S. BARUCH thought the paper and remarks made by the gentlemen were of special importance to the general practitioner, because they confirmed the view that the accoucheur is responsible for a large number of ugly deformities which are seen after parturition. He regarded it as criminal for any physician to leave a case of labor without examining the genitals of the woman. Both primiparæ and multiparæ should be examined, the latter by the finger and the former with the eye and a good light. There is no procedure from which he had derived more gratification than the primary operation for lacerated perineum, and he had found but little difficulty in getting the consent of the patient and her friends for the performance of the operation. He believed with Dr. Gillette, that every laceration should be repaired, no matter how slight, and regarded silver sutures as the best. It had been his custom to use a compressed shot to hold the end of the suture and cut it short. He had the urine drawn regularly, and used carbolyzed injections.

DR. EDWIN F. WARD favored the immediate operation, and said that it had been uniformly successful in his hands. He had always employed the silver-wire sutures, except in one case.

DR. W. FRUITNIGHT reported a case, that of a woman twenty-six years of age, whom he delivered with forceps. The parts were œdematous, complete laceration of the perineum occurred up as far as the internal sphincter. Post-partum hemorrhage occurred, and also hemorrhage from the perineum. In this case the condition of the patient was such that he did not think it admissible to undertake to perform the operation. He therefore cleansed the parts thoroughly, kept the patient upon the back for two days, and afterward alternated her position from the side to the back, and syringed the vagina with carbolyzed solution. Sloughing of the vagina upon the lateral walls occurred, and subsequently the temperature rose to an extent which made him believe that there was some decomposing material within the uterine cavity, and he resorted to intra-uterine injections with immediate and permanently beneficial effect. The case then progressed favorably, and on the eighth day it was found that the perineum was completely united. At the end of three and a half weeks the woman was about her room, and experienced no inconvenience whatever from inability to control either the feces or flatus.

DR. CHARLES S. WOOD stated that his experience did not confirm that of most of those who had already spoken. He had had occasion to see a good many cases of labor in the course of thirty-five years, and had not been in the habit of performing the primary operation. In cases of extensive laceration, extending to the rectum, he should perform an operation, but it was questionable whether or not he would perform the primary operation; for he had seen cases in which union had occurred and had been as perfect as could be obtained by any operation. Besides, lacerations to the first or second degree almost invariably recover, leaving the parts in as normal condition as they ever are after childbirth. He had been particularly interested in the remarks made by Dr. Wylie, as he had had occasion to see more injurious effects, more broken-down women, in cases where there was no actual rupture of the perineum than where there was, and was pleased to hear the facts expressed as they had been by Dr.

Wylie. He had seen but few ill results following rupture of the perineum without operation. He believed, if in every instance we should examine the parts, find what might be called rupture of the perineum, let it alone and examine subsequently, it would be found that the apparent laceration had passed away. This condition is not a real laceration, but an apparent laceration due simply to relaxation of the parts.

THE PRESIDENT said that during a practice of thirty years it had been his fortune to see comparatively few cases of laceration of the perineum. He made it a special point to be very careful of the perineum, and remembered only two cases in which complete rupture took place into the rectum. One of these passed from under his observation, but in the other the secondary operation was performed, and successfully. In all the other cases in which laceration had occurred the injury had been slight, and his practice had been to stitch them together at once, whether the rent was a half inch or an inch and a quarter in extent, and as a rule no trouble had followed.

With regard to the chances of over-estimating the damage done, he thought it was not easy to say how much the injury really is, and related a case in illustration, that of a primipara, advanced in years, who was delivered with forceps, and notwithstanding the attention which three attendants could give her, there was a laceration, as it seemed to him into the rectum. No operation was performed, on account of the condition of the patient. The result was that when two weeks afterward a final examination was made he found the wound entirely closed, except, perhaps, for three-quarters of an inch at the posterior end of the vulva, where he introduced a suture more for the purpose of hastening a cure than from necessity. In this case the two gentlemen who were assisting him insisted that the immediate operation should be performed, but he did not approve of it on account of the condition of the patient, and the result was as stated. Of course it went to prove that we might over-estimate immediately after labor the actual damage done. But while he recognized that fact, he was fully convinced of the other fact, that in the majority of cases, where laceration is not so extensive and does not involve the sphincter ani, it is still wise to make the primary operation at once and support the perineum.

DR. MCLAURY believed with Dr. Wood that many of these cases would heal spontaneously.

DR. COLE had found that slight lacerations, those not extending more than half way down, got well by strict observance of cleanliness and position of the patient quite as favorably as with the operation.

DR. PAGE, in closing the discussion, said that he had not, nor did he ever expect to use Peaslee's needle; that he thought there was no necessity for drawing the urine if the woman voided it while upon her hands and knees; that he had not seen a case where he had been obliged to tighten the sutures after one or two hours; that he stated in his paper that medicine to constipate the bowels had been recommended, but he regarded it as bad practice.

DR. GILLETTE said that Dr. Page perhaps had misunderstood him, as he did not expect to tighten the sutures in every case at the end of twenty-four hours or two days, but that he had in a few instances seen shrinking of the parts at the end of twenty-four hours, which made it necessary to tighten the sutures.

The Society then went into executive session.

THE ESSENTIAL ELEMENTS OF HEALTHY RECREATION, according to Sir James Paget, are "uncertainty, wonder, and the exercise of skill." It would be worth while to see how many of these elements enter into the conventional "Sunday excursions," so much praised by the popular press for their health-giving qualities.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Adjourned Annual and Stated Meetings, November 26, 1883.

THE adjourned annual meeting was called to order by DR. DAVID WEBSTER, President. After the reading of the minutes of the annual meeting, the

REPORT OF THE COMMITTEE ON HYGIENE

was read by the secretary. It consisted of four parts, the first part was by DR. E. G. JANEWAY, on

MORTALITY STATISTICS AND EPIDEMIC INFLUENCES.

The mortality for the nine months for the year ending September 30th has been less than for the corresponding period for 1881 and 1882. It has, however, been somewhat greater, both absolutely and comparatively, as regards increase of population, than that for the same period in the years 1878-79-80. Then followed figures showing the absolute difference for ten years.

The work of systematic vaccination was begun in 1875 and continues at the present time. The corps at the Board of Health charged with this work has performed 119,856 primary and 430,783 revaccinations. By the labors of the Board of Health the disease has been checked on all the occasions on which it has appeared. The mortality from small-pox is only one-half to one-fourth what it was in the six years preceding 1877. Physicians should urge this work, as, when small-pox has only prevailed to the limited extent that it has done during the six years just ending, the people become careless, and persuasive vaccination by public authority becomes difficult. It is far more essential to keep up thorough vaccination now than to wait for an invitation after the initiation of another outbreak of the disease, which will find its victims among the careless and the obstinate. Dr. Janeway then presented the mortality tables for measles, scarlet fever, diphtheria, etc., for the three-fourths of each year from 1872-83 inclusive. They showed the fluctuating character of mortality for measles, scarlet fever, and diphtheria, from which it seems probable that, owing to the moderate number of deaths from scarlet fever this year we should witness next year a marked increase for this disease; whereas for measles the probability would be that there would be a considerable diminution. Diphtheria is on the decline, and from the previous course of the disease it is possible that this diminished mortality may continue for another year or more. Pneumonia has produced 41 less deaths than last year, 235 more than in 1881, and 634 more than in 1880.

During last summer the mortality from diarrhoeal diseases had been comparatively moderate. From a comparison of the mortality of these affections Dr. Janeway felt that, making all due allowance for all possible error, a considerable number of lives had been saved as a result of the employment of a summer corps of the Board of Health, and of the active charity of New York City.

With regard to typhoid fever, he feared, owing to the defective water supply, a decided increase in the mortality had occurred. But for the efforts of the Board of Health the disease would have spread greatly and extended over a number of years. Physicians should see to it that the Board of Health is properly maintained, aided, and encouraged in its work. At times physicians have neglected or, by concealment, have failed to notify the Board of Health of the existence of contagious diseases, with the effect of producing an epidemic in some cases.

The second part was by DR. O. D. POMEROY,

ON SOME POINTS IN THE HYGIENE OF THE EAR.

Ordinarily the ear is not affected by exposure to the air. All tuberculous subjects, those of a strumous habit, and a considerable number who rank as peculiarly

sensitive to atmospheric influences, are exceptions to the general rule. Damp air is much more apt to act perniciously than dry air. Sea-bathing is often injurious from the direct application of the cold water to the meatus giving rise to otitis media; or, from the violent concussion of a wave upon the meatus, or the entrance of water into the Eustachian tubes. Fill the meatus with cotton and tell the patient not to inhale water or allow it to get into the mouth.

The effect of loud and discordant noises in the ear is often very pernicious. If the patient is removed from the noise before profound deafness results, he may spontaneously recover a good degree of hearing or become wholly convalescent. Riding in railway cars with the windows open, ship-calking, and confinement in the never-ending clicking noise of the telegraph instrument, may act perniciously on the ear. Musical sounds do not seem to do harm to the ears. Monotonous and discordant sounds seem alone to operate injuriously on the ears.

Cannon-firing, or the discharge of firearms, or the concussion of any explosive sounds, especially when occurring unexpectedly, is likely to do great harm to the hearing. It may rupture the drum-head, or at once render the acoustic nerve unfit for functional activity. Hold the mouth open while the gun is being fired, so that the concussion may act simultaneously upon both surfaces of the drum-membrane. The effect of compressed air, as experienced in the ears of divers, caisson-builders, etc., is often very pernicious. The principal mode of obviating such pernicious consequences is to cause a frequent interchange of air between the throat and the tympanum. This is accomplished by catheterization, either with the Eustachian catheter or Pomeroy's faucial catheter, or by Politzer's or Valsalva's operation. Sometimes simply swallowing, either with or without the stoppage of the nostrils, will be sufficient, in going from one compartment of a caisson to another having a different air-pressure.

The ears require to be "changed," as the expression is; that is, induce an interchange of air between the throat and tympanum, so as to equalize the pressure. On the score of violence inflicted on the ear, the common practice of boxing the ears of children is liable to result in serious damage; pulling and pinching the auricles is much to be reprehended. With reference to the prevention of impaction of cerumen in the meatus, disease of the ears for the most part may be predicated when this tendency exists, and no efforts at cleanliness can prevent it. *Sunstroke* occasionally affects the hearing unfavorably.

The third part was by DR. STEPHEN SMITH,

ON SEWER-GASES.

Sewer-gas has been recognized as a powerful factor in the cause of that large class of preventable affections known as "filth diseases." The writer then spoke of the solution of the question of the prevention of the entrance of sewer-gas into dwellings, of the far more important question of ventilating sewers themselves, and of the system adopted by the Department of Public Works for the accomplishment of this purpose. Dr. Smith gave practical illustrations of the evils of the present system of ventilating sewers, that is, by means of perforated covers to the man-holes in the streets. He referred especially to Forty-second Street, which is seldom free from the odor of sewer-gases, and frequently for days and nights together the odor is so intense as to raise the inquiry of the residents as to the possibility of the odor from the gas manufactory miles distant reaching them. In damp, foggy weather the residents have been obliged to close their windows at night to shut out the foul odors. He thought it very evident that this method of ventilating sewers is in every respect objectionable. Practically it is equivalent to having open sewers running through the streets of New York. There can be no effective method

of removing the gases of sewers except by apparatus which is aspirating in its operations. The gases should be drawn out by the action of forces which are constant and altogether independent of atmospheric changes, and delivered into the external air at an altitude which renders it impossible for them to penetrate any room occupied by human beings at any time. The subject above considered ought to receive the attention of the Board of Health. In answer to complaints of citizens, and requests that the nuisances be abated, that body refers to the Department of Public Works. Though the sewers are managed by that department, yet the Board of Health is not thereby exonerated from obligation to protect the public health against the dangers to life or the detriments to health which the Department of Public Works or any other department creates.

The fourth part was by the Chairman of the Committee, DR. S. OAKLEY VANDER POEL, on

THE HYGIENE OF HIGH HOUSES.

The Committee protested against the erection of high buildings from a hygienic point. *First*, with reference to the inmates. Since the inception of this question in building no general epidemic, such as all large communities are liable to, has occurred. Isolation of the sick in all such maladies is a prime factor to prevent spread of the disease. In the buildings constructed having so many families, such isolation would be practically impossible. Either through necessary attendance, contaminated clothing, or currents of air, the epidemic poison would be carried to every occupant, and the persons now eager to secure apartments therein would be as anxious to desert them. The families in the first three stories are to a great degree deprived of sunshine. The importance of this to the thickly denized population can hardly be over-estimated.

So much of the surface of the lot is occupied both for obtaining room and to give solidity to the high walls, that it becomes necessary to resort to every expedient to procure the necessary circulation of air and ventilation. Chief among these are the air-shafts running from the bottom to the top of all such houses. Into these, windows open either from the inside rooms, or these windows may serve as ventilators to water-closets and bath-rooms. While the houses and plumbing are new no unpleasant effects may follow this procedure, but, as experience has too often shown, defective plumbing in any of the lower stories will allow miasm to be wafted to every story above through the open windows upon these shafts.

For economical reasons, most of the closets and bath-rooms are placed upon one line of piping. Should typhoid fever, or possibly cholera, occur in the lower stories, and any defects exist in the traps above, the poison would contaminate the apartments so exposed.

Second.—Their influence is more baneful upon the surrounding property and streets. Opposite and adjoining houses receive no direct rays of sunshine. The streets remain damp, and of necessity more or less filthy. This constant dampness and lack of sunshine is more or less pernicious. All methods of disinfection and destruction of disease germs depend upon the active oxidizing effect of the material employed. In our streets, next to cleanliness the most important factor in oxidation is the sun's rays.

These evils are not confined to the residents of the high buildings, but to those also on the opposite side of the narrow streets. Private houses, before cheerful and healthy, become gloomy and unhealthy. Fictitious currents of air are established which not only make smoking chimneys, but may reverse the currents from the underlying pipe from the roof connecting with the soil pipe. While apartment houses in our crowded population with limited area may be a recognized necessity, a limit of height, regulated by the width of the adjoining street, should be required as a sanitary necessity.

ADDRESS OF THE RETIRING PRESIDENT.

DR. DAVID WEBSTER then addressed the Society, making brief reference to the work which had been done during the past year in the way of prosecuting illegally qualified practitioners. He was also pleased to be able to note that during the year a new interest had been aroused in scientific work. More scientific papers had been offered than the limited number of meetings of the Society could receive, and the average attendance of the meetings had increased. Notwithstanding the large increase of members, there is still room for missionary work in that direction. Since the law of 1880 went into effect it has been the rule of the Comitia Minora to recommend for membership none but legally qualified practitioners. This rule has debarred several excellent physicians who, having graduated at medical colleges *without* the State, and not having joined the County Medical Society before the law went into effect, could not become legally qualified without having their diplomas endorsed by the faculty of some duly chartered medical college within the State. These gentlemen have objected to the trouble and expense of getting their diplomas endorsed, and though they have registered at the County Clerk's Office, are still practising illegally.

DR. WEBSTER then read the names of the members who had died within the year, and referred to their work and the influence which they exerted. In conclusion he thanked the Society for the uniform courtesy extended to him while serving it as president.

THE SECRETARY read the resignations of Drs. J. H. Low, M. B. Dubois, W. Thurman, J. C. Lay, and Austin Flint, Jr., which were accepted.

The adjourned annual meeting then adjourned.

Stated Meeting.

DR. S. OAKLEY VANDER POEL, President, called the Society to order and delivered his

INAUGURAL ADDRESS,

in which, after expressing his high appreciation of the honor conferred in electing him president, and speaking of the general scope of the organization, he said that the Society had reached a period of its growth and intellectual activity when better than mere ephemeral work should be presented. Special reference was made to the "collective investigation of disease," a work which had received especial attention in Great Britain. The fields in which inquiries of this character might be extended are as broad as the domain of medicine. One of the most promising fields of labor for combined observation is in the *self* study of disease by medical men. By taking up some subject and studying it in this manner, limiting the inquiry to few questions, and to the profession in this vicinity, much good might result.

The bent of medical thought and teaching for the present is rather pathological and clinical, and he would not say a word to depreciate labor in these directions, but simply throw out the caution that we should not, in too close absorption in the study of local changes of tissue and their clinical manifestations, lose sight of those broader diathetic manifestations which will, from the same apparent cause, produce different diseases in different persons.

The President said that he considered it a part of his duty to continue the good work of the Society of prosecuting illegal practitioners of medicine.

COMMITTEES FOR THE ENSUING YEAR.

At the close of his address, THE PRESIDENT appointed the following committees:

Committee on Hygiene.—Dr. A. Jacobi, Chairman—Drs. E. H. Janes, W. T. Alexander, R. H. Derby, and R. Van Santvoord.

Committee on Ethics.—Dr. Laurence Johnson, Chair-

man—Drs. W. M. McLaury, J. L. Campbell, Ellsworth Eliot, and E. L. Partridge.

Committee on Prize Essays.—Dr. C. C. Lee, Chairman—Drs. R. F. Weir and T. A. McBride.

Auditing Committee.—Drs. P. A. Morrow and H. P. Farnham.

THE PRESIDENT also referred to the great loss to the profession caused by the death of J. Marion Sims, and appointed Dr. W. Gill Wylie to read a memoir at the meeting in January, 1884.

The paper for the evening was read by Dr. J. LEONARD CORNING,

ON CEREBRAL EXHAUSTION.

We know of an inadequacy of the functional capacity of the motor apparatus dependent upon mal-nutrition of the muscle itself. We are also cognizant of a similar state of things affecting the organ of thought. It is of this impairment—this exhaustion of the functional capacity of the thought mechanism—that I would speak this evening.

Under the designation "cerebral exhaustion" I propose to consider a group of clinical phenomena, the chief feature of which is a morbid limitation of the ratiocinative capacity of the individual consequent upon functional brain disease.

The manifestations of cerebral exhaustion are chiefly comprised under the following headings:

Psychical symptoms: 1, Morbid limitation of the ratiocinative processes; 2, Morbid emotional phenomena; 3, Derangements of memory; 4, Volitional impairment; 5, Evanescent mental confusion; 6, Disorders of sleep—morbid dreams; 7, Lack of mental concentrativeness.

Physical symptoms: 8, Ocular symptoms; 9, Acoustic symptoms; 10, Vaso-motor disturbances and cardiac derangements; 11, Local head pains.

Secondary symptoms, sometimes consecutive to or accompanying the primary exhaustion: 12, Insufficiency of voluntary muscular power; 13, Morbid fears; 14, Lachrymose condition in the male (wrongly designated hysterical); 15, Morbid sexual manifestations.

These were discussed in the order of their clinical occurrence.

DR. PUTZEL said that cerebral hyperæmia and anæmia were rarely found at autopsies, except as produced by some local organic disease, and therefore he could not receive the theory that circulatory disturbances are present in cerebral exhaustion. He also thought ophthalmologists would agree that the condition of the retina could not be called in to sustain the theory. Concerning treatment, he thought no drug had done more harm than bromide of potassium in the condition of neurasthenia. It may allay the symptoms for a while, but it aggravates the cases if continued for a long time. He believed that these factors should not be lost sight of in studying this condition: 1, Hereditary tendency, shown differently in different persons; 2, worry; and 3, general anæmia. Those cases arising from hereditary tendency he doubted if they could ever be cured permanently. He favored the use of arsenic especially.

DR. WEBSTER had examined the retina in several patients suffering from cerebral exhaustion, so called, and had failed to find any marked deviations from the normal.

DR. ROOSA substantially sustained Dr. Webster's experience.

DR. JACOB said the subject was interesting, not mainly because the brain is not well understood, but because the brain cannot be studied as a specialty. Persons suffering from quite a number of other diseases will suffer from cerebral exhaustion, and therefore the brain condition can be removed by the cure of the original affection. The condition might be one of hyperæmia or anæmia, but he thought it would not be correct to speak of disease of the brain the result of overwork or worry or any such cause. He supposed the speaker meant simply functional exhaustion.

DR. CORNING said he meant that the protoplasm of the cells was affected in some way not now known.

DR. JACOBI said that so long as we did not know what the character of the change in the protoplasm is, it should be called functional in character, and that view had a special influence on prognosis and treatment. He did not believe that from the condition of the external blood-vessels we could judge of the internal blood-vessels. On the other hand, hyperæmia might exist at autopsy and during life be the attendant of a general anæmia. He regarded cerebral exhaustion as a condition of disturbed nutrition, and therefore both local and general treatment might be beneficial. Dr. Jacobi favored the use of the galvanic current, arsenic, and digitalis.

DR. A. H. SMITH regarded faulty nutrition as the chief factor in these cases, but behind that there was probably a disturbance in the distribution of the blood from vasomotor influences. He also referred to the beneficial effects produced by digitalis.

DR. E. C. HARWOOD spoke of the good effects produced by rest, recreation, horseback exercise, fresh air, and life in Switzerland.

DR. GARRISH spoke of the importance of treating the general system and the avoidance of all exciting causes, such as the use of tobacco, etc.

DR. CORNING, in closing the discussion, said he regarded the cardiac trouble as secondary to the condition of the brain, and that treatment directed to the brain would relieve the cardiac symptoms. Of course, in studying these cases organic diseases must be eliminated, and he thought that hyperæmia and anæmia could be demonstrated better in the living subject than at the post-mortem table. With regard to digitalis, it was a remedy which he had used successfully and had recommended in a monograph published about one year ago.

THE PRESIDENT presented a certificate of Honorary Membership to Brevet Lieut.-Colonel Bennett A. Clements, Surgeon U. S. Army.

DR. JACOBI moved that a vote of thanks be extended to Dr. Webster for the faithful discharge of his duties as President. Unanimously carried.

DR. E. C. HARWOOD moved that the recommendations contained in the President's inaugural address be referred to the Comitia Minora to report some plan by which they can be carried out. Carried.

The Society then adjourned.

mind which becomes Christian men and women is that of humble recipients of scientific truth."

In reference to evolution, Mr. Le Gros Clark, F.R.S., said, "it must be admitted that evolution has no *present* scientific pretension which can be regarded as admirable, to include man, morally, mentally, or physically, in its vast and varied family. I might even venture further by saying that the early history of man, so far as yet revealed to us by science, might not unnaturally induce in some minds a distrust in a theory which is compelled to rest so much on surmise and possibilities. The failing proof *may* be furnished at some *future* day, and we may await patiently and fearlessly what that future shall unfold." This will suffice for a specimen of statements which were received with satisfaction by the Congress. I quote this speaker as one of our profession whose name will be almost as familiar on your side of the Atlantic as on ours, and I might supplement it by what Prof. Flower, equally well known to you, in his turn said. I refrain from citing the speeches of the clergy in a medical journal, but some of them were characterized by a firm grasp of science.

In other quarters there are indications that the doctrine of Darwin is losing some of its charms for scientists. Some tell us that they accept it as a step to something else. Others find its demands on their credence too great. Your readers know pretty well the opposition it has encountered by such men as St. J. Mivart, Virchow, Wharton Jones, F.R.S., and others. A further indication of uncertainty in scientific minds is afforded by the statements of Prof. Tyndall, who, in the *Popular Science Review*, says that "Evolution belongs to the dim twilight of conjecture. . . . Those who hold the doctrine are by no means ignorant of the uncertainty of their data, and they only yield to it a provisional assent. . . . Long antecedent to his advice I did exactly what Virchow recommends, showing myself as careful as he could be, not to claim for a scientific doctrine a certainty which did not belong to it. . . . I agree with him that the proofs of it are wanting. I hold with Virchow that the failures of proof are lamentable, that the doctrine of spontaneous generation is utterly discredited."

Nevertheless, at the British Association for the Advancement of Science, one of the chairmen spoke of the doctrine as "firmly established," a phrase more easily uttered than justified in the face of the most recent expressions of the most cautious scientists.

Referring to the British Association, I may remind you that next year this great scientific congress is to cross the Atlantic and meet at Montreal under the presidency of Professor Dawson, and this fact again reminds me of a meeting of which you may not have heard, as our newspapers seem to have largely neglected to report it. I allude to an afternoon meeting of members of the Association, convened during the late congress, for the purpose of devotion—in fact, a prayer-meeting called and conducted by scientists of eminence. Four out of six who signed the circular convening this meeting were Fellows of the Royal Society, and the attendance was much larger than might have been anticipated. Principal Dawson himself delivered a memorable address, Dr. Gladstone and Professor Hull took part in the proceedings, and many regard this meeting on the Sunday afternoon as one of the most interesting of the gatherings at Southport. Men of this stamp are, of course, above being scoffed at, and indeed, in this age, few if any of the leading scientists should be classed as scoffers. Most claim to be seekers after truth and the claim is freely admitted.

Dr. Maudsley has attained some repute as an alienist, and his writings have made him more widely known as a materialist of the materialists. His admirers call him "outspoken," others call him flippant, or self-satisfied, or conceited. A recent slip should suffice to moderate his conceit, as it will injure his reputation with scholars. In

Correspondence.

OUR LONDON LETTER.

(From our own Correspondent.)

ANOTHER HONOR TO THE PROFESSION—DR. ACLAND, F.R.S., AND NOW C.B.—MEDICAL MEN AT THE CHURCH CONGRESS—EVOLUTION—BRITISH ASSOCIATION FOR ADVANCEMENT OF SCIENCE—A PRAYER-MEETING OF SCIENTISTS—DR. MAUDSLEY'S LATE BLUNDER.

LONDON, November 10, 1883.

DR. ACLAND has received the—dignity (shall I call it?) of C.B. If a knighthood was lately declined this lesser distinction seems a very poor one to offer the Oxford Professor and President of the Medical Council. As a kind of titular head of the profession, surely he might have had something as much thought of as the titles so freely given by this ministry to brewers. Mr. Gladstone had better repair this blunder by promoting the doctor to the next grade—K.C.B.

If the Church Congress should follow the precedent set this year of inviting eminent scientists to make communications, the proceedings will probably attract more attention than hitherto. At the late meeting the subject was put before the Congress as perhaps few could have anticipated, a bishop observing that "the attitude of

proof of an argument he advanced to show that evolution was true, nay that alongside of it there has been going on a process of degeneration, and that this will in the end get the upper hand and rapidly undo all that has been done, he finds evidence *to satisfy him* that we are already on the way back to nothingness in the "egoistic hyperæsthesia" of this age.

Do your readers ask what that is? It is only our present condition as contrasted with the Homeric age. Then we are assured that there was "deep, calm, restrained, and massive feeling, fusing intelligence and activity into whole and universal unity." Brave words, these! and the contrast, the now—what of that? Only "howling displays of self-consciousness" and "shrill outcries of sentimentality" which constitute the "egoistic hyperæsthesia." In proof of this stupendous proposition the only evidence offered by Dr. Maudsley is a poem on the death of Achilles which he has mistaken for Homer, but which we learn was written from a present-day view, a couple of years ago. The author, the Rev. O. Ogle, probably little dreamed that his effusion would pass as the "Blind Bard's" within so short a period of its publication, and if Dr. Maudsley's speculations are generally as devoid of evidence as this, we may wait with equanimity the results of the process of de-evolution which he dates from Homer, and even bear calmly the "egoistic hyperæsthesia" which, according to his forebodings, will shortly transmute man into a much fiercer monkey than the one from which he dates his ancestry.

Army and Navy News.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from November 17 to November 24, 1883.

MOORE, JOHN, Lieutenant-Colonel. Relieved from duty as Medical Director Department of the Columbia. G. O. 29, Department of the Columbia, November 8, 1883.

BACHE, DALLAS, Major and Surgeon. Assigned to duty at Fort Adams, R. I. S. O. 215, par. 5, Department of the East, November 19, 1883.

BROOKE, JAMES, Major and Surgeon. Relieved from duty at Angel Island, Cal., and assigned to duty as Post Surgeon, Presidio of San Francisco, Cal. S. O. 162, par. 1, Department of California, November 14, 1883.

HORTON, SAMUEL M., Major and Surgeon. Leave of absence granted October 20, 1883, extended three months. S. O. 266, par. 7, A. G. O., November 20, 1883.

TOWN, F. L., Major and Surgeon. Until further orders, to perform the duties of Medical Director, Department of the Columbia. G. O. 29, Department of the Columbia, November 8, 1883.

WILLIAMS, JOHN W., Major and Surgeon. Granted leave of absence for one month, on surgeon's certificate of disability, with permission to leave the limits of the Department. S. O. 157, par. 5, Department of the Columbia, November 12, 1883.

APPEL, A. H., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Warren, Mass., and assigned to duty at Madison Barracks, N. Y. S. O. 217, par. 4, Department of the East, November 21, 1883.

COCHRAN, J. J., First Lieutenant and Assistant Surgeon. Assigned to duty at Fort Bayard, N. M. S. O. 236, par. 5, Department of the Missouri, November 15, 1883.

RICHARD, CHARLES, First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Adams, R. I. S. O. 216, par. 3, Department of the East, November 20, 1883.

WILSON, GEORGE F., First Lieutenant and Assistant Surgeon. To report in person to Lieutenant Schwatka, Third Cavalry, aide-de-camp, for temporary duty in con-

nection with the completion of report of recent expedition to Alaska. S. O. 156, par. 3, Department of the Columbia, November 9, 1883.

APPEL, D. M., Captain and Assistant Surgeon. Granted two months' leave of absence. S. O. 68, Division of the Atlantic, November 16, 1883.

MUNN, CURTIS E., Captain and Assistant Surgeon. Assigned to duty at Fort Warren, Mass. S. O. 216, par. 4, Department of the East, November 20, 1883.

WINNE, CHARLES K., Captain and Assistant Surgeon. Relieved from duty at Fort Winfield Scott, Cal., and assigned to duty as post surgeon Angel Island, Cal. S. O. 162, par. 1, Department of California, November 14, 1883.

Official List of Changes in the Medical Corps of the Navy, for the week ending November 24, 1883.

KENNEDY, STEPHEN D., Medical Inspector. Dismissed the service by sentence of a General Court Martial.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending November 27, 1883:

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
<i>Cases.</i>								
November 20, 1883.....	0	32	44	1	51	39	1	0
November 27, 1883.....	0	33	64	2	36	37	0	0
<i>Deaths.</i>								
November 20, 1883.....	0	13	9	1	6	22	0	0
November 27, 1883.....	0	12	7	2	4	16	0	0

THE NEW YORK CATTLE QUARANTINE.—The United States Government has bought forty acres of land at Garfield, N. J., having in view the establishment of a quarantine station to which all foreign cattle arriving in the port of New York are taken. If the animals, however, are found suffering from any fatal contagious disease, as lung plague, rinderpest, or aphthous fever, they must not be admitted to the regular quarantine, but quarantined elsewhere. The cattle seemingly free from all infectious diseases are taken to the Garfield grounds with great care, every precaution being taken to avoid any risks of spreading a disease. Only cattle arriving by the same ship may be quarantined in the same yard, and the rules require that all gates of yards shall be kept locked when cattle are entering or leaving the quarantine grounds. A veterinary inspector has general supervision and reports to the Treasury Cattle Commission the appearance of any contagious disease. As a further precaution the manure is quarantined for three months after the cattle have served their ninety days and then removed from the grounds.

THE USE OF CLEAN AIR IN THE COMPRESSED-AIR CHAMBER.—Dr. Arthur J. Wolff, of Hartford, Conn., writes: "I notice in THE RECORD of October 6th, an extract from a letter of Prof. J. Solis Cohen, of Philadelphia, which is certainly very unfair, to say the least. Does it become us to rest satisfied because our patient is breathing impure air in his environments, to force the same and dirtier air down his throat? Let the doctor well understand me before he shoots in his pseudo-overwhelming criticism. I claim from my observations on this matter, that the chamber, as at present used, concentrates all the matters contained in the air into a

small space; it removes all the living particles from currents (a very important consideration), supplies them with moisture and the necessary pabulum for their nutrition and increase; in other words, it makes contaminated air more contaminated. The limited area contains in it every favorable circumstance for the proper development and multiplication of any disease-germs contained in the atmospheric air, which, if used unsterilized from the consulting-room, will, after the lapse of a few hours, be found to contain a far greater number of microbes than could be formerly demonstrated by the microscope. Had the doctor thought a moment, he would not have condemned the sterilizing of the air, if for no other purpose than that of cleanliness. If his mode of reasoning is correct we may as well advocate the use of unclean instruments when we are going to operate on an unclean individual, because, forsooth, cleanliness around and about him 'is superfluous;' or because a patient is breathing infected air, and is in contact with septic matter, antiseptic precautions in the treatment of his wounds are superfluous. A reference to the doctor's very valuable work on 'Throat Affections,' will show the pathological importance to which attaches the inhalation of certain disease-germs, and yet he asserts that the use of absolutely clean air is unnecessary, because the individual is surrounded by and breathing in an impure atmosphere. Now, sir, I hold that there is a vast difference between breathing this air, and forcing the same down the throat and into the lungs of a patient suffering already with inflammatory trouble, and when, as I have found, the same is much dirtier than ordinary air, I am not surprised that the spray has often led to an increase of the throat disease. Let me ask Dr. Cohen if he has ever found strict precautions as regards cleanliness a 'superfluity?' and if he answers in the affirmative (as his letter would imply), we will then grant the justice of his criticism. If the use of clean air in the compressed air-chamber 'be superfluous,' we may as well cancel all the advances and improvements made by modern medical and surgical science in that direction as being also superfluous."

TYPHOID FEVER IN ALLEGHENY CITY.—Dr. D. N. Rankin gives, in the *Pittsburg Medical Journal* for October, 1883, an account of the origin of an epidemic of typhoid fever recently prevalent in Allegheny City. There were in all forty cases scattered through three different wards. The physicians were at first disposed to attribute the cause of the disease to foul emanations from dumping-grounds in the vicinity, but it was finally suggested that every family in which typhoid fever had occurred was supplied by the same milkman. When this fact was made known to the physician of the Board of Health of the city, he at once inspected the premises of the milkman, and found the following state of affairs: The dwelling and stable were on the side of a hill, the well from which the water for his family as well as for the cows was obtained being about fifty feet from the privy vault, which is higher up the hill than the well. The privy vault was full. There was at the time of the investigation, and had been for several weeks, a case of typhoid fever in the house. Examination of the well water showed that it was contaminated with organic matter of animal origin and many living organisms. There would seem to be little doubt, therefore, that the typhoid infection was spread by the milk.

SUCCESSFUL CASE OF CHLOROFORM NARCOSIS DURING SLEEP.—Dr. A. W. Hurd, house physician to the Alms-House Hospital, Blackwell's Island, sends the following: "The recent adverse testimony in the 'chloroform narcosis during sleep' question leads me to report a case under my observation. As one affirmative case has much more weight than a number of negative ones, I think this will prove of interest, especially as there can be no doubt of the completeness of the anæsthesia in this instance. October 5th, a man, seventy years of age, a coalheaver by occupation, was admitted to the hospital with severe con-

tusion of left forearm and elbow, and a subclavicular dislocation of humerus. He appeared partially demented, gave a very indefinite history of his injury, and resented vigorously any attempts either at examination or reduction. So violent was he that it was decided to induce anæsthesia during sleep if possible, and attempt reduction. About two hours after falling asleep in the evening, chloroform was administered on a handkerchief held about ten inches from his face at first. He breathed quietly, and made not the slightest sign of disturbance. The handkerchief was brought gradually nearer, and when he seemed fairly unconscious ether was substituted for the chloroform. The change did not disturb him, except to cause a slight alteration in the rhythm of his breathing for a moment. With the assistance of Drs. Herrick and Winstock the dislocation was then reduced, but with difficulty, the examination revealing the presence of numerous adhesions. The dislocation was evidently of older date than the contusion, while we thought it probable that they were both acquired at the same time. The manipulation required at least fifteen minutes, and rotation was resorted to, to break up the adhesions—the dislocation finally being reduced. The patient came out from the influence of the ether in about ten minutes. The completeness of the anæsthesia is unquestionable, as the manipulations were such as would be very painful to a conscious person. The ease with which the anæsthesia was obtained, and the thoroughness of the test of its genuineness seem worthy of note as opposed to the number of unsuccessful cases recently published, accompanied by a criticism that the tests ordinarily employed were insufficient."

THE LILY OF THE VALLEY IN HOMŒOPATHY.—"Some Western homœopaths," says *THE MEDICAL RECORD*, "have got hold of *convallaria*, and having read all that scientific medicine has to say about it, are quietly appropriating the drug themselves." The first knowledge we obtained of this drug was from Dr. John F. Gray, who used it for many years in heart troubles, and we believe was the first to introduce it to the profession. The new school has a habit of reading all that scientific medicine has to say of a drug, and quietly appropriating the facts. We are glad that some of the old school are following their example.—*New York Medical Times*.

CONCERNING CRAMMING FOR EXAMINATION.—A correspondent from the Navy writes: "The question of 'cramming' and frequent examinations which have occupied the attention of Dr. Shufeldt, Professor Coues, and others, excites no little interest among our English cousins. The testimony of Mr. Walter Wren, 'the eminent crammer,' and of numerous correspondents of the *Times*, has shown up these matters in a true light, and it is evident that we have not a monopoly of 'superficial education.' There is a very general belief in England that there is too much 'cramming' in the public and private schools, and at the universities; and that knowledge will be found in inverse ratio to the cost of education. As with us, too much is attempted in too short a time, and a mere 'smattering' is the result. This is the history of our private and public schools, Annapolis and West Point. A writer in the *London Times* states that he crammed his son on subjects of which he knew literally nothing, 'and so stuffed him that he passed easily' a rigorous examination. He tried him again shortly after, and found 'his mind had returned to its original vacuity.' In the United States Navy, examinations are carried to a ridiculous extent, one for each grade (except in the engineer corps, where it would appear the most important) and the result by no means justifies the loss of time, vexation, and expense incurred. The profession of physic no doubt needs students better prepared academically, and professional examination made by or under the supervision of a supreme medical council. Diplomas and licences should be granted by this body, and not by interested college faculties. In Government

departments a very *rigorous* entrance examination should be required, and a second examination at the end of five or ten years may be needed to determine the advance or improvement of an officer in his professional studies, or better still, a post-graduate or polyclinical course should be insisted upon; but as a man is 'either a fool or a physician at forty,' it is absurd to examine men at fifty or sixty years of age, to test their *practical* skill or ability."

DOCTORS ON MARRIAGE.—Dr. Clifford Allbutt, in a recent address, says: "In matters of wider bearing—in the larger social and political questions—we shall do well, as Bacon says, 'not to usurp a kind of dictature in sciences, nor with over-confidence to pass censure upon matters in doubt, nor to give way to peremptory fits of asseveration.' All professions, not one only, tend to put on the priesthood, if not checked by conflicting authority; to give themselves airs, in short. A doctor's one idea being very properly a sound body, he proclaims that, if he were king, no members of a family tainted with consumption or insanity should marry; as if the frail tenements which held the spirits of Keats, or of Elia, or Arthur Hallam, or of W. K. Clifford, bore not freights more precious than a wilderness of cricketers. To come nearer home: Addison was one of the ablest teachers the art of medicine ever knew; now Addison was bred of insane blood, and died by his own hand. Who are we who pretend that we can lose such lives as these, or who deny that their genius drew any quality from the instability of their blood? Our answer to questions of this kind is to point out the dangers clearly, and wherein they lie, or increase; but not to claim alone to bind or loosen, nor to measure all things with our own foot-rule. Even in lower matters, where we see more clearly, as in sanitary questions, we cannot drag people blindfold."

A FRENCH SURGEON'S VIEWS OF AMERICAN WOMEN.—M. Poncet, a surgeon of Lyons, France, has been travelling in this country and has recorded some of his impressions in the feuilleton of the *Lyon Médicale*. His observations upon the anatomy of American women possess some novelty. He is quoted by the *Boston Medical and Surgical Journal* as follows: M. Poncet "is struck by a certain similarity of conformation between the women of the 'New World' and those of 'blonde Albion,' both are deficient in '*pectus*,' the mammary glands are but little developed, or there is at least a want of harmony between the size of those organs and the general figure. The upper part of the body, apart from the head, which is often very expressive, sometimes extremely beautiful, is disappointing in volume. The pelvis and the lower limbs, on the other hand, he finds well developed. This disproportion frequently struck the writer at the hospitals. He concludes that the German transplanted to the United States will become less productive, and in this respect more and more like the native American."

We would like to ask Dr. Poncet how about the *pectus* of the French women? According to statistics, the French birth-rate is the lowest of any nation. Therefore, if the French women have a gratifying mammary development, it is not a result or evidence of fecundity.

THE USE OF CARBOLIZED SAWDUST as an antiseptic surgical dressing is advocated by Mr. H. P. Symonds in *The Lancet*. He says: "One of the drawbacks of the usual antiseptic dressing is the rapidity with which the discharges come through on the first day or two after operation, often necessitating the redressing of the case within a few hours. To prevent this, and yet not to interfere with the aseptic condition of the wound is a distinct advantage both to the patient and the surgeon. The material I have used recently in a considerable number of cases is coarse sawdust, soaked in (one in ten) solution of absolute phenol and spirits of wine, then allowed to dry slightly so that the spirit may evaporate, leaving the sawdust charged with carbolic acid. When

used it is enclosed in a bag made of several layers of gauze, and applied outside of the deep dressing, the usual external dressing being put over it. The sawdust thus takes the place of the padding of loose gauze which is generally used. Its absorbent power is very great, and it has the additional advantage of keeping up an equable pressure on the divided tissues. Fourteen ounces of sawdust will readily absorb about one pint of fluid. He reports five cases, taken without any selection, in all of which complete primary union took place without any formation of pus. The three points in its favor are its powerful antiseptic qualities when saturated with carbolic acid, its great absorbent power, and its adaptability to any surface. The sawdust should be coarse, as it passes through the gauze when very fine and irritates the skin."

THE STUDY OF INSANITY AS PART OF THE MEDICAL CURRICULUM.—The obligation of medical men to be examined in the treatment of insanity has been a subject of discussion in the German Legislature, and the question has been decided in favor of the omission of the proposed test. Certain sections of the medical press in Germany have, however, expressed the opinion that the connection between mental and corporeal disease is in some instances so close that the physician would gain by having at his command a special knowledge of the subject in question. The hope is expressed, says *The Lancet*, that in the interest of their professional skill young doctors will not avail themselves of the step which the government has taken, but will devote attention to mental diseases and their treatment.

M. PONCET ON THE AMERICAN METHOD OF LIVING.—Dr. Poncet, of Lyons, France, gives the following Gallic account of the way we live: "If there is any truth in the proverb, 'Tell me what you eat, and I will tell you what you are,' it is amply illustrated in the New World. The American does not eat, he simply fills himself; his sole desire is to satisfy hunger, and if he can secure quantity, quality is of little importance; hence one frequently sees him ingest a lot of food standing up, or scarcely seated, at a counter. There are fixed hours between which meals may be had, and food must be taken at those times whether one be hungry or not. A despotic, all-powerful public opinion, which no one dares defy, decrees the hours for eating. The meals are always begun with a square block of rancid butter, having an odor of margarine. A pause of fifteen to twenty minutes gives time to attempt the digestion of this compound, and then you find yourself surrounded by a variety of little dishes which you expressed an intention to eat. It matters not that they become cold, for do you not see around you 'des misses, des ladies, des gentlemens' eating watermelon with chicken, and currant jelly with cutlets and salad! Behind your chair is one negro who fans you, and another who puts ice in your glass." The writer apparently was not struck with the number of our religions, but it does not escape him that we have but one sauce, and that like glue, by which otherwise good meats are ruined. Our eggs have a queer, stale, animal flavor, which is supposed to result from the hens being fed upon meat that they may lay more. Corn is a favorite article of food, and though eaten in various ways, is most often boiled on the cob. Three or four of these cylinders are not too much for a lover of this cereal, who will gnaw off the grains with his teeth, and presently leave nothing but "*la carcasse*."

A PEOPLE WITHOUT CONSUMPTION.—A paper was read recently before the Tennessee Medical Society with the title, "A People without Consumption, and some Account of their Country." The country in question is the Cumberland plateau. The writer, Dr. Wright, has practised in the region throughout a generation, and in his assertion of fact touching the entire absence of consumption he is supported by the testimony of about twenty other physicians of standing.—*Medical and Surgical Reporter*.

Whole No. 683

CEREBRO-SPINAL FEVER.

By J. LEWIS SMITH, M.D.,

CLINICAL PROFESSOR OF DISEASES OF CHILDREN, BELLEVUE HOSPITAL MEDICAL COLLEGE.

(Continued from p. 590.)

CASES seen by the writer, chiefly during the last five years. Those in the epidemic of 1872 not in the list. The symptoms commonly present, as vomiting, headache, neuralgic pain in trunk and limbs, retraction of head, rigidity of posterior cervical and other muscles, the temperature and pulse, though recorded in my notes, are omitted in the table, unless they presented unusual features. The duration is reckoned, in those who recovered, to the time when they could stand or walk, though with difficulty.

No.	Sex.	Age.	Mode of commencement.	Unusual or noteworthy symptoms.	Duration.	Result.
1	Male.	10 months.	Sudden; no prodromes.	Eclampsia on first days; retraction of head and muscular rigidity 4 weeks.	6 months.	Recovery.
2	Male.	3 years.	" " "	Internal strabismus of right eye; dangerously sick 7 weeks.	9 weeks.	Recovered, except strabismus which is permanent.
3	Female.	2 years.	" " "	Eclampsia; coma.	9 days.	Died.
4	Male.	30 years.	" " "	Delirium; coma.	5 days.	Died.
5	Male.	22 years.	" " "	Herpes around mouth.	8 weeks.	Recovered.
6	Female.	4 years.	" " "	Chilliness; great pallor at first; delirium, great restlessness, convulsions, and coma.	6 days.	Died.
7	Male.	2 years, 2 months.	" " "	Vomiting at intervals for 7 weeks; head so retracted that finger could with difficulty be pressed to nucha; had constipation and strabismus; usually lay with eyes shut and screamed when disturbed; feet and legs usually cool from the second to the tenth week; much emaciated.	Temporary abatement of symptoms in the third week so that he played for a few hours, followed by a full relapse. Began to stand and walk with a tottering gait on the sixteenth week.	Recovered.
8	Male.	20 months.	Rather languid on previous day, but played.	Began with clonic convulsions and high febrile movement at night; convulsions at 5 A.M., 12 M., and 3 P.M.; appeared dying, and deglutition impossible on the first day; deglutition again impossible during the three days before death.	25 days.	Died comatose.
9	Female.	3 years.	Vomited and seemed sick after a slight punishment on June 11, 1882, on the 12th was better, had some appetite and went out. On the 13th cerebro-spinal fever began with a temperature of 103°.	The muscular rigidity became less after the twelfth day; lost speech on the second day, and was unable to articulate for 2½ months; strabismus; <i>tache cerebrale</i> .	Was in bed 2½ months, unable to stand or walk; when recovering and fully conscious, made frequent attempts to speak, but without any sound. Finally articulated slowly, and the easiest monosyllables.	Recovered, but after 1 year speech slow and lisping; gait unsteady and hands tremulous; easily fatigued; is very sensitive and cries often.
10	Male.	28 years.	Ate heartily at 12 M. on April 23, 1883, and at 1 P.M. had a chill; vomited severely, and had intense headache; minute red points in face after vomiting, from capillary extravasations. On April 24th, vomiting and headache ceased and he remained well till the 26th. Went to Brooklyn on the 25th. On the 26th pains commenced in head, back, and limbs, with febrile movement.	Had general convulsions on April 30th, lasting 10 or 15 minutes; could walk in the sickness, but with tottering gait, and always had some appetite.	Left the house in five weeks, but a glass of beer or other stimulant caused renewal of headache, which during the sickness had been oftenest in the occiput, though it was frequent in other parts of the head.	Recovered.
11	Male.	6 years.	Previously well and the day before very cheerful.	Head retracted two weeks.	Began to walk in the fourth week, and progressively improved.	Recovered.
12	Male.	3 years, 8 months.	Was punished, though not severely, and soon after cerebro-spinal fever began with febrile movement and convulsions.	Opisthotonos, and retraction of head 10 weeks; greatly emaciated; could not speak for three months; apparently could not hear at first or was too unconscious to notice sounds.	3 to 3½ months.	Recovered.
13	Male.	10 years.	Sudden, in school.	Muscular rigidity with retraction of head; great emaciation; ulceration of cornea.	9½ weeks.	Recovered.
14	Female.	9 years.	Sudden; no premonition.	Vomiting; marked opisthotonos.	10 weeks, but fainted on slight exertion for months afterward.	Recovered.
15	Female.	11 months.	" " "	Eclampsia; apparently did not notice objects during the first month.	9 weeks.	Recovered.
16	Female.	12 years.	" " "	Great emaciation; had occasional neuralgic pains for eighteen months after convalescence.	6 weeks.	Recovered.

No.	Sex.	Age.	Mode of commencement.	Unusual or noteworthy symptoms.	Duration.	Result.
17		10 months.	Sudden; no premonition.	Inability to swallow; drinks passing into the larynx; abundant secretion on faucial surface without redness.	2 days.	Died.
18	Male.	2 years.		No vomiting.	3 days.	Died.
19	Male.	6 months.	Bottle-fed; had been fretful, but immediately before disease began seemed well.	Had convulsions, the mother says as many as fifty.	10 days.	Died.
20	Male.	11 years, 5 months.	Had diarrhoea two days previously, but otherwise in usual health; attended school on day when sickness began, and returned home in the afternoon with a chill with which disease began.	Eclampsia on the fourth day; pulse 169, temperature 105°; pupils widely dilated and not responsive to light.	4 days.	Died.
21	Female.	2 years, 3 months.	Sudden.	Had paresis of all the limbs; when convalescing, inability to support the head and shoulders erect; rests them often upon the sofa or the mother's lap.	Began to stand in 4 weeks.	Recovered.
22	Male.	10 months.	Sudden.	Left pupil larger than the right; partial paralysis of left leg, complete of right.		
23	Female.	12 years.	Came from school crying with pain in top of head, in knees and calves of legs and with dizziness.	On second day intense frontal headache; left pupil larger than the right, numerous spots over entire body; mild conjunctivitis of right eye; third, right pupil larger than left, the reverse of yesterday; fourth day, dysphagia, left pupil much contracted, right pupil dilated; eighth day, right eye hyperæmic, as if from general inflammation; ninth, delirious; tenth, sees indistinctly with right eye, and objects yellow. Improved for a time and then became worse, the mother thinks from imprudence in her diet; right eye totally destroyed and its parts indistinguishable; no headache in last five days of life.	4½ weeks.	Died.
24	Male.	10 months.	Began suddenly with vomiting.	Eclampsia in second week; very fretful; eyelids usually closed; when aroused only partly raises upper eyelids; oscillation of pupils; finally no response to light and total blindness, although the appearance of the eyes was good; fingers firmly flexed at times; after abatement of the fever almost constant choreic movements of arms except in sleep. Four months after disease began, temperature 99¼°, pulse 136; eyes prominent and bright, though sightless till death.	Never able to stand but lived 10 months.	Died of diphtheria at age of 20 months.
25	Male.	4½ years.		Head retracted 4½ months, and patient in pain whenever moved during most of this time; greatly emaciated and prostrated.	Was in bed, unable to stand, 5½ months.	Recovered fully.
26	Female.	23 years.	Sudden with great headache.	Symptoms severe from the first; soon lost consciousness; removed to hospital on the sixth day.	11 days.	Died in coma.
27	Female.	4½ years.	Gradual.	No retraction of head; vomited, but not at first.	4 weeks.	Recovered, but with diverging strabismus & imperfection of sight.
28	Male.	4 years.	Sudden.	Pupils widely dilated, insensible.	1 week.	Died.
29	Male.	16 months.	Sudden.	Had pneumonia of the right lung, beginning on the third day with rise of temperature to 103½°.		Recovered.
30	Male.	7 months.	Sudden.	Frequent attacks of eclampsia during first week, unilateral, and usually short. Twice they occurred on the left side, but at other times on the right side; eclampsia followed by paralysis of right extremities and left side of face, it gradually passed off; right pupil larger than left; choreic movement of eyes; strabismus; in the second month temperature sub-normal.		Recovered with loss of sight; and perhaps blunted intelligence.
31	Male.	11 months.	Diarrhoea previously.	Eclampsia nearly constant for 24 hours; during the first four days pulse scarcely appreciable; inability to swallow; total unconsciousness; case apparently hopeless and near death; temperature, 105° to 106°; pupils did not respond; gradually improved after the fourth day.	Taken sick upon the shipping in Hudson River; removed to Jersey City on the eleventh day and lost sight of.	Probable recovery.
32	Male.	5 years, 1 month.	Sudden.	A chill followed by eclampsia on the first day; highest temperature, 106°, was on the first day; moaning and restlessness in the commencement. Great emaciation when a few weeks sick.	At 8 weeks could sit in bed; could stand a few weeks later.	Complete recovery.
33	Male.	10 weeks.		Had eclampsia; fretful; constipation with vomiting; temperature, 100°; head retracted.	9 days.	Died; autopsy.
34	Female; mulatto (Infant Asylum).	23 years.	Delivered of a healthy child August 6, 1881; convalesced satisfactorily; sickened with cerebro-spinal fever August 30th.	Intense headache; delirium, coma, strabismus; paralysis of right side of face.	3 days.	Died.

No.	Sex.	Age.	Mode of commencement.	Unusual or noteworthy symptoms.	Duration.	Result.
35	Male.	32 years.	Had typhoid fever three months previously; cerebro-spinal fever began suddenly after much mental excitement and worryment.	No elevation of temperature in first and second days; great pain in lower part of sacrum.	13 days.	Died.
36	Male.	9 years, 7 months.	Taken sick in school.	Eclampsia four days in the beginning; semi-coma in first weeks of disease; full consciousness and return of appetite in last part of sickness; great emaciation. Through negligence in nursing had three large bed-sores, extending to the bones, and suppurating abundantly.	18 weeks.	Died apparently from the bed-sores, one over the sacrum and one over each hip.

Pulse.—This is usually accelerated, and the more severe and dangerous the attack, the more rapid the heart's action, except occasionally in the comatose state, when probably, in consequence of compression of the brain from an abundant exudation, the pulse may be subnormal. Thus, in one of my patients, an adult, the pulse fell to 40 per minute, and in two others between 60 and 70 per minute. With the exception of these three patients, the pulse in all cases which I have observed, so far as I recollect, has varied from the normal number of beats per minute to such frequency that it was difficult to count it. As death draws near the pulse ordinarily becomes more frequent and feeble. Intermissions in the pulse do not seem to be as common as in other forms of meningitis, but marked variations in its frequency during different hours of the day, and on consecutive days, is a conspicuous symptom. Thus, in a case which was fatal in the fifth week, consecutive enumerations of the pulse, in the acute stage, were as follows, 128, 120, 88, 130, 84, 112.

Temperature.—Some of the older writers, before the days of clinical thermometry, stated that the temperature is not increased. North remarked as follows: "Cases occur, it is true, in which the temperature is increased above the normal standard, but these are rare," and Foot and Gallop make similar statements. Some recent writers have held the same opinion. Thus Lidell wrote as follows in a treatise bearing the date of 1873: ". . . Febrile symptoms do not necessarily belong to epidemic cerebro-spinal meningitis, as a substantive disease, for it may, and not infrequently does occur, without exhibiting any such symptoms." We would naturally expect that meningitis, accompanied as it is by active congestion of the brain and spinal cord, would produce more or less fever, and in eighty-six cases, which I have examined by the thermometer, I have found elevation of temperature in every case during the acute stage, except in the beginning of the attack in two instances. In a young man, aged twenty-eight years, who had severe headache and seemed seriously sick, the thermometer under the tongue showed no rise of temperature on the first and second days, but on the third day it was at 100°, and it remained elevated till his death, on the thirteenth day. The second case was that of a young woman whom I saw in consultation, and who at the time of my visit had decided febrile movement, but who, like the young man, had no rise of temperature on the first and second days, according to the careful observations of the attending physician. In the eighty-six cases which I have examined, the heat of the surface occasionally did not seem above normal to the touch, and now and then the thermometer, applied in the axilla or groin, did not indicate fever, but the rectal temperature was always elevated above that of health after the disease was fully established. The temperature fluctuated from day to day, and in different hours of the same day, but there was no exception after the second day to the rule, that it is supra-normal during the active stage of the malady. Sometimes the elevation of temperature was slight, as in a female patient, forty-seven years of age, whom I was allowed to examine with the family physician. The thermometer showed no elevation of temperature when it

was placed in the mouth and axilla, but on introducing it into the rectum it rose to 99½°.

The highest temperature which I have thus far observed, was 107½°, in a child aged two years. This was in the commencement of the attack. Subsequently it fell a little, but rose again on the third day to 107°, when she died. In two other cases the temperature was 106° on the first day, and it did not afterward reach so high an elevation. One of these died on the ninth day, and the other in the ninth week. The next highest temperature was 105¼°, also on the first day, in an infant aged eight months, who died on the ninth day. The first and last of these cases occurred in an old wooden tenement-house in the suburbs of the city, and upon an elevated outcropping of rock. The highest temperature in any case in New York City which has come to my notice, was observed in a male patient aged twenty-eight years, who had active delirium and died on the fifth day in Roosevelt Hospital. The temperature on the last day, taken four times, was as follows, 102½°, 106¾°, and when the pulse had become imperceptible, 109° and 107¾°. Wunderlich has recorded a temperature of 110° in one or two cases, but so great an elevation must be very rare, and is, of course, prognostic of an unfavorable ending.

The external temperature undergoes still greater fluctuations than the internal, rising above and falling below the normal standard several times in the course of the same day. Similar fluctuations occur in other forms of meningitis, but they are, according to my experience, less pronounced than in cerebro-spinal fever, especially as I observed them in the epidemic of 1872. Perhaps since that epidemic they have been less marked in the cases occurring in this city. The more grave the attack in those not comatose, the greater these variations. The following is a common example, in a patient aged two years. Without any notable change in other symptoms, the internal temperature varied from 101° to 104½° as the extremes, while that of the fingers and hands at the first examination was 99½°, at the second 90°, at the third 103°, and at the fourth 83°. Hence at the third examination the temperature of the extremities had risen 13°, so as nearly to equal that of the blood, and at the fourth examination it had fallen 20°. The patient recovered. These great and sudden variations in the pulse, and the internal and external temperature, have considerable diagnostic value in obscure and doubtful cases.

Respiratory system.—This system is not notably involved in ordinary cases. Intermittent, sighing, or irregular respiration appears to be less frequent than in ordinary meningitis, but it does occur. In most patients the respiration is quiet, but somewhat accelerated, and without any marked disturbance in its rhythm. In thirty-one observations in children who had no complication, I found the average respirations 42 per minute, while the average pulse was 137. Therefore the respiration, as compared with the pulse, was proportionately more frequent than in health, due perhaps to the fact that certain muscles concerned in respiration, as the abdominal, are embarrassed in their movements by tonic contraction.

Various observers, in different epidemics, have recorded an unusual prevalence of croupous pneumonia occurring

simultaneously with the cerebro-spinal fever. Bascome in his history of epidemics stated that "epidemic encephalitis and malignant pneumonias prevailed in Germany in the sixteenth century" (Webber). Webber in his prize essay describes a variety of cerebro-spinal fever, which he designates pneumonic, in which the cerebro-spinal axis is involved but slightly or not at all, and the brunt of the disease falls upon the respiratory organs. According to him, in certain epidemics the pneumonic form has been common and in others infrequent.

In New York City, during the epidemic of cerebro-spinal fever in 1872, pneumonia was also unusually prevalent, affecting many old as well as young people. According to the statistics of the New York Board of Health, seventeen hundred and seven deaths from diseases of the respiratory organs, exclusive of phthisis, occurred during the four months from February 1 to June 1, 1872, when the epidemic of cerebro-spinal fever was at its height, and only thirteen hundred and thirty-six deaths occurred from the same diseases during the remaining eight months of the year; and as phthisis is excluded, the only other disease of the respiratory system besides pneumonia, which causes a large mortality is membranous croup, which did not seem to be unusually prevalent during those four months. It is therefore probable, though not distinctly stated in the annual report of the Health Board for that year, that the great mortality from diseases of the respiratory organs, during that part of 1872 when cerebro-spinal fever was epidemic, was chiefly from pneumonia, and, according to my observations, many cases of pneumonia during that period presented symptoms of greater gravity than usually accompany this form of inflammation. The patients were greatly prostrated from the first, and in some of them febrile movement, muscular pains, restlessness, or delirium preceded for hours or even days the pneumonic symptoms, affording evidence that the lung disease occurred under certain unusual circumstances or conditions which modified its character. It is not improbable therefore that Webber's view is correct, that there are occasional cases of cerebro-spinal meningitis with pneumonia as one of its local manifestations. In the New York epidemic of 1872 a prominent citizen had a severe attack of what was supposed to be cerebro-spinal fever, one of his medical advisers being known throughout the country for his ability in diagnosis. On the sixth day the cerebro-spinal symptoms considerably abated, pneumonia appeared, and subsequently the prominent symptoms were referable to the lungs. He slowly recovered.

Cutaneous surface.—The features may be pallid, of normal appearance, or flushed in the first days of the disease, but in advanced cases they are pallid, as is the skin generally. A circumscribed patch of deep congestion often appears, as in sporadic meningitis, upon some part of them, as the forehead, cheek, or an ear, and after a short time disappears. The hyperæmic streak, the *tache cérébrale* of Trousseau, produced by drawing the finger firmly across the surface, also appears as in other forms of meningitis, if the temperature of the surface be not too much reduced.

The following are the abnormal appearances of the skin most frequently observed: 1. Papilliform elevations, the so-called goose-skin, due to contraction of the muscular fibres of the corium. This is not uncommon in the first weeks. 2. A dusky mottling, also common in the first and second weeks in grave cases, and most marked where the temperature is reduced. 3. Numerous minute red points over a large part of the surface, bluish spots a few lines in diameter, due to extravasation of blood under the cuticle, resembling bruises in appearance, and large patches of the same color, an inch or more in diameter, less common than the others, of irregular shape as well as size, and usually not more than two or three upon a patient. These last resemble bruises, and they may sometimes be such, received during the times of restlessness; but ordinarily extravasations of this kind result

entirely from the altered state of the blood. In New York, in the epidemic of 1872, they were common, but since this epidemic, in the thirty-six cases which I have observed, I have rarely seen either the reddish points or the extravasations of blood. They were probably common in the epidemics in the first part of this century in this country, since the disease was designated by the name spotted fever by the American physicians who wrote upon it at that time. That they are unusual in the European epidemics at the present time, we infer from the fact that Von Ziemssen expresses surprise that the disease should ever have been designated in America by such a title. 4. Herpes. This is common. It sometimes occurs as early as the second or third day, but in other instances not till toward the close of the first week or in the second. The number of herpetic eruptions varies from six or eight to clusters as large or larger than the hand. This cutaneous disease evidently has a nervous origin, the vesicles occurring in most instances on those parts of the surface which are supplied by branches of the fifth pair of nerves. Its most common seat is upon the lips, but occasionally it appears upon the cheek, upon and around the ears, and upon the scalp. Erythema and roseola fugitive skin eruptions occasionally appear, and in one instance in my practice erysipelas occurred. During the first days the skin is apt to be dry; afterward perspirations are not unusual, and free perspirations sometimes occur, especially about the head, face, and neck.

Urinary organs.—In other forms of meningitis it is well known that the quantity of urine excreted is apt to be diminished, but in this disease it is usually normal, and it may be more than normal. Polyuria has been noticed in different cases by various observers. Mosler observed a boy aged seven years, who had an excessive secretion of urine, which dated back to an attack of cerebro-spinal fever in his third year. The polyuria is probably due to injury of the nervous centre, since it is established by physiological experiment that irritation of the central end of the vagus, of certain parts of the cerebellum, and of the walls of the fourth ventricle, sometimes produces this effect. The urine occasionally contains a moderate amount of albumen, and in exceptional instances cylindrical casts and blood-corpuscles.

Arthritic inflammation, apparently of a rheumatic character, has been occasionally observed. It is commonly slight, producing merely an œdematous appearance around one or more joints. Thus in one case which came under my notice, and which was subsequently fatal, the parents, who were poor, and were therefore without medical advice till the case was somewhat advanced, had already diagnosticated rheumatism on account of the puffiness which they had noticed around one of the wrists.

The special senses.—Taste and smell are rarely affected, so far as known, but it is possible that they are sometimes perverted, or even temporarily lost, during the time of greatest stupor. In one case, which I saw, the sense of smell was entirely lost in one nostril, and I do not know whether it was ever fully restored.

The affections of the eye and ear are important and of frequent occurrence. Strabismus is common. It may occur at any period of the fever, continuing a few hours or several days, and it may appear and disappear several times before convalescence is established; occasionally it continues several weeks, after which the parallelism of the eyes is gradually and fully restored. In other instances it is permanent. Thus in a boy of five years, whom I last saw three months after convalescence, there was still convergent strabismus of the right eye, and double vision; and in a boy of three years, convergent strabismus of the right eye remained when I examined him twelve months after the occurrence of the fever.

Changes in the pupils are among the first and most noticeable of the initial symptoms, as I have already stated in describing the mode of commencement. These

are dilatation, less frequently contraction, oscillation, inequality of size, feeble response to light, etc. Most patients present one or more of these abnormalities of the pupils, and they continue during the first and second weeks, and gradually abate, if the course of the disease be favorable. Inflammatory hyperæmia of the conjunctiva often occurs. It begins early, and now and then the conjunctivitis is so intense that considerable tumefaction of the lids results, with a free muco-purulent secretion. The false diagnosis has indeed been made of purulent ophthalmia, in cases in which this affection of the lids was early and severe. But such intense inflammation is quite exceptional. More frequently there is a uniform diffused redness of the conjunctiva, not so dusky as in typhus, and the injected vessels cannot be so readily distinguished as in that disease.

In certain cases almost the whole eye (all indeed of the important constituents) becomes inflamed; the media grow cloudy, the iris discolored, and the pupils uneven and filled up with fibrinous exudation. The deep structures of the eye cannot, therefore, be readily explored by the ophthalmoscope, but they are observed to be adherent to each other, and covered by inflammatory exudation. They present a dusky red, or even a dark color, when the inflammation is recent. Exceptionally the cornea ulcerates and the eye bursts, with the loss of more or less of the liquids, and shrinking of the eye. "But ordinarily no ulceration occurs, and, as the patient convalesces, the œdema of the lids, hyperæmia of the conjunctiva, the cloudiness of the cornea and of the humors, gradually abate, and the exudation in the pupils is absorbed. The iris bulges forward, and the deep tissues of the eye, viewed through the vitreous humor, which before had a dusky red color from hyperæmia, now present a dull white color. The lens itself, at first transparent, after awhile becomes cataractous. Sight is lost totally and forever. This form of ophthalmia is sometimes rapidly developed, as in the following example:

On July 5, 1873, I was called to a boy, five years of age, who had reached the tenth day of cerebro-spinal fever without apparently any affection of the eyes, as both presented the normal appearance. On the following day the left eye was red and swollen from the inflammation and chemosis, so that the lids could not be closed, and the media were cloudy. Death occurred on the same day.

If the patient live the volume of the eye diminishes, as the inflammation abates, to less than the normal size, even when there has been no rupture, and escape of the fluids, and divergent strabismus is apt to occur. Professor Knapp, whose description of the eye I have for the most part followed, says: "The nature of the eye affection is a purulent choroiditis, probably metastatic." Fortunately so general and destructive an inflammation of the eye as has been described above is comparatively rare. On the other hand, conjunctivitis of greater or less severity, and hyperæmia of the optic disc, consequent upon the brain disease, are not unusual, but they subside, leaving the function of the organ unimpaired. "In some cases incurable blindness is noticed under the ophthalmoscopic picture of optic-nerve atrophy, probably the sequence of choked disc" (Knapp).

Inflammation of the middle ear, of a mild grade, and subsiding without impairment of hearing, is common. The membrana tympani, during its continuance, presents a dull-yellowish, and in places a reddish, hue. Occasionally a more severe otitis media occurs, ending in suppuration, perforation of the membrana tympani, and otorrhœa, which ceases after a variable time. But otitis media is not the most severe of the affections of the organs of hearing. Certain patients lose their hearing entirely and never regain it, and that, too, with little otalgia, otorrhœa, or other local symptoms by which so grave a result can be prognosticated. This loss of hearing does not occur at the same period of the disease in all cases. Some of those who become deaf are able

to hear as they emerge from the stupor of the disease, but lose this function during convalescence, while the majority are observed to be deaf as soon as the stupor abates and full consciousness returns.

Two important facts have been observed in reference to the loss of hearing in these patients—to wit, it is bilateral and complete. When first observed it is in some, as stated above, complete, but in others partial, and when partial it gradually increases till after some days or weeks, when it becomes complete. I have the records of ten cases of this loss of hearing, most of them occurring in my own practice in the epidemic of 1872, but a few of them detailed to me by the physicians who observed them in the same epidemic. According to these statistics about one in every ten patients became deaf, but in the milder form of cerebro-spinal meningitis which has prevailed since 1872, the proportionate number thus affected has been less among my patients, and the same may be said in reference to the loss of sight. One of the ten cases was a young lady, but the rest were children under the age of ten years. Professor Knapp has examined thirty-one cases. "In all," says he, "the deafness was bilateral, and with two exceptions of faint perception of sound, complete. Among the twenty-nine cases of total deafness, there is only one who seemed to give some evidence of hearing afterward." The same author has recently informed me that further experience has confirmed his previous statement, that while the blindness produced by cerebro-spinal fever is in the majority of cases monolateral, only one case had come to his notice in which the deafness was on one side only.

One theory attributes the loss of hearing to inflammatory lesions either at the centre of audition, within the brain, or in the course of the auditory nerves before they enter the auditory foramina. Thus Stillé says: "This symptom appears to depend chiefly upon the pressure of the plastic exudation in which the nerves are embedded." The other theory attributes the loss of hearing to inflammatory disease of the ear, and especially of the labyrinth. Dr. Sanderson, who is an advocate of the latter theory, remarks as follows: "As regards the nature of the affection, there appears to be good reason for believing that, like the blindness observed under similar circumstances, and sometimes in the same cases, it is dependent on inflammatory changes in the organ of hearing itself. Dr. Klebs was kind enough to show me, in the pathological museum of the Charité at Berlin, a preparation of the internal ear of a soldier who had died of epidemic meningitis, complicated with deafness, in which fibrinous adhesions existed between the bones of the internal ear and the walls of the vestibule. Dr. Klebs stated that in the recent state the mucous lining of the vestibule was detached. In the case of a young woman who was deaf from the commencement and died on the eighth day, "both tympana were natural, but in the left membrana tympani was found a dense white thickening as large as a pin's head. On the same side the lining membrane of the semicircular canals was distinctly thickened and loosed, and in the anterior canal there were semifluid purulent masses." Professor Knapp also states: "The nature of the ear disease is in all probability a purulent inflammation of the labyrinth." According to him, no disease of the middle ear could cause such complete deafness; and as evidence that the deafness is not due to central disease, Dr. Gruening obtained by electrization the normal reaction of the auditory nerve within the cranium. Moreover, if the lesion which destroys hearing be within the cranium, why is not the functions of the other cranial nerves also abolished? Moreover, Drs. Keller and Lucæ have in three post-mortem examinations found evidences of disease of the labyrinth.

An argument in support of the former of these theories is the fact that the lesion which produces the deafness is not ordinarily attended by any marked subjective symptoms referable to the ear, as otalgia, etc. Again, the

fact that the deafness is nearly always bilateral and simultaneous in the two ears, comports better with the doctrine of a central lesion, than with that which locates the lesion within the ear. But the true theory can only be positively established by dissections, and, as we have seen, several post-mortem examinations have revealed inflammatory disease of the labyrinth in those who have died having this form of deafness; while in no case, so far as I am aware, has the ear been found free from inflammatory lesions. Therefore the theory which ascribes the deafness to disease of the ear is much better established than the other, and must be accepted. Moreover, most of the aurists of this city, who have had excellent opportunities to examine these cases, believe in this theory.

(To be continued.)

THE TREATMENT OF ACUTE RHEUMATISM BY BLISTERS.¹

By FRANCIS P. KINNICUTT, M.D.,

PHYSICIAN TO ST. LUKE'S HOSPITAL, AND TO THE OUT-PATIENT DEPARTMENT OF THE NEW YORK HOSPITAL.

In the October number, 1881, of the *Dublin Journal of Medical Science*, appeared an interesting communication by Dr. Harkin on the pathology and treatment of acute rheumatism. The pathology of acute rheumatism is believed by the author of the above paper to consist in "a specific form of endocarditis of neuropathic origin, generally allied with myocarditis;" "in its unchecked progress speedily modifying the composition of the blood, the innervation and calorification of the body;" "in its ordinary course giving rise to lesions in the textures, the joints, the pericardium, pleura, the neurilemma, the meninges of the brain;" "in fine, in any organ accessible to nervous or arterial influence." Presumably guided by these views of the pathology of the disease, Dr. Harkin was led, after a trial of its efficiency in his own hands, to suggest the treatment of acute and subacute rheumatism, and also of gout, by means of large blisters *alone*, applied directly over the cardiac region. He regards their action as in no sense constitutional, but as wholly topical. If I correctly interpret his views, he believes that by aborting the endocarditis, the further manifestations of the disease, the implication of other textures, etc., may be prevented; and that very potent and safe means for such abortion are to be found in the local application of blisters. The blistering treatment of acute rheumatism has been recommended by various authorities, notably by Dr. Dechilly, of Vancoeurs, in France (1850), and by Dr. Herbert Davies, physician to the London Hospital (1864). Dr. Harkin's method differs from other methods in that, being based upon a different pathology, he applies the blisters to the cardiac region *alone*. In the paper referred to, Dr. Harkin gives the histories of thirteen consecutive cases of acute and subacute rheumatism, and in the *British Medical Journal* of September 23, 1882, of an additional case and also one of gout, treated by his method, and "practically without the administration of a single dose of medicine."

Although the histories of several of the cases lack completeness in the omission of the results of examinations of the heart, and in some other desirable details, the success reported in relieving the arthritic pains, in controlling the pyrexia, and in shortening the duration of the disease, was very satisfactory. It seemed to me, therefore, without accepting Dr. Harkin's views of the pathology of acute rheumatism, that his method of treatment was worthy of further careful trial and observation. During the early months of 1883, I, therefore, without any preconceived opinion as to the results, very closely watched the application of the blistering treatment in four consecutive cases of acute rheumatism, and in one

of gout, in my wards at St. Luke's Hospital. The method pursued was as follows: After a careful examination of the patient, a blister sufficiently large to cover the entire cardiac area was applied and allowed to remain until a very copious serous discharge was obtained; the blistered surface was then dressed and a second blister applied as soon as the condition of the skin permitted. The discomfort caused was less than I feared. No internal medication was employed in any of the cases, with the exception of small doses of opium, given at night when demanded by the sufferings of the patient, until a fair trial of the treatment had been made. The histories of the cases are given in detail for obvious reasons:

CASE I. *Gout*.—Male, aged forty, admitted March 13th. There is no family history of gout. The patient has been a free liver. He has had several attacks of inflammation of the great toes within the past two years. The present attack began one week ago; the pain was not severe until three days ago, when the great toe of either foot became swollen, red, and painful. Examination on admission: temperature, normal; examination of viscera, negative; urine, specific gravity, 1.018, acid, free from albumen and sugar; the great toe of both feet is swollen, red, and painful. Ordered rest in bed and a blister 4 × 5 inches to be applied over the præcordium.

March 14th.—The pain is less severe, there is less swelling and redness of the toes.

March 15th.—Patient is free from pain, although there is still redness and swelling of the affected joints.

March 16th.—There is slight return of pain in toe of left foot.

March 17th.—Absence of pain, swelling, and redness. The patient was permitted to remain in hospital until April 2d, although there was no return of the above symptoms.

CASE II. *Acute rheumatism*.—Male, aged twenty-nine. Admitted March 1st. There is no family history of gout or rheumatism. The patient has had two attacks of acute rheumatism previous to the present one. Four days ago the toes and ankles of both feet became swollen, red, and painful; later both knees and left hip became affected. Examination on admission: Temperature, 102 $\frac{3}{4}$ °. All the above-mentioned joints are acutely inflamed. The apex-beat of heart is within the mammary line; a distinct systolic basal murmur is heard, with greatest intensity over pulmonary area; the first sound at apex is slightly impure, but no murmur can be detected. Urine, specific gravity, 1.028; acid, free from albumen and sugar. Ordered a blister 4 × 6 inches to be applied over præcordium.

March 2d.—There is an abundant serous discharge from blistered surface. Temperature, 102 $\frac{1}{2}$ °. There is little, if any, change in the arthritic symptoms. The examination of the heart corresponds with that of yesterday.

March 3d.—Temperature, 102 $\frac{3}{4}$ °. A moderate dose of opium was given during the night to control pain. The pain is decidedly less in all the joints mentioned above, with the exception of the right knee, but the right hip has become involved. An examination of the heart shows no change.

March 4th.—Temperature, 101 $\frac{3}{4}$ °. Left knee, right ankle, and hip are very painful. Examination of the heart gives the same result as yesterday.

March 5th.—Temperature, 102 $\frac{3}{4}$ °. There is no diminution of the above arthritic symptoms, and the right shoulder is painful and swollen. A distinct systolic murmur is heard at apex.

March 6th.—Temperature, 102 $\frac{3}{4}$ °. There is no abatement of the joint symptoms. The apex murmur has become more distinct, and is transmitted to anterior axillary line. The basal murmur is harsher in character. Ordered a blister 3 × 3 inches, to be applied over præcordium.

¹ Read before the Practitioners' Society of New York, November 2, 1883.

¹ The temperatures were taken at the same hour each day, in all the cases.

March 7th.—Temperature, 102° . The patient's condition has not improved in any respect.

March 8th.—Temperature, $102\frac{1}{2}^{\circ}$. The right shoulder, wrist, and fingers, the left ankle and knee are swollen, red, and painful. Both murmurs are very distinct. Ordered ol. gaultheriæ, 3 ij., $\mathfrak{M}$ xl. daily, to be taken in divided doses every two hours.

March 9th.—Temperature, 101° . There is marked abatement in all the joint symptoms. There is no change in the heart murmurs.

March 10th.—Temperature, $100\frac{1}{2}^{\circ}$. There is no pain in joints, except on motion.

March 11th.—Temperature, $99\frac{3}{4}^{\circ}$. There is an entire absence of arthritic pain and tenderness.

March 12th.—Temperature normal. There is continued absence of arthritic symptoms. From this date the patient's convalescence progressed without any relapse. On two single occasions he complained of pain in right knee and shoulder for twenty-four hours; it was unattended with redness, swelling, or pyrexia. Both basal and apex murmurs persisted up to the date of the discharge from hospital, the latter being distinctly harsh in character and transmitted beyond the anterior axillary line.

CASE III. *Acute rheumatism*.—Male, aged twenty. Admitted March 18th. The patient's mother and two sisters have suffered from inflammatory rheumatism. The patient himself enjoyed good health previous to twelve weeks ago, when for the first time he was "laid up" with an attack of acute rheumatism. There have been two relapses, the second developing two days ago.

Examination on admission.—Temperature, $101\frac{1}{2}^{\circ}$. Both ankles, the toes of right foot, both knees, and right shoulder are affected. The apex beat of heart is within the mammillary line; a distinct systolic murmur is heard at apex. Urine, specific gravity, 1.024; alkaline, free from albumen and sugar. Ordered a blister 4×4 inches, to be applied over cardiac region.

March 19th.—There is an abundant serous discharge from blistered surface. Temperature, $102\frac{3}{4}^{\circ}$. There is no relief from pain, the appearance of the joints is unchanged, as is the character of the murmur.

March 20th.—Temperature, 101° . The arthritic pains are of greater intensity.

March 21st.—Temperature, $101\frac{1}{2}^{\circ}$. There is little if any change in the joint symptoms or the heart murmur.

March 22d.—Temperature, 101° . There is no relief from pain.

March 23d.—Temperature, $99\frac{1}{2}^{\circ}$. The patient is still suffering greatly.

March 24th.—Temperature, 100° . There is absolutely no improvement in any of the arthritic symptoms. The apex murmur is heard with the same distinctness as on admission. Ordered ol. gaultheriæ, 3 ij. daily, in divided doses every two hours.

March 25th.—Temperature normal. There is marked relief from pain, and improvement in the appearance of the joints.

March 26th.—Temperature normal. There is entire absence of pain. From this date the patient steadily and rapidly convalesced, without relapse. The apex murmur persisted and was distinct in character on the date of the patient's discharge.

CASE IV. *Acute rheumatism*.—Male, aged twenty-nine. Admitted March 23d. Both father and mother of patient have suffered from inflammatory rheumatism. Seven years ago the patient was confined to the house for ten weeks with an attack of acute rheumatism. Two weeks ago he began to suffer from present attack.

Examination on admission.—Temperature, $99\frac{1}{2}^{\circ}$. Both ankles, knees, the left elbow, and right wrist are very painful, swollen, and red. The apex beat of heart is within mammillary line; a faint systolic murmur, not transmitted, is heard at apex. Urine, specific gravity, 1.020; acid, free from albumen and sugar. Ordered a blister 6×6 inches, to be applied over precordium.

March 24th.—There is a profuse discharge of serum from blistered surface. Temperature, $100\frac{3}{4}^{\circ}$. There is no relief from pain. The fingers of both hands and the left wrist have become involved.

March 25th.—Temperature, $101\frac{3}{4}^{\circ}$. Morphine was given during the night to relieve pain. There is no change in the apex murmur.

March 26th.—Temperature, $100\frac{3}{4}^{\circ}$. There is no abatement in the arthritic symptoms.

March 27th.—Temperature, $101\frac{3}{4}^{\circ}$. There is slightly less pain in the affected joints.

March 28th.—Temperature, 102° . Both wrists, left knee, hip, and ankle are to-day exquisitely painful, swollen, and red. It is necessary to give full doses of opium to control the patient's sufferings. The apex murmur is more distinct.

March 29th.—Temperature, $101\frac{3}{4}^{\circ}$. Even with large doses of opium there is little relief from pain. The last mentioned joints are all acutely inflamed.

March 30th.—Temperature, $102\frac{1}{2}^{\circ}$. The patient's condition remains the same. The heart murmur is distinct, but is not transmitted beyond mitral area.

March 31st.—Temperature, $101\frac{1}{2}^{\circ}$. The arthritic symptoms persist with the same intensity. Ordered ol. gaultheriæ, 3 iv. daily, in divided doses, every two hours.

April 1st.—Temperature, 101° . The pain is still severe, but of less intensity than yesterday. No morphine has been given.

April 2d.—Temperature, $100\frac{1}{2}^{\circ}$. There is marked diminution in pain in all the affected joints. There is no change in the character of the heart murmur.

April 3d.—Temperature normal. The patient is almost wholly free from pain.

April 4th.—Temperature normal. There is an entire absence of pain. From this date convalescence steadily progressed without relapse. The apex murmur persisted up to the date of the patient's discharge.

CASE V. *Acute rheumatism*.—Male, aged twenty-one. Admitted April 3d. The father of the patient has been a sufferer from acute rheumatism. During the past ten years, the patient states that he has had eleven attacks of inflammatory rheumatism, in three of which all the large joints were affected. The present attack was developed five days ago.

Examination on admission.—Temperature, $102\frac{1}{4}^{\circ}$. Both ankles and left knee are painful, red, and swollen. The apex beat of heart is felt to the left of mammillary line; a reduplication of the first sound at apex is heard, which is believed to represent a systolic murmur. Urine, specific gravity, 1.034; alkaline, free from albumen and sugar. Ordered a blister 4×5 inches, to be applied over cardiac region.

April 4th.—There is a copious discharge of serum from blistered surface. Temperature, 102° . There is no diminution of pain.

April 5th.—Temperature, $102\frac{1}{2}^{\circ}$. The arthritic symptoms show no abatement in severity.

April 6th.—Temperature, 102° . There is no relief of pain. A satisfactory examination of the heart is impossible, on account of the pain produced by the blister.

April 7th.—Temperature, $102\frac{3}{4}^{\circ}$. The patient's condition is unchanged. The reduplication of the first sound at the apex has assumed the character of a loud systolic murmur.

April 8th.—Temperature, $102\frac{1}{2}^{\circ}$. There is no abatement of the joint symptoms.

April 9th.—Temperature, $102\frac{3}{4}^{\circ}$. The arthritic pains are of the same intensity. The first sound at the apex is replaced by a loud murmur. A presystolic apex murmur is believed to also exist. Ordered ol. gaultheriæ 3 ijss. daily, in divided doses every two hours.

April 10th.—Temperature, $100\frac{3}{4}^{\circ}$. There is no pain except in the right knee, on movement. A distinct diastolic and faint systolic murmur are heard at base, in addition to the apex murmurs.

April 11th.—Temperature normal. The patient is

free from pain. There was no further pyrexia during the succeeding twelve days, and there was an entire absence of arthritic symptoms. The oil of wintergreen was gradually reduced to 3 jss. daily.

On April 23d there was a slight rise of temperature, which disappeared in thirty-six hours, without the development of any arthritic symptoms.

On May 9th the temperature began to rise again, and there were physical signs of a developing pleurisy on the right side of the chest. Very moderate effusion followed.

May 18th.—The patient had a violent chill during the night. A careful examination shows dulness with bronchial respiration and bronchophony over a limited area in the posterior scapular region of the left chest, and over a larger area of the right, above the level of flatness. Temperature, $102\frac{3}{4}^{\circ}$. A pneumonic process is believed to have developed in the lower lobes of both lungs. The heart murmurs persist. The urine is free from albumen.

May 24th.—The bronchial breathing, voice, and dulness have been marked over the areas above mentioned since the last note; the temperature has remained at about 102° , and to-day there is a slight return of pain and redness in the metacarpo-phalangeal joint of left thumb. Temperature, $101\frac{1}{2}^{\circ}$.

May 25th.—Moist râles can be detected for the first time to-day over the affected areas on both sides of the chest. Temperature, $100\frac{1}{2}^{\circ}$.

May 27th.—Temperature normal. The dulness, bronchial breathing, and voice have diminished slightly in intensity; the râles are more numerous. From this date the physical signs of consolidation gradually diminished; there was no return of arthritic symptoms, convalescence progressed slowly but satisfactorily. On the date of discharge, double basal and apex murmurs were believed to exist.

The history of the above case has been continued from the date of the discontinuance of the blistering treatment as presenting many interesting points. It illustrates the efficiency of the salicyl compounds in controlling the arthritic symptoms of acute rheumatism, and, at the same time, their failure in many cases to combat further and different manifestations of the rheumatic virus.

A careful study of the above histories will indicate at least a fair trial of Dr. Harkin's method of treatment. The cases were not selected ones, but represent the first five patients suffering from gout and rheumatism, respectively, who were admitted to my wards after I had determined to apply the blistering treatment.

In Case I. the gouty symptoms extended over a period of nearly five days. It is a common clinical experience to observe such symptoms subside within this period without other treatment than simple rest. In the four cases of acute rheumatism, the blisters were used *alone*, with the exception of an occasional dose of opium, when rendered necessary by the sufferings of the patient, for seven, six, eight, and six days respectively; and only then were discontinued, and a salicyl compound substituted, from the fact that there not only was *no* abatement, but even an increase in the severity of the local (arthritic) symptoms, and a persistence of the constitutional. An analysis of the results of the examinations of the heart during the period of the blistering treatment will not be uninteresting.

In Case II. a basal systolic murmur, heard with greatest intensity over the pulmonary area, existed on admission. A very careful examination failed to reveal more than a slight impurity in the character of the first sound over the mitral area. The latter distinctly and progressively developed into a loud systolic apex murmur, transmitted as far as the anterior axillary line, during the period of the application of the blisters, and persisted up to the date of discharge from hospital.

In Case III. there was a distinct systolic apex murmur on admission, which persisted unchanged up to the date of discharge.

In Case IV. a faint systolic apex murmur, not trans-

mitted, existed on admission, and continued without change during the patient's stay in hospital.

In Case V. the heart was found to be enlarged on the first examination, and a reduplication of the first sound at the apex was heard. During the blistering treatment the reduplication was lost, a harsh systolic apex bruit was developed, together with a presystolic mitral murmur. Under the salicyl treatment there was a further development of the endocarditis, as evinced by the appearance of a double basal murmur.

In the thirteen cases reported by Dr. Harkin there is *no mention* of the heart in five; in two cases a mitral murmur existed before the application of the blisters, but no further reference to the condition of the heart is made. In two no cardiac affection existed before or during treatment. In two cases a mitral murmur, heard on the first examination, is reported as disappearing in the course of two and three weeks respectively. In the remaining two cases a mitral murmur was detected before treatment; in both a pericarditis developed during treatment, with a persistence of the mitral murmur in at least one of the cases up to the date of discharge.

A critical study of the above *résumé* fails, it seems to me (granting for the moment the correctness of Dr. Harkin's views in regarding acute rheumatism as a specific endocarditis), to demonstrate the efficacy of large blisters applied over the precordium, to control such an endocarditis. Moreover, my experience in the cases treated under my personal observation by his method has wholly failed to convince me of its power to affect on the one hand the endocardial affection, and on the other the severity of the arthritic symptoms and the degree and duration of the pyrexia. In conclusion I would add a few words in regard to the much discussed and criticized treatment of acute rheumatism by the salicyl compounds. Continued careful personal observation of their effects may be briefly summarized as follows:

First.—In controlling the arthritic symptoms (pain, etc.) and the pyrexia of acute rheumatism they may still be considered as constituting the most successful of all hitherto suggested methods of treatment. Their marked effect upon the pyrexia cannot be explained by their well-known antipyretic power *alone*.

Second.—While controlling the arthritic pains and pyrexia they seem incapable, in many cases, of wholly destroying the rheumatic virus, as is shown in the subsequent development of endocardial and pericardial affections and inflammations of other fibrous and serous textures.

Third.—Further proof is needed of a more frequent implication of the endocardium and pericardium under the administration of the various salicyl compounds than under any other hitherto advised treatment.

Fourth.—The most efficient, if not essential mode of their administration is in frequently repeated doses (every two hours), that the economy may be kept continuously under their influence; they should be continued in the initial doses during the first ten days of the disease, and given in very gradually diminished amount during the patient's entire convalescence.

Fifth.—Their possible anæmic effects may be rationally combatted by the use of iron salts before or with the beginning of convalescence.

Sixth.—A continued experience with the salicyl compound contained in the oil of wintergreen (methyl ether of salicylic acid), in the treatment of a large number of cases of acute rheumatism, confirms my favorable opinion,¹ expressed a year ago, of its efficiency and other desirable qualities. An efficient dosage is two and a half to three drachms daily. A simple and easy mode of administration is in sealed capsules, each containing ten minims of the oil.

I would express my indebtedness to Drs. Devlin, Beach, and King, members of the hospital House Staff, for their efficient assistance in the observation of the above recorded cases.

¹ MEDICAL RECORD, November 4, 1882.

THE RELATION OF PERINEPHRITIS AND PYONEPHROSIS TO MORBUS COXÆ.

By JOSEPH L. BAUER, M.D.,

LEHIGHTON, PA.

ABSCESSES in and surrounding the kidney have long since been recognized as distinct affections. Their detection is aided by definite rules of diagnosis; their prognosis, pathology, and treatment have been written with all the elegance of scientific language. And yet an important factor of the affection, interesting both to the physician and surgeon, has found no place in the books of some of our greatest surgical luminaries. Coxalgia occupies an important part in all surgical dissertations, but perinephritic abscess or pyonephrosis, in their surgical relations, is disposed of in a few brief sentences.

One would suppose that such orthopedists as Barwell, Bauer, Brodhurst, Hueter, Taylor, or Sayre would enlighten us upon those diseases which bear a near resemblance to coxalgia, and thus offer us some points of differential diagnosis. A careful examination of their literary labors fails to disclose such suppositions; in fact, periostitis of the femur seems to be the nearest relation to coxalgia, and occupies some space in their scientific analogies. Dr. V. P. Gibney, of New York, is the first to direct our attention to the great similarity between coxalgia and perinephritis. Up to that time the medical man had absorbed whatever interest attached to these diseases, and it would be justifiable to place the proper surgical value upon them. It shall be my object to strengthen and indorse the position of Dr. Gibney, and endeavor to secure professional recognition in this matter.

The following two cases are of absorbing interest:

CASE I. Perinephritic abscess; pointing at Scarpa's triangle; operation; death.—While living in St. Louis, my friend Dr. Grayson, of Venice, Ill., requested me to see a little lad, aged nine, who had consulted a prominent surgeon of St. Louis for supposed coxalgia. He stated that "it might run into hip disease," and advised the Hutchinson treatment. The boy grew worse rapidly, and I was called to render any assistance possible. An injury had been inflicted upon the right renal origin, the nature of which I cannot recall. I found him in bed, surrounded by the worst of hygiene, and a saturated malarial atmosphere. The face bore evidences of pyæmia; temperature, 104° F.; great thirst and loss of appetite; urine high-colored and very scanty. The body was greatly attenuated; abdomen enlarged and tympanitic; the right limb in extreme flexion and adduction, and an oval tumor discernible over Scarpa's triangle. He complained of constant pulsating pain over the tumor, as well as pain upon pressure upon the hip-joint; also reflex pains during the night. I tapped the abscess by introducing the exploring trocar in the outer aspect of the thigh, thus confirming my diagnosis of abscess. The next day I anæsthetized the patient, and succeeded in reducing the flexion and adduction entirely, and then made an incision in the outer aspect of the thigh, and succeeded in removing a large quantity of matter. A drain was introduced, and the cavity washed out with an antiseptic solution. *As soon as consciousness returned all pain in the joint ceased, and I could rotate the limb in any direction without any inconvenience whatsoever.* Examination per rectum disclosed no acetabular softening or perforation, nor was there any roughness of the articular surfaces. The limb remained in normal position, but the pyæmic condition continued, notwithstanding the constant flow of pus. During this time large quantities of matter passed with the urine. My patient grew rapidly worse, and succumbed to suppression of urine.

CASE II. Pyonephrosis; coxalgic symptoms; abduction of the right foot; treatment.—S. H.—, a married lady, aged twenty-three, consulted me for what her physician designated as "flying rheumatism?" She complained of constant pain in the back, in the knee and hip-joint as well as difficulty and pain on locomotion, knowing

that she suffered from hystero-epilepsy—having fractured her acromion from a fall down stairs during one of these attacks. I paid but little attention to the lumbar pain, nevertheless, I questioned her closely as to her secretions, and could learn nothing therefrom. Her limping and pain in the hip determined me in my diagnosis of incipient coxalgia, and I therefore suggested the most valuable and beneficial treatment of Hugh Owen Thomas, of Liverpool. The pain continued and increased in severity both day and night, and while the plaster dressing was still in situ, extreme abduction of the foot set in. Any effort to restore its position produced extreme pain, extending up the entire limb and into the abdominal cavity. I discarded the Thomas treatment and placed her in bed. In recumbency, the limb was completely abducted, and the pain increased in severity. Extension apparatus with weights and morphia gave some relief. During this time she frequently had attacks of urinary retention, which was relieved by catheter. One evening she experienced a sudden desire to pass water, which was accomplished without difficulty. The urine was admixed with large quantities of pus. *As soon as this occurred the coxalgic symptoms and pedal abduction disappeared.* As soon as the discharge ceased the same train of symptoms recurred. I then learned for the first time—false modesty having prevented the statement—that she had suffered from urinary difficulties previously. This opened my eyes, and upon examining the right renal region, I detected fluctuation but no enlargement. I did not see her for some time afterward. When I returned, I found a symmetrical enlargement of the abdomen, quite dull on percussion, and a diminution in the amount of urine. Fearing hydronephrosis from an occluded ureter, I determined upon consultation. After a careful examination by my friends, Drs. Reber, Horn, and Seiple, my diagnosis was agreed upon. While I should have liked to have used some surgical method to reduce the abscess, or determine the character of the abdominal enlargement, I deferred to more conservative suggestions, and waited for developments. The case is still repeating itself, the abdomen enlarging still more, and no further developments have taken place. Notwithstanding the great pain in the hip, and the abduction of the limb and foot, no intra-articular effusion existed, and I was compelled to rest upon the diagnosis of pyonephrosis.

Remarks.—Pyonephrosis may be due to embolism; direct injury to the renal organ; suppuration extending backward from urethra, bladder, ureter, or renal pelvis; irritation of, or the closure of some renal ducts, by calculi; tubercular disintegration, or the breaking-down of hydatid cysts, and pyæmic infection.

Roberts¹ says, that pyonephrosis is usually preceded by chronic pyelitis, terminating in the production of pus. The pyelitis usually owes its origin to calculous disease, and the impaction of a stone producing some obstruction. The same cause would naturally prevent the escape of pus forming in consequence of such inflammation. Blood-clot, tubercle, or any other morbid product causes the same effects. Perinephritis may be due to pyonephrosis—the renal abscess opening into the capsule—by extension of the inflammation from the kidney or renal pelvis. But more particularly to direct injury over the kidney may be ascribed the common cause of perinephritis, as in the case of the boy. I recollect the case of an adult in middle life suffering from lumbar abscess, due to injury and undoubtedly perinephritic, in which recovery was ensured by a deep incision and antiseptic ablutions.

Abscess of the kidney may pass into the renal pelvis and be discharged through the ureter, or may burst as in perinephritic abscess in any direction. Such cavities may open into the peritoneum, colon, or to the surface. It must be borne in mind that the psoas muscle arises in close proximity to the kidney, and that this fact, together with gravitation, would presuppose a selective affinity for

¹ Renal Abscess, by Fred. T. Roberts, M.D., F.R.C.P., Reynolds' System of Medicine, page 711. 1880.

the sheath of this muscle. In fact, authorities agree that this occurs in the majority of cases. Indeed, I can recall some cases of psoas abscesses, supposedly due to spinal caries, which were undoubtedly renal abscesses of some description.

This fact being disposed of, the question naturally arises: In what way can such abscess produce coxalgic symptoms? We must, of course, assume that the pus has penetrated the sheath of the muscle and has secured no outlet, *thus occasioning a constant pressure, in every direction, upon neighboring nerves and tissues.* We know, still further, that the nerves supplying the limb arise from the lumbar and sacral plexuses, and that the psoas muscle lies in close proximity to them; and it seems logical, therefore, if we conclude that the constant irritation surrounding the renal region, coupled with the pressure upon the surrounding nerve plexuses, must be the cause of the pain as well as the muscular contraction. Indeed, the retention of urine in S. H.— can be due to the same causes.

But it is in diagnosis and treatment that the greatest importance centres. If pus were always demonstrable in the urine the diagnosis would be comparatively easy. But this occurs *usually* in pyonephrosis, and only then when the secretory ducts are permeable. In case of closure of the ureter by calculus or other foreign substances the diagnosis is rendered more obscure. In perinephritis, also, no pus is present in the urine unless it has been due to the bursting of a renal abscess proper into its capsule. The urine must naturally be high-colored and contain excess of natural and some foreign elements, but, as we have to do with a pyogenic condition, no diagnostic weight can be attached thereto. In the case of S. H.— no tumor presented at Scarpa's triangle; but there was distinct pain over the lesser trochanter, seeming to indicate that the psoas muscle had been affected by the purulent infiltration. It is a clinical fact that irritation of certain muscles will occasion temporary inflammation of a joint, as in talipes valgus, and it would seem, therefore, as if the coxalgic symptoms were due to the contraction of the flexors, adductors, or abductors, as well as the disturbed innervation of the articulation. In the moment pressure is relieved by the copious discharge of such abscesses all pain and mechanical hindrances disappear. In the case of the boy the same result occurred. When the abscess was drained the various motions of the limb were absolutely painless.

Diagnostic differentiation is rendered very difficult in the initiatory stages; in that event, where there has been any history whatever of urinary trouble, conjoined with coxalgic symptoms, scientific accuracy would require a careful examination of the lumbar region. This would apply also where such history is absent. For it can be readily inferred that the mechanical treatment of coxalgia would be ill-applied in the condition mentioned, and that it would be extremely mortifying to the surgeon, who, desiring to divide muscular contractions, finds that anæsthesia dissipates them. In the stage of adduction and flexion, anæsthesia is probably the only means of relieving our uncertainty, unless the abscesses have already discharged. For, *in coxalgia, the muscular contractions and pain are neither relieved by anæsthesia or the creation of fistulous tracts.* And in coxalgia, also, we have the undisputed presence of either articular effusion or a defined roughness of the articular cartilages.

These abscesses either discharge themselves and get well, the pus becomes inspissated, or we must resort to surgical methods. If fluctuation over the kidney is evident, aspiration is the proper solution. Should this not suffice, deep incisions would be justifiable under antiseptic precautions, and, if found necessary, the kidney could be removed. Otherwise rest, and the usual anti-pyæmic remedies, with glorious expectancy, must be resorted to. Should the distention of the abdomen persist (S. H.—), together with further purulent infection, I should most certainly consider it proper to advise the most radical surgical methods.

Progress of Medical Science.

MODIFICATION IN THE SENSIBILITY OF THE SKIN OF THE ABDOMEN DURING PREGNANCY.—Dr. R. Teuffel (*Zeitschrift für Biologie*, vol. xviii., and *Bulletin de Thérapeutique*, August 15, 1883), has repeated the observations of Czernak relating to the marked diminution in the sensibility of the cuticle of the abdomen during pregnancy. He finds that there is a constant relation between the diminution in the sensibility of the skin and the distention of the latter. Other authors have failed, according to Dr. Teuffel, to agree regarding this interesting symptom, because of the fact that, during pregnancy, the elasticity of the skin varies notably in different individuals and that consequently the relative degree of distention is likewise variable. In the neighborhood of the *striæ*, where the distention reaches its maximum, the diminution in the cutaneous sensibility is much more pronounced than at any other point.—*Journal de Médecine de Paris*, September 29, 1883.

TRICHLORACETIC ACID AS A REAGENT FOR THE DETECTION OF ALBUMEN IN URINE.—Raade proposes the following process for the ready detection and quantitative estimation of albumen in urine. Add a small quantity of the acid to the suspected urine, allowing it to glide along the inner surface of the test-tube holding the urine. The latter should not be agitated. A turbid zone of coagulated albumen is formed, if the latter be present, and does not disappear when heated, as do the urates. The urates are not, however, precipitated when the urine is diluted with one-third its volume of water. A quantity of albumen equal to .0295 gramme may be recognized by this test in 250 c.c. of urine. The relative sensitiveness of the tests for albumen by metaphosphoric acid, nitric acid, and trichloracetic acid may be represented numerically by the figures 1, 3.7, 6.2.—*Bulletin Général de Thérapeutique*, September 30, 1883.

APHASIA AND AGRAPHIA IN TYPHOID FEVER.—Dr. Baas, of Mayence, mentions in the *Deutsche Med. Wochenschrift* a case of aphasia and agraphia, with paralysis of the right facial nerve and of the right arm, in a boy eight and a half years of age in the course of a severe attack of typhoid fever. The paralysis appeared on the twenty-first day, when the sensorium was much affected; the other symptoms were first noticed on the return of consciousness. The patient could not pronounce either words or numbers, although he held up his fingers correctly to express a number suggested to him; and the scrawls which he made on attempting to write were the source of great amusement to him, as he saw them so different from what he intended to make. There were no signs of improvement in the aphasia until eight weeks from the commencement of the illness, but then the boy began to learn step by step anew to speak and to write, and by the end of the month he could do both well. The lesion was probably a capillary apoplexy in the left third frontal convolution and its neighborhood.

HOW TO GIVE QUININE.—Dr. Young, from an extended experience with quinine, in the febrile affections occurring in Rome, Italy, concludes as follows: 1. Never to give quinine in antipyretic doses in cases where the bowels are confined and the secretion of urine is scanty. 2. In cases where it is being administered and an increase of dose is desirable, this may be safely done if the skin, bowels, and kidneys maintain their normal functional activity. 3. In many cases of remittent and intermittent fevers, the combination of the drug with chloride of ammonium or a salt of potash or soda is likely to be more easily tolerated as well as more useful than if it be administered in a pure form. 4. During the administration of quinine, should a headache come on or increase in intensity, the case requires the most careful attention.—*The London Practitioner*, October, 1883.

SPASM OF THE TONGUE.—E. Ganghoffner (*Centralbl. für die Med. Wiss.*) describes the following case: A youth, aged nineteen, had from infancy suffered under a spasmodic affection of the muscles of the tongue, which, when he began to speak, protruded from his mouth. Simultaneously with this movement he experienced jerking of the right lower extremity. In repeating by heart a poem, in singing, or in rapid speaking the spasm of the tongue would pass off. The patient was anæmic, but otherwise in good health. When not speaking, he seemed to have nothing about him abnormal. His mother had suffered from deafness from her childhood; a brother also had presented a similar defect of speech; a sister was epileptic. Treatment by bromide of potassium had no influence over the spasms. Doubtless this was a case of chorea, the spasm of the tongue being a local manifestation of this neurosis.

INTERSTITIAL NEPHRITIS OF BACTERIAL ORIGIN OCCURRING IN CHILDREN.—Dr. Ludwig Letzerich writes in the *Allgemeine Medicinische Central-Zeitung* of September 29, 1883, concerning a peculiar inflammation of the kidneys occurring in children, independently of any of the acute exanthemata, which he observed and studied during the past spring and summer. There were twenty-four cases, all presenting exactly similar symptoms, and in all of which the same bacterial forms were found in the urine. Three children died of acute uræmia, the others recovered. The micro-organisms voided with the urine were cultivated through four generations, and then used in experiments upon rabbits. In every case the kidneys presented the same macroscopical and microscopical appearances as were found in the three children dying of this nephritis. The micro-organisms were in the form of rods resembling the bacilli of typhus, but somewhat longer and broader than these. When cultivated, the organisms formed no closed micrococci colonies from which the rods were developed, as is the case in the typhus organisms, but appeared as a mycoderma, as true bacilli. In the interstitial tissue of the kidneys they were seen in large collections from which long threads were traced to the cortex and medullary substance. The kidneys were very hyperæmic, and in places broad, dark red, almost black lines were visible. There were collections of wandering cells in the interstitial tissue. Dr. Letzerich thinks that the organisms were taken in with the drinking-water, though further investigation is necessary for the elucidation of this point.

DYSMENORRHOEA.—There are few subjects more worthy of sound study than dysmenorrhœa. It has received for the last fifty years more attention at the hands of gynecologists than ever before. But still it cannot be said that authorities are agreed on its essential causes. For a long time it came to be regarded as eminently a case for treatment by specialists. The mechanical theory of its causation largely ruled practice, in some few cases with brilliant relief, and perhaps cure, in others without success, and often with the effect of adding to the mischiefs which it was intended to remove. The very nature of the complaint, and the fact that in its serious forms it affects chiefly unmarried women, render the complete investigation of it a matter of much difficulty. The existence of more or less dysmenorrhœa in the majority of women is a fact. Even those who are unwilling to recognize in this fact any argument against the capacity of women for competing in the labor market with men do not deny that in a large proportion—nearly fifty per cent.—this dysmenorrhœa is considerable in amount.

In a paper by Dr. John Williams on the natural history of dysmenorrhœa, read before the Obstetrical Society of London, he divides his cases into two sets—first, cases of primary dysmenorrhœa; secondly, cases of acquired. The acquired cases are so few (22) compared with the others (873) that we need not here allude to them. His conclusions are as follows: "Dysmenorrhœa should be studied first under the least complex conditions—in

single women. 2. Dysmenorrhœa in single women is rarely acquired; it is almost invariably primary—viz., it appears with the menstrual function. 3. Dysmenorrhœa in a few, but rare, cases ceases spontaneously a few years after puberty. 4. Marriage, if sterile, aggravates the disorder in many cases; it is only very seldom that it relieves the pain. 5. Child-bearing cures a large number of cases, and it is not impossible that were all puerperal complications excluded it would cure every case. 6. The proportion of sterile to fertile women subjects of primary dysmenorrhœa is one to twelve. 7. Menstruation begins in women who become sufferers from primary dysmenorrhœa at about the estimated average age for the appearance of the function in London. 8. Menstruation is regular in about two-thirds of the cases, and irregular in about one-third. 9. The menstrual fluid is profuse in about two-fifths of the cases, scanty in about one-half. It contains clots or shreds in about three-fourths. 10. The changes which take place in the fluid in the course of dysmenorrhœa are various, and cannot at present be classified. 11. The uterus is imperfectly developed. It may be too short, or too small in volume, or it may be defective in both respects. The cervix may be conical, and the os small and round, but stricture of the canal in any part of its course is infinitely rare. 12. The changes in the uterus due to dysmenorrhœa are slight hypertrophy, erosion and eversion of the mucous membrane of the cervix, and catarrh. The cavity increases but little in length, for after years of suffering it measures rarely more than two and a half inches in length. In the early stages the tissues of the uterus are in some cases soft; in the more advanced, hard. 13. The hypertrophy of the uterus is probably the result of periodically increased muscular action. 14. Ovaritis and perimetritis are possible consequences of dysmenorrhœa. 15. The menstrual pain is the result of spasm of the uterus, excited by the separation and expulsion of shreds of decidua and clots, in an organ whose sensitiveness in the performance of its function is enhanced by inappreciable conditions of tissue dependent on imperfect development, often associated with others, such as anæmia."—*The Lancet*, September 15, 1883.

CONCUSSION OF THE BRAIN IN A YOUNG CHILD.—At the recent meeting of the French Association for the Advancement of Science, held in Rouen, Dr. Cartaz related a case of transitory hemiplegia, due to cerebral concussion in a child two and one-half years of age (*Gazette des Hôpitaux*, September 29, 1883). The patient fell, striking the back of his head on the floor. When he was raised up it was observed that he was unable to support himself on the right leg. M. Cartaz found right hemiplegia without anæsthesia, and incomplete facial hemiplegia with aphasia. The child was quiet, there were no convulsions and no coma. There was no lesion of the cranium discoverable, nor was there any febrile reaction. Three days after the injury the child articulated a word that he was accustomed to employ frequently in ordinary conversation. In another three days he had regained the power of speech, and was able to walk, dragging his leg slightly. At the end of another week he had completely recovered. In consideration of the rapidity of the development of the symptoms, the localization of the paralysis (right hemiplegia of both face and trunk), and the absence of any febrile reaction, the author was led to regard the condition as one of concussion of the brain.

ERYTHRASMA.—Dr. Besnier thus describes this little-known though, as he states, rather frequent affection: It occurs in patches having somewhat the appearance of intertrigo, but presenting a slight pigmentation. These patches, of a more or less rounded form, occupy sometimes a pretty considerable extent of surface. They are seen in the axilla, between the thighs, on the scrotum, in all parts where intertrigo is met with. In the parts where the integument is free from folds the patches present a

pale red color, whence the name of erythrasma. There is but little itching and no constitutional reaction. It is a parasitic disease, the parasite of which, extremely minute and only to be seen by means of the immersion lens, bears the name of *microsporon minutissimum*. The affection is to be distinguished from simple discolorations of the skin by the pruritus and a slight branny desquamation. It is differentiated from herpes tonsurans by its uniformity of color from the centre to the periphery of the patch as well as by its degree of pigmentation. From pityriasis versicolor it is distinguished by this same pigmentation and by the impossibility of raising any scales by the scraping of the finger-nail. The affection is devoid of gravity.—*Revue Médicale*, October 6, 1883.

INFLUENCE OF DIPHTHERIA UPON PREGNANCY.—In a communication addressed to the Academy of Medicine of Paris (*Archives Générales de Médecine*, October, 1883), Dr. Ollivier concludes that diphtheria may acquire an additional gravity when occurring in pregnant women, because of the liability it has to cause abortion. This accident is due, in the larger number of cases, not to asphyxia nor to an elevation of the temperature of the blood but to some alteration in this fluid, an alteration which, if it is undefined, is nevertheless incontestable. The possibility of abortion with its dangers calls for increased precautionary measures and more strict isolation in the case of pregnant women in the same house or in the same hospital ward with patients suffering from diphtheria.

A NEW APPLICATION OF TENOTOMY.—The limited power of extension possessed by the ring-finger is sometimes of great inconvenience, especially to pianists. In the case of men in whom this condition was very marked Dr. Forbes recently divided the cross fibres connecting the tendon of the extensor communis for the ring-finger with those passing to the middle and little fingers. The operation was almost painless and the wound healed quickly, leaving an almost imperceptible scar. Before the operation the finger could be raised scarcely one-fourth of an inch, but after the tenotomy it could be extended one and one-fourth inch, and lost nothing of its strength in consequence.—*Wiener Med. Wochenschrift*, September 22, 1883.

BILATERAL HALLUCINATIONS DIFFERING IN CHARACTER ACCORDING TO THE SIDE AFFECTED.—Hallucinations affect usually the senses on both sides symmetrically, that is, the subjective images or noises seem to be perceived by both eyes or both ears in equal degree. Sometimes, as noted by Cahneil, Moreau, and others, they are unilateral and the sounds are heard in one ear only, or images are perceived by one eye alone. In other rare cases the hallucinations are bilateral but find different expression on the two sides. The right ear, for example, hears only flattering and pleasant remarks while insults are poured into the left ear. At the recent Congress of the French Association for the advancement of science, Dr. Magnan related several instances of this peculiar condition. In one case the imaginary sounds were at first confined to the right ear, and were of an insulting nature. After a time the patient began to hear prophecies of success and riches, encouraging and commendatory voices in the left ear. Sometimes he heard bells ringing; when they were heard in the left ear they were of good omen, but when in the right they foretold, he said, the approach of evil. The good and the evil genii thus ruled him in a sort of Manichæism. In three other patients delusions of an ambitious nature were manifested through the organs of sense on the right side, while on the left the hallucinations were of a saddening character. M. Magnan summed up his conclusions derived from a study of these cases as follows: 1, bilateral hallucinations of a double character are independent of any local disturbances in the organs of sense; 2, they differ in no way from the more common forms of delusions either by their manner of apparition or by their

general characters; they are an additional proof of the functional independence of the cerebral hemispheres; their organic seat is in the sensorial centres of the cortex; 4, experiments conducted upon patients in various states of hysterical hypnotism corroborate in all points the results of clinical observation.—*Revue Médicale*, September 22, 1883.

SUBPERIOSTEAL RESECTION OF THE HUMERUS WITH OSSEOUS REPRODUCTION IN AN ADULT.—Dr. Nicaise reports the following rare instance of the growth of new bone after resection in an adult. In 1871 he performed a subperiosteal resection in a man, thirty-three years of age, whose humerus had been shattered by a bullet, the radial nerve being also severed. Suppuration ensued, and the operation was performed eighteen days after the receipt of the injury. Numerous loose sequestra were removed and also a necrosed portion of the upper fragment, two inches in length, to which a portion of the deltoid was attached. After the operation there was a separation between the two fragments of the humerus of between five and six inches, the interval being occupied only by the ragged periosteum. No attempt to approximate the two ends of the bone was made, but the arm was placed in a splint so as to maintain the limb at its full length. Repair proceeded rapidly, and so complete was the reproduction of osseous tissue that after seven months it was impossible to detect the line of union between the old and new bone. The arm was shortened less than half an inch. The radial paralysis persisted and led to atrophy of the muscles supplied by that nerve, yet the patient was able to resume his work as a stone-cutter. He remained in excellent health for eight years, and then had an abscess in the arm, which, however, healed readily under appropriate treatment. Dr. Nicaise, thinking that the constant jarring of the new bone from the use of the mallet might have caused an osteitis, advised rest or the choice of some other occupation, but his advice was unheeded. The patient continued at his work for three years longer, when, after severe pain of several weeks' duration, abscesses and fistulæ formed in the arm. The suppuration was profuse, and the patient became emaciated and feverish. A spontaneous fracture having taken place, the arm was disarticulated. In the upper portion of the reproduced bone there was found fungoid osteitis with a formation of sequestra which had led to its separation from the old bone. The surface of the new bone was rough and channelled by numerous blood-vessels; the periosteum was thickened and closely adherent. The upper end of the old humerus showed signs of a chronic osteomyelitis.—*Centralblatt für Chirurgie*, September 29, 1883.

ACUTE ASCENDING PARALYSIS.—A case of acute ascending paralysis (Landry's paralysis), eventuating in recovery, is reported by Dr. Lamberto Antonini. The patient was a small, slightly built, delicate woman, fifty-five years of age, originally of good health, but who had suffered from uterine disorders since the birth of the second of her seven children. She was somewhat nervous and presented some slight hysterical manifestations, occasional hot flashes, globus, and headaches. One morning she felt a little weakness of the limbs, which gradually increased to a complete loss of power. Examination showed motor paralysis of the lower extremities, so that only very slight movements of the feet were possible, relaxed muscles, but no atrophy. Sensibility, tendon and skin reflexes were normal; there were no painful pressure points over the spine, no feeling of constriction in the abdomen; sight was unimpaired; the pupillary reactions were normal; there was no headache; the intellect was unaffected; deglutition and the functions of the bladder and rectum were normal; the temperature was from 100° to 102° F. On the evening of the second day the patient complained of a tired feeling and formication in the hands, and the following morning there was complete paralysis of the upper extremities. There was also

difficulty of respiration and the feeling as of a heavy weight upon the chest. All the symptoms increased in severity up to the seventh day, and then continued without change for five days longer. The dyspnoea reached so threatening a point that the doctor and patient momentarily expected the end. The electrical examination, made while the disease was at its height, showed perfectly normal muscular and nervous reactions to both the galvanic and faradic currents; no reaction of degeneration. On the twelfth day the patient was able to move the arms and fingers, and the following day the dyspnoea and paralysis of the lower extremities began to mend, so that on the sixteenth day all the paralytic symptoms had disappeared. A double hypostatic pneumonia arose about the tenth day and confined the patient to her bed for six weeks. The temperature during the course of the primary disease varied from normal up to 102° . There was no enlargement of either liver or spleen, and there were no bed-sores. The treatment consisted, during the first few days, in purgatives and in wet cups along the spine; later, blisters and the internal administration of excito-motor remedies with wine and quinine. Repeated observations have shown the permanence of the cure.—*Centralblatt für Klinische Medizin*, September 29, 1883.

THE CONTAGION OF TUBERCULOSIS.—The following are the conclusions arrived at by M. Darnberg in a communication addressed to the Academy of Medicine of Paris (*Bulletin de l'Académie*, October 7, 1883): 1. Tuberculosis is a disease of parasitic nature, transmissible by inoculation, alimentation, or inhalation. 2. It is always caused by the absorption of a germ from without. 3. When occurring by inhalation the quantity of the contagion is of little moment. It can operate only in a suitable soil. In a word, contagion is an influence to which all are exposed, but which is operative only in those individuals in whom hereditary or acquired vices of nutrition have prepared a field suited to the growth and reproduction of the germ. 4. Local and general tuberculosis differ only in degree. 5. Scrofula appears to be a diathesis, while tuberculosis is an infection engrafted upon diatheses. 6. The infectious germs of tuberculosis are not usually inherited, but rather the vices of nutrition which have provoked the disease in the ancestors. 7. Therapy, while permitted to seek for specifics, ought, in the way of prophylaxis, to aim at the destruction, through general hygiene, of the causes which prepare a fit soil for the reception of the tuberculous contagion. After the disease is established it should seek to combat the phenomena arising in the economy from the presence and proliferation of the infectious agent.

DOUCHES OF COMPRESSED AIR.—Dr. Maurice Dupont publishes in the *Bulletin Général de Thérapeutique*, September 30, 1883, an original article on the above subject. He employs air under a pressure of three atmospheres, which is allowed to escape through a tube made of the material used in the manufacture of gum-elastic catheters, provided with a nozzle, the orifice of which measures from 8 to 10 millimetres. The jet of compressed air is directed upon the bare skin of the patient, who either stands or assumes a recumbent position. The first result of the flagellation is to compress the superficial tissues of the flagellated area and to repel the blood from the peripheral capillaries into those of the deeper parts. Refrigeration of the surface thus treated at once ensues, only to be succeeded by a rapid reaction, which is indicated by marked rubefaction of the skin. The patient does not need friction after the douche, as is the case when the cold water douche has been employed, and since he is not wet, there is no danger of subsequent depressing refrigeration resulting from evaporation. If excessive refrigeration be desired a few drops of liquid may be mingled with the jet of air, a genuine pulverization of the fluid thus obtained and local hemianæsthesia

produced by the rapid evaporation on the cutaneous surface. After the douche the patient experiences an agreeable sense of warmth in the skin, due to the reactionary congestion which rapidly appears, owing to the energetic percussion exerted on the cuticle by the strong current of air. Dr. Dupont regards the douche of compressed air as indicated (1) in pulmonary tuberculosis, chlorosis, anæmia, and obesity, to modify nutrition; (2) in œdema, hydrarthrosis, and ankylosis, to stimulate the circulation and to favor the reabsorption of effusions; (3) in contractures and hyperæsthesias the air-douche has anæsthetic properties, easily augmented by the addition of carbonic dioxide; (4) the air-douche may be a useful adjuvant to electricity in paralysis.

VISIBLE CAPILLARY PULSATIONS.—M. A. Ruault recently read a paper before the Clinical Society, which relates to the visible capillary pulsations. The symptomatic value of this phenomenon was first indicated by Quincke. According to this author the capillary pulse, indicated by alternate redness and pallor of the tissues concerned, isochronous with the cardiac systole and diastole, is specially observed under the finger-nails in healthy subjects, as well as in slight chlorosis and particularly in aortic insufficiency. It is occasionally accompanied by a similar pulse visible at the fundus oculi, by the ophthalmoscope. M. Ruault's communication relates, however, to a variety of visible capillary pulse which may be observed on a so-called vaso-motor spot,* produced by rubbing the forehead with the finger-nail. The capillary pulse is plainly seen in these congested areas if the observer's eye be maintained at a distance of thirty or forty centimetres from them, and the cardiac pulsations are easily counted. M. Ruault has never observed the capillary pulse in healthy persons, but in chlorotic patients and in those suffering from lead poisoning, whose arteries presented the fibroid degeneration known as arterio-sclerosis. The pulsations in question were most constantly observed, however, in patients with aortic insufficiency, especially in those whose cardiac action was regular and strong. It therefore seems that the capillary pulse can only occur in those pathological conditions attended by co-existing augmented cardiac impulse and general arterial contraction, as is frequently the case in arterio-sclerosis.—*Journal de Médecine et de Chirurgie Pratiques*, October, 1883.

BLOODY TEARS.—M. Damalix has published an article relating to the rare phenomenon of sanguineous lachrymation. He cites two well-authenticated cases of this curious affection, reported respectively by M. Hasner and by M. Brun. In these cases the eyes filled quickly with the bloody tears, the sanguineous character of which was demonstrated by microscopical examination. This affection is to be carefully distinguished from hemorrhages dependent upon orbital or conjunctival disease, such as polypoid conjunctival vegetations developed in the *cul-de-sac* of the conjunctiva. Genuine bloody tears are quite independent of any ocular or conjunctival disease and their appearance is irregular. No apparent cause leads to their effusion. In some cases the escape of the tears is unattended by pain. In others the patient experiences pain in the forehead, the eyebrow, and at the root of the nose, or a sensation of pruritus, formication, or heat in the eyelids. These morbid sensations persist only a few instants and disappear with the appearance of the tears. The escape of the tears continues only a few minutes and the quantity of sanguineous lachrymal secretion varies from a few drops to a wine-glassful. This phenomenon is usually intermittent, sometimes regular, but almost always transitory and attended by hemorrhages from various cutaneous or mucous surfaces. Sanguineous lachrymation appears, by preference, in anæmic individuals, in those inclined to hæmatophilia and in hysterical women.—*Journal de Médecine et de Chirurgie Pratiques*, October, 1883.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, December 8, 1883.

CONCERNING THE DANGER FROM CONTAGIOUS DISEASES THROUGH THE CIRCULATION OF BOOKS.

SOME time ago we referred to what we considered highly sensational and ill-considered remarks made in *The Lancet* and *British Medical Journal*, regarding the danger from contagious diseases through the circulation of books. We stated at the time that the subject had been very thoroughly investigated in this country, and that our English contemporaries were evidently quite ignorant of the results thus obtained. However, the alarmist cry, issued from London, has been caught up and widely echoed by various medical and lay journals. Therefore we venture to return to the subject now.

In 1878 the directors of the Chicago Public Library appointed a committee to examine into this question of the communicability of contagious diseases through the agency of books. After a careful investigation, Mr. W. F. Poole made a report in 1879. He had corresponded with the librarians of all the principal libraries in this country, and with nineteen medical and sanitary experts. Not one of the latter gentlemen had ever known of a case of contagious disease communicated by books from public or private circulating libraries. This fact is especially significant when we remember the enormous number of books annually circulated. The total number of large public libraries in the United States in 1881¹ was 3,988, containing 12,889,598 volumes, and the number of books circulated annually is, at a low estimate, 9,912,760 (883 libraries reporting). In some large libraries more than a dozen assistants are employed, who are constantly handling and moving among the books. Yet, according to the reports of the librarians, no case of contagious disease among these, communicated by the books, had been known. A recent statement from Mr. Peoples, librarian of the New York Mercantile Library, is to the effect that this immunity has continued for the four years since the inquiry of Mr. Poole was first made.

Dr. Green, of Boston, who examined this matter carefully in 1872, when an epidemic of small-pox was raging in that city, stated that among 4,700 cases whose history was obtained, in not one instance was the origin referable to books.

So far as the evidence shows, therefore, we have no

reason to believe that there is practically any danger from this source.

Discussing the question from a purely theoretical point of view, it cannot be denied that a paper-covered book can carry the contagion of scarlet-fever and small-pox. A few cases originating in this way through private volumes are alleged to have occurred. We cannot say, however, that even the evidence for this is positively established.

The danger so sensationally heralded is, therefore, so slight that it can be, in ordinary times, ignored. When contagious diseases are extensively prevailing, or an epidemic occurs, it will, of course, be proper to take precautions. These consist in the notification to librarians by the health officers of infected dwellings. It is also recommended to dust the shelves with an antiseptic powder.

TO SECURE A NEW MEDICAL LAW.

THE profession of the State has received a new evidence of the enterprise and earnestness of the Erie County Medical Society in its efforts to secure reform in our method of creating medical men and regulating medical practice. A circular notice has been sent out by the Committee on Legislation, the notice including a copy of the proposed bill to be submitted to the next Legislature, a memorial presenting succinctly the arguments for the bill, and a personal letter asking the attention of individual physicians to the matter.

The general tenor of the bill is already well known. It authorizes the appointment by the Governor of nine medical men, who shall constitute the "Medical Faculty of the University of New York." Six of these gentlemen are to be members of the regular school, two of the homœopathic, and one of the eclectic. After June 1, 1884, all persons desiring to practise medicine in this State must present themselves before this faculty, which is to meet semi-annually, show a diploma from a legally incorporated medical college, and pass a satisfactory examination. They must then register in the County Clerk's office.

The bill thus takes away from the colleges the licensing power and transfers it to an independent board, none of the members of which are connected with any medical college.

There is no question that the sentiment of the profession of the State is unanimously in favor of the objects of this bill. The only thing to be feared is that the proposed board may get into the hands of politicians, and this possibility will have to be carefully looked after. We do not despair of being able to avoid such catastrophe. There is no more pressing necessity before the profession of the State than that of putting some check upon the present practice of pouring annually masses of half-educated stupidity upon us. "If a young man is a dunce, why he is good enough to be a doctor." This is getting to be a common expression among the *commune vulgus*.

Fortunately we have not only moral but legal grounds upon which to demand help from the State. Physicians have to furnish official notices of births, deaths, and the existence of infectious diseases, and are called upon for expert testimony in other capacity. The State must have some proof that these men are competent. Let

¹ Report of Commissioner of Education.

the doctors of the State not imitate the apathy of some of their Massachusetts brethren, who fold their hands and say weakly, "Medical legislation has always failed, let us abandon it." Medical legislation has not always failed, and it need not now if physicians will continue to work in earnest.

THE COMMUNICABILITY OF PHTHISIS.

WE are told on the authority of the *British Medical Journal* that the most striking and probably most valuable part of the work done by the Collective Investigation Committee has been that relating to the communicability of phthisis. One thousand and seventy-eight replies were received to the circulars sent out. Of these 673 were simple negatives, while 261 replies affirmed the proposition that phthisis may be communicated from the sick to the healthy, and afforded evidence in support of that opinion.

Out of these 261 affirmative replies 192 were accompanied with reports of cases illustrating the communicability from husband to wife or the reverse, and in 130 instances it is stated that no family history of the disease existed in the parties to whom the disease was transmitted.

On the other hand 105 persons testified in their belief that the disease was not communicable.

The facts thus elicited show that a small proportion, probably less than five per cent., of general practitioners have met with evidence which leads them to believe that consumption is contagious. Considering the numerous sources of error in observations of this kind, we can not consider that certainty has yet been reached. If consumption is contagious, it is very feebly so, and the simplest precautions ought to be sufficient to prevent it.

THE TREATMENT OF FRACTURED PATELLA.

THE question of the best treatment for fractured patella has recently been brought into prominence. The medical and clinical societies of London at their meetings in November made the matter the subject of prolonged and animated debates, during which some interesting statistics were brought forward by Mr. G. R. Turner and Mr. Bryant. Dr. William Macewen also contributed a paper on the same subject in the *Lancet* of November 17th. The chief point at issue was the adoption of the practice of cutting into the knee-joint, drilling the two fragments, and uniting them by a stout silver wire, the whole being done under the strictest antiseptic precautions. The question further was, whether, admitting that the operation is justifiable in old and intractable cases where the leg is almost useless, it is also justifiable in recent cases. The early operation received the qualified endorsement of Mr. Lister, and the unqualified and earnest support of Dr. Macewen.

The statistics presented by Mr. Turner, however, showed that this operation is not without danger to life and limb, while the statistics of Mr. Bryant and the general experience of other surgeons showed that the treatment of fractured patella by simpler methods was attended with just as good results as was the more radical operation.

The debates on the whole show, as stated by the

Lancet, that the operation was not suitable as a primary measure, nor for general employment. That when performed the operation should be done with every possible antiseptic measure, and that when, as in intractable cases, it is positively indicated, the earlier the operation is performed the better.

THE PTOMAINES OR CADAVERIC ALKALOIDS AND THEIR SIGNIFICANCE.

IT is only of late years that it has been known that a short time after death there may develop in the body certain poisonous and non-poisonous alkaloids whose chemical and physiological action resembles that of the poisonous vegetable alkaloids. The knowledge of this fact is a most important one from a forensic point of view, and no medical man should allow himself to be ignorant of it. A very good summary of what is so far known regarding these substances has been given recently by Mr. R. N. Wolfenden.

Ptomaines begin to develop in the body within two or three days after death. It is said by some that they cannot be isolated in a crystalline form; hence their exact composition is unknown. But they undoubtedly resemble the vegetal alkaloids, and their presence is readily detected by proper tests. The ordinary test first put forward by Brouardel and Boulmy consists in adding a little sulphuric acid to the solution in order to produce a sulphate. A drop or two of a solution of this sulphate added to a solution of ferrocyanide of potassium turns the latter into a ferrocyanide (Attfeld), and the mixture then gives a dark blue precipitate with a ferric salt. Unfortunately other alkaloids give this same reaction. A French chemist has affirmed that though we can determine confidently the presence of a ptomaine and of a vegetal alkaloid, yet when the two exist in the tissues it is not possible by present methods to separate the reactions.

Subjected to physiological tests, some of these ptomaines act like strychnine, others like nicotin, muscarin, atropin, etc. The physiological tests are, however, the most important, and are the ones to be finally depended upon.

Some ptomaines seem to act like the venom of snakes, and it is probable that these two classes of poisons are allied in chemical character.

Gautier and Selmi have found that ptomaines exist in the living body in pathological and even in normal fluids. The former observer states that he has found a poisonous (to lower animals) alkaloid in normal urine and in fresh saliva. It remains to be seen, however, that he has not confounded the effect of these alkaloids with that of specific organisms. Selmi has found two poisonous alkaloids resembling conine and nicotin in the urine of patients suffering from progressive paresis. He has also found two alkaloids in the urine in cases of interstitial pneumonia, and two others in cases of typhoid fever. Alkaloids have also been found in the urine of miliary fever and of tetanus. It is suggested that some of the uræmic phenomena may be due to these substances.

Ptomaines vary much in number and character, according to the length of time during which putrefaction takes place. They may be found in all decomposing

animal bodies; for example, "gamey" meat, stinking fish, shell-fish, and lobsters.

The bodies so far described, according to Mr. Wolfenden, are: 1, ptomaines, like atropin and hyoscyamin, which dilate the pupil and accelerate the heart; 2, a ptomaine, from decomposing yeast, which resembles strychnia; 3, a ptomaine resembling morphia in its chemical, but not in its physiological reactions; 4, a ptomaine agreeing chemically with delphinin; 5, a ptomaine resembling, chemically only, strychnia; 6, ptomaines resembling conine, parvolin, and collodin.

The following conclusions present succinctly the practical facts regarding the alkaloids under consideration:

First.—There are developed in the body, post mortem, poisons of an alkaloidal character, and which can be obtained also by decomposition of albumen, peptone, casein, muscle, brain, etc. Moreover, they seem to be present in some normal secretions (saliva and urine).

Second.—These cadaveric alkaloids may be mistaken, post mortem, for vegetal poisons administered with evil intent, but if the body be examined within from twenty-four to forty-eight hours after death, any alkaloid there found would be strong presumptive evidence of poison, and not ptomaine. After a couple of days it may be a matter of doubt.

Third.—There is no satisfactory test surely indicating the presence of a ptomaine. Physiological characters must be taken in conjunction with chemical tests.

Fourth.—Probably the production of ptomaines within the living body may be the pathological cause of many obscure conditions, especially those following on poisoning by bad food, such as stale fish, etc.

BEGGING FOR STUDENTS.

SOME very disagreeable disclosures have been brought to light recently in connection with one of the Louisville medical colleges. The *Louisville Medical News* publishes letters which show beyond a doubt that a certain college in that city has been sending out circular letters to medical students, or those intending to be such, asking them to come to Louisville and take a course in the favored college at a reduced rate.

What is still worse, evidence is shown by Dr. James E. Reeves, of West Virginia, that even the very illiterate are welcomed, and no questions as to previous education asked. Under Dr. Reeves' direction a veritable medical student sent as an answer to the circular letter a "made-up" effusion, of which the following is a part:

"WHEELING, W. VA., Aug. 18, '83.

"DOCT—

"One of mi Friends who is trying to be a Doct has got a letter from you which says your College is one of the Best College For Medical Teaching in America and that the Feas are cheaper than some other good Colleges and that sutes my circumstance for I am a very poor young man and no matter how much I may Know of Thery of Medicin I cant practice in W. Va. without a Deploma from a good College like the one you have in — you offerd to take mi Friend for \$50 dollars and you will do a poor young man a favor if you will take me at the same Rate for I have that much money I can pay you in cash as soon as I get there," etc., etc.

To which an answer came promptly back inviting the student to come right along.

We regret that such things should occur, for they force us to think that reform in medical education is moving on but slowly. It is, however, some consolation to know that the practices thus going on have been so promptly disclosed, and that public agitation will probably force the school to abandon them or to close up its doors. The censorship of the medical press has done much to check the abuses in medical education, and its influence grows more powerful each year. The profession at large demands honest colleges and an honest educational training of those who are to join its ranks. Our medical teachers are finding that this demand cannot be long ignored.

News of the Week.

SOCIETY FOR THE RELIEF OF THE WIDOWS AND ORPHANS OF MEDICAL MEN.—This Society held its forty-first annual meeting last week, when the following officers were elected: *President*—Dr. Isaac E. Taylor; *Treasurer*—Dr. John H. Hinton. Seven managers were also elected. The Treasurer's report showed that the Society numbers 140, of whom 92 are for life, and 42 annual subscribers. The number of benefactors living is 20, of whom 1 is a layman; 32 benefactors are dead, of which number 6 were laymen. The annual members pay \$10 initiation fee, and \$10 dues per year; the life members pay \$100. Benefactors pay \$150 or upward. Some of the latter have left large bequests to the organization. The total assets of the Society, September 19, 1883, amounted in value to \$143,447.93, all safely invested. Aid was extended during the past year to thirteen widows and four children of dead members. The amount disbursed for this purpose was \$4,251.50, and the indispensable expenses for printing, safe, clerk hire, stationery, etc., was \$213.38.

PROSECUTED FOR SELLING ADULTERATED DRUGS.—In the Municipal Court recently, Rust Bros. & Bird, wholesale druggists, were charged with selling adulterated drugs by the State Board of Health, Lunacy, and Charity. It is understood that this is only the first of a series of prosecutions of a similar character against large manufacturing drug firms. It is stated by the medical officer of the board that in a number of specimens of commonly used drugs obtained from various firms the percentage of the active principle has been found to be very much less than is called for by the United States Pharmacopœia. For instance, citrate of iron and quinine should contain twelve per cent. of quinine, yet its proportion has been found to be as small as $3\frac{7}{10}\%$ per cent. In tincture of opium, which should contain $1\frac{2}{10}\%$ per cent. of morphine, the proportion has in some cases run down to five-tenths of one per cent.

CENSUS OF THE MEDICAL SCHOOLS OF NEW YORK FOR THE PRESENT SEASON 1883-84.—The number of matriculants at the different schools in the city is about the same as that of last year. At the College of Physicians and Surgeons the number is over five hundred and forty-three; at Bellevue Hospital Medical College not quite

four hundred ; at the University Medical College about five hundred and fifty ; at the Woman's Medical College about fifty. The number of matriculants at the post-graduate schools varies, but has been not far from one hundred. The veterinary schools are well attended, there being over one hundred students in the two. The total number of students of medicine in the city this winter is between eighteen and nineteen hundred.

DR. D. W. YANDELL, of Louisville, has been elected honorary member of the Medical Society of London. We heartily congratulate Dr. Yandell upon this honor, which he entirely deserves.

THE HEALTH DEPARTMENT AND ADULTERATED TEAS.—The complaint in the suit of the New York Health Department against a firm in this city for selling adulterated teas was dismissed by Judge O'Gorman, of the Superior Court, last week. It was proven that the tea was extensively adulterated, but it was not shown that the adulterations were injurious to health, and on this ground the complaint was dismissed. The decision is an important one, as showing certain limitations which the present law puts upon the action of sanitary authorities. ■

DEATH OF DR. W. B. MCGUIRE.—Dr. McGuire, of this city, died last week, after a lingering illness. He was born in New York and graduated in medicine at the University Medical College in 1871. For some time thereafter he was connected with one of the clinical chairs in that College.

ACTINOMYCOSIS DISCOVERED IN AMERICAN CATTLE.—Dr. William T. Belfield, of Chicago, has made the important discovery that actinomycosis exists in American cattle. He was asked by the Commissioner of Health of Chicago to investigate a disease in cattle which has generally been known as "swell-head," and has been called by veterinarians cancer, sarcoma, etc. Five animals were examined by Dr. Belfield, and a very short study of the specimens under the microscope revealed the true nature of the disease. Actinomycosis was only recognized six years ago by Böllinger, of Munich, who announced that it was a parasitic disease due to the presence of a rapidly growing fungus. It has since been discovered in the hog and in man. It generally first attacks the jaws, and probably gains access to the deeper tissues through carious or defective teeth. It spreads into the tissues of the head, causing tumefactions, suppuration, finally, if unchecked, pyæmia, and death. It may gain the blood and be transferred to other parts of the body. This happens especially with man, upon whom the parasite acts most virulently. It is supposed that its source is the grain with which animals are fed. The disease is generally fatal, though prompt measures may check it. The meat of animals dying from actinomycosis is not of first quality. It is not, however, yet known that it is absolutely injurious. Thorough cooking, at any rate, destroys the parasite. Dr. Belfield's discovery is an important one, and should become promptly known to veterinarians and sanitary officials.

ENTERPRISING UNDERTAKERS.—It is rare, we are told, that any nationality exceeds the American in business activity and enterprise. We must yield the palm to the London undertakers, however. We do not think that

even in this much maligned city the business instincts of our mortuary artists would exhibit themselves as, according to the *Lancet*, has been done in England. That journal annotates as follows: "Medical men are from time to time insulted by the overtures made by enterprising undertakers with a view to obtaining their recommendation to the families of deceased persons ; but few proposals so unblushingly impudent as that recently made by a London undertaker to the members of the medical profession, by means of a lithographed letter, marked 'private and confidential,' are happily known to history. The tradesman who has not scrupled to issue this trade circular has the audacity to offer practitioners a commission ranging from five to twenty per cent. according to the amount expended on the funeral ; and to facilitate matters, he adds, 'It will not be necessary in any case for you to wait upon me with reference thereto [that is, the receipt of the commission], but simply to send a line to say you attended the deceased, as no inquiries will be made beyond this.' We call attention to the matter, at the request of several correspondents, to mark the sense of the profession at the insult it has received, and to deter this particular tradesman—and others—from repeating the affront."

SCIENCE A PEACE-MAKER.—It is pleasant, says the *British Medical Journal*, in these times of political squabbling and dishonorable jealousies, to see science step in and disperse national animosities as effectually as it removes vulgar errors and diffuses world-wide truth. On the sad occasion of the death of M. Thuillier, Herr Koch, Director of the German Cholera Commission, and all his colleagues, promptly expressed regret and sympathy, and also their desire to be useful. On his coffin they nailed laurel-wreaths. On the day of the funeral M. Koch officiated as a pall-bearer. This graceful act of humanity was feelingly appreciated by the members of the Pasteur Commission, who described it as "un hommage précieux et touchant." We confess that we cannot see anything so remarkable and touching in the above acts. M. Koch and his colleagues would simply have been brutes if they had done any less.

THE FIGHT AGAINST QUACKS IN MISSOURI has begun in Kansas City, by the Board of Health refusing to recognize the diploma of a certain graduate of the "Cincinnati Health School." The graduate in question applied to the courts for a mandamus to compel the Board to recognize this diploma. We are not yet informed of the issue.

A MEDICAL SOCIETY VS. A MEDICAL JOURNAL.—At the recent meeting of the District Medical Society at St. Joseph, according to the *Weekly Medical Review*, an attempt to boycott the St. Joseph *Medical Herald* was made. It seems that the *Herald* took occasion to criticise the action of the society in allowing members to bring personal quarrels before the society to the exclusion of scientific questions. In addition to this the *Herald* spoke rather decidedly on the propriety of giving an entire session of the society to a St. Louis medical man, who delivered a lecture on his own specialty. Resolutions censuring and condemning the *Herald* were offered, but were hardly read before a motion to table was carried. This action so enraged the champions of the

resolutions that they launched out in speeches more forcible than elegant, and finally the climax of disorder was reached when one of the members and the editor of the *Herald* came together. The scene became very lively for a while, but the members were at last induced to quiet down.

DR. BRADLEY S. McCABE, President of the Greene County (N. Y.) Medical Society, has been chosen to represent his county in the Assembly. The more of such men the better.

TESTIMONIAL TO MR. JONATHAN HUTCHINSON.—The students and graduates of the London Hospital have subscribed the sum of \$2,000 as a testimonial fund for Mr. Hutchinson. Fifteen hundred dollars of this has been set apart as a fund for a biennial prize essay on clinical surgery. The remainder was devoted to the purchase of a personal testimonial, which was formally presented to Mr. Hutchinson on November 29th.

DEATH OF DR. G. S. PFEIFFER.—Dr. Pfeiffer, of Camden, N. J., died at his residence in that place on November 28th, aged seventy-seven years. He was a gentleman of extensive scientific knowledge, speaking seven languages, and he had written several non-medical works. He was a member of the Historical Society of Pennsylvania.

THE MUSEUM OF HYGIENE AT WASHINGTON.—The Army Medical Department has already achieved a world-wide reputation for its work in medical bibliography, for its library and pathological museum. The Naval Medical Department soon bids fair to rival it in the direction of hygiene. It has already collected a library of over five thousand volumes, chiefly of works relating to sanitary science. Its museum of hygiene is growing and already contains two hundred and sixty-four exhibits. The American Public Health Association has made it its permanent repository. We are informed that the Surgeon-General requests contributions of articles, appliances, models, drawings, etc., illustrating improvements in food, water-supply, bedding, clothing, marine architecture, house and hospital construction and furniture; apparatus for heating, illuminating, ventilation, and removal of excreta and refuse; culinary, laundry, and bath facilities; appliances for physical culture and exercise; and whatever else tends to the preservation of health and the prevention of disease. The exhibits are properly credited by descriptive labels to the persons contributing them.

SANITARY CONDITION OF THE PUBLIC SCHOOLS.—The Health Commissioners have decided to expend \$6,000 in making the most needed improvements in the public schools, leaving the rest till next summer. But what about the health of the children in the meantime?

MONCK, THE BROOKLYN CHARLATAN AND FAITH HEALER, has been indicted and convicted of deception and malpractice. He had acquired an immense popularity among the women of Brooklyn, whom he treated for all kinds of diseases, and by most extraordinary methods.

A SOCIETY FOR HOSPITAL ADMINISTRATION.—An association is to be formed in London for the purpose of studying subjects connected with hospital administration. More definitely, the objects of the proposed association are, firstly, to facilitate the consideration and discussion

of matters connected with hospital management; and, where advisable, to take measures to further the decisions arrived at; and, secondly, to afford opportunities for the acquisition of a knowledge of hospital administration, both lay and medical. The association, moreover, proposes to afford facilities for the reading, discussion, and publication of approved papers; for the delivery of lectures, and for the holding of conferences on hospital administration, hospital management, medical relief, medical education in relation to hospitals, free and provident dispensaries, and other kindred subjects, and will found a library, consisting of works on hospital administration, construction, finance, and statistics.

YELLOW FEVER AT HAVANA.—Clean bills of health were issued, after inspection by Sanitary Inspector Burgess, to vessels from Havana bound to United States ports during the week ending November 17th: American steamer Hutchinson, for New Orleans; American steamer Niagara, for New York; British steamer Marco Aurelio, for New Orleans; Spanish steamer Santiago, for New Orleans; British steamer British Empire, for New York. Dr. Burgess states that the above-named vessels were all in the open bay and had not been to the wharf. In a letter to Surgeon-General Hamilton he says that at no time during the year has so large a proportion of sailing vessels suffered from yellow fever in the harbor at Havana as at the present, and that there are about seventy-five cases of the disease in the city, among them the recently appointed Captain-General, Castillo, who is now convalescing, having been attacked about two weeks ago. Total number of deaths from yellow fever during the week, 18.

YELLOW FEVER NEWS FROM MEXICO indicates that the disease still continues in the towns of Manzanillo and Acapulco, though rapidly disappearing. There is an epidemic of scarlet fever in Pueblo, which, Assistant Surgeon Main, of the Marine Hospital Service, states, gives more alarm than did yellow fever. Quarantine restrictions have been removed at Matamoras as well as at Brownsville, Texas. At the former city a large lagoon nearly surrounding the town has been drained, thereby causing much malarial fever. The news from Havana continues unfavorable, as the weather is so warm that yellow fever has had little or no check. There were twenty deaths for the week ending November 24th, and several infected vessels sailed for the ports of Savannah, Pensacola, New Orleans, and Charleston.

THE MEDICO-LEGAL SOCIETY.—The annual election of this Society, held December 5th, resulted as follows: President, Clark Bell, Esq. (third term); Vice-Presidents, Dr. R. O. Doremus and D. C. Calvin, Esq.; Secretary, L. P. Holme, Esq.; Treasurer, A. D. Hammersley, Esq.; Curator, Dr. A. H. Smith; Chemist, Professor C. A. Doremus.

THE ORTHOPÆDIC HOSPITAL AND DISPENSARY held its annual meeting December 5th. The report of the previous year shows the institution in a prosperous condition. Over fifteen hundred patients were treated, of whom four hundred and fifty were either entirely or partially cured. Fourteen beds were endowed for one year.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, November 14, 1883.

GEORGE F. SHRADY, M.D., PRESIDENT, IN THE CHAIR.

ABSCESS OF THE ANTRUM CAUSED BY AN EXTRA TOOTH.

DR. JOHN A. WYETH presented a tooth removed from the superior maxilla of a woman, twenty-six years of age, who came to him with trouble in the antrum of Highmore on the left side. She stated that *thirteen* years previously she had scarlet fever and measles, and since then had had painful sensation at times in the region of the antrum. In order to relieve the pain a dentist had been induced to extract a tooth, and through the opening thus made a discharge of pus occurred, and the purulent discharge had continued in variable quantity, but never ceasing entirely, for seven or eight years subsequently. Dr. Wyeth extracted two more teeth from the same side, and gave free drainage to the antrum. He also removed some particles of bone, and through the opening a tooth was discharged which, according to count, was an extra development in the superior maxilla. It had grown inward, and finally dropped into the antrum, where it acted like a foreign body. The discharge ceased for a time after the tooth came away, but it had recurred and Dr. Wyeth thought that dead bone yet remained, which he proposed to remove entirely by opening the antrum more freely. He regarded the cause as a very unusual one for the formation of pus in the antrum.

DR. GEO. L. PEABODY presented specimens illustrating

EMBOLISM OF THE BASILAR ARTERY—EXTENSIVE VALVULAR DISEASE OF THE HEART, WITH HYPERTROPHY AND DILATION—PERICARDITIS—DIFFUSE NEPHRITIS

J. C—, twenty-two years of age, United States, single, mechanic, was admitted to the New York Hospital July 7, 1883. His mother died of heart disease; the rest of his family are alive and well. He had rheumatism two years ago, but subsequent to that time he remained pretty well until ten weeks ago, since which date he has had dyspnoea, cardiac palpitation, swelling of the feet, headache, and tinnitus aurium. These symptoms have steadily increased in severity, and now he can hardly walk about, and is very short of breath. He gives no history of urinary symptoms. He gives a well-alcoholic history. He had at this time fluid in both marked pleural cavities and in his peritoneal cavity, and also oedema of the lower extremities. His temperature was normal; his pulse was irregular; the apex beat diffused, and a loud systolic murmur was heard over the apex. His urine gave the following record: specific gravity, 1.014, pale, acid, large amount of albumen, granular and hyaline casts; thirty ounces passed per diem. He was treated after various routine methods, with some improvement. His urine increased greatly in amount. After two weeks' hospital residence the character of the murmur changed. Instead of being a *loud systolic* murmur it became a *loud musical murmur heard with both sounds* of the heart. He improved from time to time, passed more urine, slept better, ate better, was able to go about, etc., and then he got worse again, as such subjects do.

The oedema became so great in his foreskin that puncture was resorted to with relief. His abdomen was tapped, between September 6th and October 20th, seven times, and clear serum withdrawn on each occasion, varying in amount from sixty to two hundred and sixty ounces. About the middle of October he complained of much pain in the precordial region.

On October 20th he became very silly without warning, restless, resisting efforts on the part of attendants to keep him in bed, refusing to speak at all, and merely staring

fixedly at any one who addressed him. His heart's action increased in irregularity; he had diarrhoea; he lost control over his bladder and rectum. For the two following days his restlessness increased, and he was inclined to be noisy. Anasarca became excessive. In the evening of October 22d he became very noisy and violent. Hypodermic injections of morphia and hyoscyamia were ineffectual in controlling him, and it became necessary to put him in a strait-jacket and remove him from the ward. His temperature did not rise above normal. He shouted and struggled all night. On the following morning he resisted all efforts at medication or nourishment, and it became necessary to feed him by means of a stomach-tube.

On October 24th he became less noisy, but his general condition remained without change. His urine diminished in amount to fourteen ounces, but it became possible to return him to his ward and remove his strait-jacket. On this evening he suddenly became very quiet; sank into a condition of stupor. At 11 P.M. pulmonary oedema developed, which was temporarily relieved by cupping, but he died at twenty minutes after midnight, October 25th.

DR. PEABODY presented a portion of the base of the brain, including the pons with the basilar artery attached, and also the heart.

Autopsy.—Brain: Just behind the anterior border of the pons the basilar artery was seen to be plugged by a firm clot, whose centre was partly decolorized. The entire lumen of the vessel was obliterated and the artery was somewhat distended at this point. The brain was everywhere somewhat softened by post-mortem change, but its structure was nowhere pathologically altered. The lesion spoke for itself and needed no further description. The peritoneum contained two litres of clear serum. There was no evidence of peritonitis. The height of the diaphragm on the left side was at a level with the sixth rib; on the right side, with the fifth rib. The heart was large. Both ventricles were markedly dilated. The endocardium of the left ventricle was much thickened. The attached borders of the aortic cusps were also thickened. But the chief lesion of interest was in the mitral valve; both of its cusps were markedly thickened and stiffened, and their surfaces were very rough. Upon these roughened surfaces in the fresh state one could see many little vegetations attached, some of fibrin, others, older, of connective tissue. It was not difficult to imagine these as the origin of numerous emboli. One of the chordæ tendinæ had been eroded and now terminated free in the cavity of the ventricle, and had upon its extremity a large mass of connective tissue and fibrin. The lungs were both retracted and were everywhere adherent to the chest-wall. Over the posterior and upper surface of the lower lobe of the left lung was a layer of recently exuded lymph, three inches in diameter and irregularly circular in shape. Corresponding with this area was the base of a hemorrhagic infarction of dark red color and about the consistency of a hepatized lung. The right lung was oedematous and congested, and exhibited the lesion known as brown induration. The spleen was large and had an old decolorized infarction in the upper border. The capsules of both kidneys were adherent; surfaces of both were granular. They had the peculiar firm consistency of so-called "heart kidneys." The cortex was thin, its workings indistinct, and its surface presented the scars of several old infarctions. The liver was large. The centres of the acini were pigmented and their peripheries were anæmic.

Remarks.—There are several points of interest in this case. The lodgment of an embolus in the basilar artery is unusual, and it seems strange that a plug which has passed through a small vessel should lodge in a larger one. The patient was young, and there is no change in his arteries such as might have suggested a local cause for the arrest of the embolus. The stoppage of so large a vessel would, of course, be attended by serious interference with the nutrition of the parts supplied

by it, were it not for the abundant anastomosis. In this case there was no softening, but there probably was some temporary disturbance of nutrition when the functional cerebral disturbances occurred, as noted in the history. The color of the embolus led me to suppose that it had existed only a few days, and it seems fair to infer that its lodgment coincided with the man's delirium. On the other hand, the possibility of the dependence of the cerebral symptoms upon the kidney lesion must be admitted.

Referring to the heart, the change in the character of the mitral murmur is very interesting in connection with the lesion of a tendinous cord that you see here. Unfortunately, we have no means of dating exactly the occurrence of this lesion.

DR. WYETH asked Dr. Peabody what he regarded as the immediate cause of death.

DR. PEABODY answered that with such a number of diseases, any one of which was incurable, it was difficult to determine what the immediate cause of death was.

DR. WYETH said the reason why he asked the question was because he had already presented two specimens of embolism of the basilar artery, and in each instance the immediate cause of death was attributed to disturbance of the nutrition of the pons and medulla. There had been in all about twelve cases reported, and in each the immediate cause of death had been assigned to malnutrition of the pons and medulla. Dr. Wyeth had proposed to ligate both vertebral arteries in two cases of epilepsy, acting upon the theory that miliary aneurism of the medulla and pons was the most constant lesion in that disease, but at about that time the two patients died from the bodies of whom he obtained the specimens of aneurism of the basilar artery he had presented, and he was deterred from performing the operation.

Since then, Dr. Alexander, of Liverpool, has performed the operation in ten or eleven cases of epilepsy, sometimes ligating one and sometimes both vertebral arteries, and in all the cases the patients had recovered from the convulsions. Dr. Wyeth also had tied one vertebral and the patient did not die of disturbance of the nutrition of the pons and medulla, but of pneumonia four days subsequent to the operation.

IVORY EXOSTOSIS FROM THE ETHMOID CELLS.

DR. H. KNAPP presented a specimen with the following history. He removed it from a woman forty-five years of age, apparently in robust health, except that she had suffered from nasal polypi for fourteen years. Twelve years ago these polypi were, for the first time, removed. In the course of years four more such operations had been performed, the last one being about two years ago, after which they grew much more rapidly than ever, and six weeks ago both nostrils were occupied, the left almost completely and the right to a considerable extent. There was at the inner side of the left orbit a hard tumor, apparently about the size of a filbert, which crowded the eyeball toward the temple and somewhat forward, produced a slight degree of congestion and folding of the retina, but vision was still good. There was no evidence of cerebral disease. Dr. Knapp advised removal of the polypi slowly, which was done by Dr. R. P. Lincoln, who extended the operations over four or five weeks. The growths were soft and to some extent fibrous. Dr. Knapp thought that the hard orbital tumor, felt through the skin, was either an osteoma or the bony shell of the expanded ethmoid cells, which it would be easy to break down, and so allow of the removal of the remainder of the polypi from that side. He was quite confident that the remaining polypi could not be removed by either the anterior or posterior nasal passages. So he believed that opening the lateral part of the nose by removing the bony tumor would give easy access to the polypi. The hard tumor was laid bare by an incision carried down to the periosteum, and then with the end of a small chisel he removed all the periosteum from the nodular surface

of the bony growth. When this was completed he seized one of the projecting parts of the growth with a strong bone forceps and soon found that it extended through the os planum into the ethmoid cells, and also was fastened to the nasal septum. Without the exertion of very much force, however, it was removed, and with only the slightest amount of injury to the tissues. He did not expect that any serious reaction would follow the operation. The left frontal sinus was also opened. It contained a large gelatinous polypus, which was removed. He also very carefully explored the frontal sinus with a sharp spoon, but detected neither carious bone nor other tumors. The external wound was closed completely, as free drainage could occur from the inside.

The patient did perfectly well during the first twenty-four hours, but then complained of headache, which was followed by somnolency that increased, accompanied by rapid pulse and marked elevation of temperature (104.5° F.). She died comatose on the fourth day after the operation. The autopsy was made by Drs. Prudden, Lincoln, and himself, and he asked Dr. Prudden to demonstrate the condition of the brain.

DR. T. MITCHELL PRUDDEN said the brain had been frozen, and therefore its natural color had been changed. The dura mater was perfectly normal. On removing it, the pia mater covering the right side of the concavity of brain was found completely infiltrated with pus, especially along the large vessels. The meshes of the pia, as well as the space beneath it, were so filled with serum that the convolutions were considerably flattened. Upon the side of the operation (the left) there was much less purulent infiltration than upon the other, but it was well marked in a zone about an inch wide extending along the course of the longitudinal fissure. There was some infiltration of purulent matter along the vessels at the base of the brain. The brain tissue was hyperemic. The fluid in the lateral ventricles was somewhat increased and stained red. There was no lesion of the inner table of the skull. There was no evidence of direct transmission of the inflammatory process from without inward.

DR. KNAPP also exhibited a portion of the skull, removed so as to expose the ethmoid cells, which he found plugged with polypi. It also revealed that at the site of the operation there was no irritation or inflammation. The external wound had healed by first intention. The eyeball was healthy. The sphenoid cells also were plugged; the right with a clot, probably from the operation, and polypi, while the left was completely filled with cheesy pus and its communication with the ethmoid cells was obstructed by polypi. The bulk of the tumor had an ivory consistence, its centre was somewhat cancellous.

Dr. Knapp believed that the proper way to remove these tumors was by the subperiosteal enucleation. He regarded the fatal result in this case as due not to the operation, but to the diseased condition of the ethmoid and sphenoid cells, and that the operation only rendered active a condition which would have inevitably sooner or later terminated fatally.

With regard to the treatment of nasal polypi, no human hand could have removed them in this case. He urged that if the deep-seated of these tumors are to be dealt with at all they should be removed *early*; the same rule applied to exostoses.

VESICULAR HYDATID MOLE

DR. C. HEITZMAN presented a specimen, for which he was indebted to the kindness of Dr. Danforth. As is usual, the patient had profuse hemorrhage, and as always occurs, the ovum was destroyed. He accepted Virchow's view concerning the character of the growth—namely, that it is a myxomatous degeneration of the villousities of the chorion.

DR. H. J. GARRIGUES recalled an article written by Maslowsky, a Russian physician, who had found phlebitis of the umbilical vein with formation of thrombi on the walls and consequent diminution of lumen. He takes

this to be the origin of the evil, and the changes in the chorion, decidua, and fœtus to be secondary. In consequence of the damming up of the blood the vessels persist in those villi in which normally they are destroyed, those outside of the placenta, and a transudation takes place into the stroma of the villi. Later thrombi are formed in the capillaries of the villi, and they undergo a regressive change and the vessels are destroyed. The decidua showed chronic inflammation, namely, connective tissue instead of the characteristic decidua cells, and extravasation. The fœtus was well formed, but much too small for the period of development (*Centralblatt für Gynäkologie*, 1882).

Dr. Garrigues also remarked that the fœtus did not die in all cases, for a celebrated obstetrician, Hohl, was said to have been developed in an ovum part of which formed a hydatid mole.

DISCHARGE OF SEROUS AND BLOODY FLUID FROM THE NIPPLE—CARCINOMA OF THE BREAST.

DR. A. G. GERSTER presented a very small nodule removed, together with the breast, from a woman sixty-one years of age, who had borne nine children, all of whom she had nursed. Her nipples used to be sore occasionally, but not frequently, and she never had a mammary abscess or any serious inflammation of the gland tissue of either breast. Dr. Gerster saw her first in the latter part of May, when she applied for relief from a serous and bloody discharge from the nipple. A most careful examination of the breast failed to reveal any tumor proper. The axillary glands were normal. He expressed the suspicion that a malignant process was beginning, although the skin was apparently healthy and the nipple was not retracted. Being absent from the city he did not have opportunity to examine the patient again until the first of October, but was told that the aspect of the case had not changed. At that time, however, he was surprised to find a large mass of hard glands in the axillary space, requiring very careful dissection, on account of its close adherence to the sheath of the axillary vein. After removal of the breast a very small non-incapsulated nodule of cancerous tissue was found in its outer lower quadrant. He presented the specimen on account of this peculiar fact, observed in three cases, namely: with a very small but infiltrated breast tumor he had found a disproportionately extensive involvement of the axillary glands, which rendered an otherwise simple operation rather difficult, and made the prognosis a very doubtful one.

DR. HEITZMAN said he had in his collection a specimen of primary cancer of the axillary glands. Recently Paget had directed attention to certain forms of eczematous affection of the nipple followed by cancer in which also the lymphatics are involved very early. He thought Dr. Gerster's case resembled this class.

DR. WYLIE remarked that in some cases tender spots could be made out where no enlargement could be felt.

DR. GERSTER further stated that he considered the removal in one mass of the entire contents of the axillary space—fat, glands and all—to be imperative, since the smaller glandular bodies of about the size of a hempseed cannot be felt through the integument and fascia, and can be made out only with difficulty even after the fascia was opened. Where the infiltration of the axillary glands can be distinguished through the integuments, the involvement is very extensive indeed, and a difficult dissection may be expected.

STRUMOUS ARTHRITIS OF THE KNEE-JOINT—AMPUTATION.

Dr. Gerster also presented a part of one of the lower extremities of a child two years old, removed by amputation, and with the following history. The patient had suffered from strumous disease of the knee-joint for some time, when it was suddenly taken with high fever, and the family attendant said it was due to a sprain and

ordered poultices, the result of which was an extension of the phlegmonous inflammation up and down the limb, with perforation of the capsule. The child's life seemed to be in imminent danger, and amputation was immediately performed. Dr. Gerster was compelled to operate through inflamed tissues. A strong solution of the bichloride of mercury was used, 1 to 500, and although a part of the long anterior flap necrosed, a considerable portion of the amputation-wound healed by first intention, even parts which had been the seat of an active phlegmonous process.

DR. HEITZMAN remarked that, before the time of antiseptic treatment, it was known to surgeons that even tissues which were the seat of strumous inflammation were prone to primary union after either resection or amputation. He did not know as Dr. Gerster would insist that the favorable result in his case was due to the use of the strong solution of the sublimate.

DR. GERSTER said he could not help believing that the result was due to the use of the sublimate solution, as he had amputated under similar circumstances several times, and had seen new phlegmonous conditions develop. It was an old and established principle in surgery to operate in healthy tissues, and that when surgeons were obliged to operate in tissues the seat of active septic conditions, the peculiar condition was apt to invade other parts, and very frequently terminate fatally.

CANCER OF THE ŒSOPHAGUS.

DR. HENSCHEL presented a specimen removed from the body of a man, aged seventy-three, who for some time suffered from dyspeptic symptoms, with distressing eructations, and finally came under Dr. Henschel's care, who induced him to take fluid food only, which he did for a few months, with so much benefit that he gained considerably in weight. The former symptoms then returning with ejection of the fluid food, Dr. Henschel introduced an ordinary œsophageal bougie, and found an obstruction which he was unable to pass. About three months later Dr. Janeway saw the patient with him, and at that time swallowing could not be heard below the second dorsal vertebra. The patient had then lost nearly seventy pounds in weight. Some days afterward Dr. Henschel again introduced the bougie, for the purpose of ascertaining, if possible, the exact situation of the obstruction, and with the view to dilatation.

Two days subsequently the patient spat up two large quantities of blood. Soon after that his condition began to improve, and he took milk freely, but the dulness to the right of the sternum increased. He gained in weight twenty-five pounds and remained quite comfortable until recently. On October 29th an attack of pleurisy developed over the lower lobe of the right lung, but the symptoms subsided within a few days and he was up and quite cheerful when, on November 4th, bronchitis began. On November 5th a gurgling was heard at about the middle of the lower lobe, as though the lung was breaking down. On the following day typhoid symptoms developed, the patient became unconscious, and on the next day that side of the chest was completely filled with fluid. The patient died on November 9th.

Autopsy seven hours after death revealed constriction of the œsophagus by carcinoma, which had invaded the right lung, and the pleural cavity was completely filled with fluid, which had an odor as if from the stomach. The kidneys were fatty, although during life neither albumen nor casts were detected in the urine.

DR. PEABODY said it was interesting to find an opening through the œsophagus communicating with the pleural cavity, with partly digested pleura and lung. There had been regurgitation of the contents of the stomach, and this digestion had taken place after death, probably.

(To be continued.)

Correspondence.

OUR PARIS LETTER.

(From our own Correspondent.)

THE LONGEVITY OF ACTIVE SCIENTIFIC WORKERS—WORK IN OLD AGE AS A PREVENTIVE OF DECAY—RUMINATION AS A SYMPTOM OF INSANITY—COMPARISON OF MENTAL ACTIVITY IN BOYS AND GIRLS—THE MORTALITY OF TYPHOID—ETIOLOGY OF TYPHUS—THE THEORY ABOUT MICROBES.

PARIS, November 9, 1883.

M. BENOISTON, of Châteauneuf, published some years ago a curious article on longevity among the members of the Institute. Unfortunately the work has not been continued. But in the "Annuaire de l'Institut," for 1883, we still find a great many long-lived members. The following is a list of the senior members whose elections to the Institute date prior to 1840: Chevreul, of the Academy of Sciences, elected in 1826, entered his ninety-eighth year on August 31st last; Jean Baptiste Dumas, of the same academy, was elected in 1832, now aged eighty-three; Mignet, of the Academy of Moral and Political Sciences, elected in 1832, now aged eighty-seven; Charles Lucas, of the same academy, elected in 1836, now aged eighty; Henri Milne-Edwards, of the Academy of Sciences, elected in 1838, now aged eighty-three; Augustin Dumont, of the Academy of the Beaux-Arts, elected in 1838, now aged eighty-two; Barthélemy Saint-Hilaire, of the Academy of Political and Moral Sciences, elected in 1839, now aged seventy-eight.

M. Bouchardat, Professor of Hygiene at the Paris Faculty of Medicine, protested in strong terms, at a recent lecture, against the advice given by some hygienists who recommend almost complete rest to the aged, in the following terms: "I protest against the oft-repeated adage that old age is the age of rest. This sentence has led to a very great error in hygiene. The regular general exercise of all the organs of nutrition and of locomotion is necessary to persons of all ages.

"The greatest attention on this point is all the more necessary that the tendency to rest brings on a gradual diminution of the strength. If the old man does not resist, his strength will visibly and progressively diminish, and the few days that he may have to live may be transformed into so many hours. In proof that regular daily exercise is beneficial to the aged, one has only to observe the results in some of the handsomest old men, who take little or no rest. Moderate exercise, particularly walking, should be the leading precept of the hygiene of the aged, without which longevity is impossible." Professor Bouchardat also recommends that old people should maintain their intellectual faculties, or otherwise they would get into a state of incurable torpor.

At a meeting of the Société des Sciences, Dr. Bouchaud, of Lille, drew the attention of the society of that city to a pathological condition more common in the insane than is generally believed, viz., rumination. At the asylum of Lommelet there were fourteen patients that ruminated, eleven among the idiots, of whom there were about a hundred, and three among the other five hundred and seventy inmates of the asylum. Several of these patients were reported to have ruminated long before they presented any signs of insanity. This symptom must therefore be considered of some importance whenever such cases present themselves.

In an interesting work on the studies of children, it has been brought to notice that in a large establishment containing about six hundred children, half girls, half boys, it was remarked that the girls furnished industrially work superior to that of the boys. At each periodical inspection it was also remarked with some surprise that they were mentally more alert, more developed. The

following was the explanation given for the difference between the two sexes: The girls were not so assiduous at their studies, for which they devoted only eighteen hours a week, the days for working at the establishment alternating with those at the school. The boys, on the contrary, devoted thirty-six hours a week at the school. To remedy this difference, the boys were submitted to the same rules as the girls, and the result obtained was as satisfactory.

The Paris Society for the Protection of Animals has submitted a petition to the Chamber of Deputies, requesting that bull-fights should be put a stop to, as being contrary to the principles of a civilized people, as exercising a deplorable influence on the delicacy of sentiment in the women and children, and often causing disturbances and serious accidents.

Dr. Worms, member of the Council of Hygiene of the City of Paris, lately drew up a report on the mortality caused by typhoid fever during the past four years. In 1879 there were 1,110 deaths; in 1880, 2,120; in 1881, 2,121; in 1882, 3,403. Dr. Worms remarks that in taking into account the increase of the population, the mortality from typhoid fever was fifty per cent. greater than it had been the fifteen preceding years.

Professor Bouchardat does not believe in microbes, at least, so far as they are concerned in the genesis of parasitic or contagious maladies. At the last meeting of the Academy of Medicine, the learned professor developed the subject, and gave in support of his theory the etiology of typhus fever. The following are the conclusions of his communication: 1. The parasite of typhus fever does not exist everywhere. 2. They originate by the transformation of normal organites (M. Bouchardat applies the term organites, the elementary figured elements which enter into the constitution of liquids or solids of the divers organs of an animal), following the debility arising from the continuation of famine or of typhigenetic affections. 3. The parasite, in evolving from the bodies of the famished, or from patients attacked with typhigenetic affections, is at its maximum strength; it does not propagate itself at a distance; it is very dangerous for those who approach patients suffering from typhus; the danger increases with the number of patients. 4. The parasite modifies itself in its nocuity, in its mode of action on the human economy, by a succession of transmissions, as it becomes definitely extinct. Professor Bouchardat adds that one ought to avoid, above all, to crowd patients, such as victims of famine, or those attacked by typhigenetic affections. The physicians, sisters, and nurses ought to take the greatest precaution against the danger that the parasite subjects them to, and these precautions should be taken as well during the night as during the day. One of the most imperious duties of a government is to prevent famine in all the regions that it governs. In conclusion, the hygiene of typhus has a history assured when it is founded on the notions furnished by clinical observations on the genesis and propagation of the parasite. No useful indication results from the hypothesis that this parasite exists everywhere. Everything is hidden and obscure with the Pasteurian theory of the existence of the parasite everywhere; all is easily explained, on the contrary, in admitting that the patients are the foci of the genesis and propagation of the parasite.

Whatever may come of M. Pasteur's theories about microbes, it may be observed that the lamented death of Dr. Thuillier, one of the French cholera mission to Egypt, would seem to be a flagrant contradiction of those theories, as well as of the absurd notions propounded by Dr. Burq on the microbicidal influence of copper, as we learn from the statement made by the surviving members that Dr. Thuillier, not only implicitly carried out the instructions given by M. Pasteur for their protection, but he was the only one of the mission that had saturated himself with copper before setting out for Egypt.

THE CHANCES OF THE YOUNG PRACTITIONER AS AFFECTED BY THE ADVICE GRATIS AND SMALL FEE SYSTEMS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: It was with a feeling of gratitude, shared, I am convinced, by many of my young *confrères*, that I read your editorial headed "The Chances of the Young Practitioner as Affected by the 'Advice Gratis' and Small Fee Systems."

There have been occasionally sporadic denouncements of the injustice done, especially the younger practitioners in this city, through the misapplication of medical charity, but everybody went to sleep again on the subject after such a feeble effort.

My only reason for asking a little of your valuable space is in the interest of our profession, which in this city is verily going to seed under the present *régime*. I hope that these few lines of a poor advocate may stimulate better talent among our young practitioners to do something for themselves in the way of agitating the means of bettering their condition.

It is, to a very great extent, our own fault that free clinics are so numerous, for most of the workers are young men. The great majority of us think it an honor to be attached to Professor N. N. as thirty-second junior assistant. The former gets the renown and free advertisement, while we get the drudgery and the doubtful benefit of figuring in multitudinous advertisements of a free clinic. Now, the dispensary doctor is a title looked on by the majority of people as a title of incompetency, as though such a physician had not totally absolved his curriculum of study, and is glad enough to give his services gratis in consideration of the variety of diseases to be seen and studied by him.

I hope the young practitioners of this city will keep on agitating this matter, now that it has been fairly started in your widespread journal, and bring it up persistently again and again, until either the Great Moguls of the medical profession in this city will find a remnant of the justice and fair play due their former disciples left in their consciences, feel ashamed of their grasping avarice, and turn away people in comfortable circumstances; or, what is perhaps easier to bring about, that some protective means be suggested by the younger members, either as a society or by individual agitation, against *indiscriminate* almsgiving in our dispensaries, polyclinics, and especially our colleges. This will have to be done sooner or later, and I think the time is at hand to make some earnest efforts for correcting this evil.

It is imperatively demanded by the large strides that these institutions are making every year, under the guise of philanthropy and charity, as it is put, not only toward the poor of the city, but also as an act of charity toward graduates and practitioners, who, it is said, could not otherwise keep up with the times, for want of clinical material and opportunity. This latter proposition will seem to any unprejudiced thinker as absurd. These gentlemen will always find plenty of worthy poor wherever they be located, whom they can treat gratis to their heart's content.

In unity there is strength. We are the majority. All we need is a few firm and intrepid leaders. Who will lead?

ONE OF THEM.

DULNESS OF HEARING IN TYPHOID FEVER.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In reading carefully the very instructive and interesting paper of Professor Delafield, recently published in the columns of your paper, entitled "Typhoid Fever in New York City," I am struck with the absence of one symptom in the one hundred and two cases he has so carefully collated, viz., dulness of hearing.

In all the typhoid patients it has been my privilege to treat, it has been present in all but one. This exception was a very mild case in which the temperature was

normal or subnormal nearly the whole time, and the patient was bright and natural in appearance.

So common have I found this symptom, that in those atypical cases where I was in doubt as to the nature of the disease for the first week, the sudden appearance of partial deafness has made it clear to me that I had a case of typhoid fever to deal with, and the subsequent course of the disease has proven that I was correct.

Whether or not dulness of hearing is often seen in the ordinary malarial fevers that run a course of several days, I am not able to say. Certain it is, that living in a malarial district and having such cases nearly all the time to treat, I do not call to mind one instance where this symptom appeared. Of course, I exclude such cases where deafness has followed the giving of large doses of the cinchona salts.

Now, in turning to distinguished authors and teachers, I find that most of those I have had opportunity to consult mention impaired hearing as one of the symptoms of typhoid fever, but not with the same degree of emphasis. Niemeyer says: "In the second week of the disease the complaints of pain in the head and limbs cease, but the dizziness becomes worse and the noises in the ears are accompanied by deafness."

Da Costa says: "Early in the disease ringing in the ears and dulness of hearing is encountered."

In "Reynolds' System of Medicine" the author of the article on typhoid fever says nothing of deafness, but Dr. Reynolds inserts in brackets, "dulness of hearing is almost invariably present."

Dr. Alonzo Clark says: "After the first week hearing is lessened, not absolute deafness, and just before deafness ringing in the ears."

Dr. James C. Wilson, in his book on "The Continued Fevers" in Wood's Library of 1881, says: "Deafness is very common. . . . It commonly appears toward the end of the second week."

None of the authorities above quoted give the relative frequency of this symptom, except Wilson, who says: "Deafness is very common." But all of them that are at all definite place the commencement of the symptom in the second week, or after the first week.

It is possible to diagnose a typical case of typhoid fever a few hours after the initial chill or chills, but as in these days of atypical diseases we often have to tell our patients that we will have to wait awhile before deciding as to the nature of the malady, it therefore behooves us to note carefully whether there is any one symptom more constant than others in such a dreadful disease, in the minds of the laity, as typhoid fever.

In my own experience this symptom has appeared somewhere in the second week, never in the first, and its disappearance has always been the commencement of the patient's improvement.

If none of those one hundred and two cases of Professor Delafield's exhibited deafness during the second week of the disease, or only a small proportion of them, then I will have to admit that my experience has been too limited to furnish me any data from which to draw conclusions.

Respectfully, E. D. COONBY, M.D.

MARINERS' HARBOR, STATEN ISLAND,
November 27, 1883.

A FEW WORDS ABOUT THE YELLOWSTONE NATIONAL PARK.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR: The Yellowstone National Park is wonderful—nothing more, and very surely nothing less. All who have been privileged to visit it will admit this cardinal fact of its existence. But it is not the kind of wonderland for fairies fit to dwell in, unless, indeed, those beings had first learned to survive a twofold ordeal, consisting in alternate congelation by nocturnal cold that would do credit to the North Pole, and diurnal evaporation through heat that the Equator might feel proud of.

As for your ordinary specimen of frail humanity, it

seldom persists in feeling serenely comfortable while experiencing the intense climatic variations that this park affords. In fact, a common mortal might there be apt to suddenly lay an overweening stress on his common mortality. He might, for instance, more or less silently melt away, or freeze solid, or at any rate perish after some fashion more deserving of professional consideration. But, all the same, it is a glorious wonderland, is this great park. The chief wonder, however, is this, that in spite of the perpetual influx of conscientious visitors, the wonders are still there.

So, too, is most of the land. The missing portions have been carried away by the enterprising geologist—a strange disease that erupts sporadically in this region. But let us be consoled. The Government has already appointed a scientific commission to fully investigate that dreadful plague. And when the Government appoints a commission—but let that pass.

The typical Yellowstone wonder is a rather shy institution. You can win it, however, by judicious and persistent wooing; and when at length you have succeeded in your endeavors, you find that you have secured a much bigger wonder than you bargained for—an intermittent geyser, for instance, that throws, playfully, high up into the air several lakes a minute, either clear lakes or muddy ones. It makes an ipecac-prescribing man feel almost small by comparison to witness such powerful results. Nature is, after all, a great physician—a model instructor. Only to think of the immense *vis emeticatrix nature*, here so plainly visible!

Or if you fail to capture a spouting geyser, very likely you will find some mammoth hot springs, steaming, gurgling, bubbling, boiling, with sulphurous water trickling down over the sides of great natural basins. Or if neither geyser nor hot spring, a grotesque formation, that plainly tells of exhausted spout or primal volcanic outburst. Indeed, almost at every step you are thus confronted with the remnants of former elemental chaos, or the intact relics of past upheavals. There is but one drawback to a comfortable revelling in these and many other unrivalled sights. The wonders, as already intimated, are not easily accessible. However, this may soon be changed. Time, occasionally stimulated by congressional appropriations, will do wonders with this wonderland.

But in all earnestness some means might be devised to develop, protect, and make easier of access the great natural beauties and resources of this extraordinary region. For example, there may reside in its countless hot springs and sparkling wells medicinal virtues of high value, that might prove beneficial or curative in many obstinate diseases. But as yet we possess absolutely no trustworthy information concerning them. A beginning in the right direction has, however, now been made. Professor Hoffmann, of Berlin, the well-known chemist, has secured samples of many of these springs and waters, so that we may soon expect to have made public the results of reliable analyses.

The Mammoth Hot Springs Hotel, prettily located at the entrance to the park, must be classed with the daring enterprises of American pluck. It resembles the huge caravansaries, so called, of Saratoga, Long Branch, or Coney Island. The bill of fare is quite elaborate, the rooms are large and good, the service is satisfactory. One weak, or rather strong point, your correspondent detected in the shape of an everlasting India-rubber cow. This extraordinary animal, being properly sliced and broiled, was served by dignified and solemn waiters as game. They called it elk-steak or mountain sheep fillet. But the guests only wrestled with it, they could not chew it. It was an exasperating Yellowstone wonder.

From this great hotel as a starting-point you can travel on horseback or in vehicle through the park for days and days, in pursuit of various wonders. The writer was fortunate. He procured a pony slightly handicapped with a somewhat Mexican saddle. He immediately bounded

off with unbounded enthusiasm, apparently shared by the steed, a noble animal, that galloped up and down the steepest hills as though winged with speed. Presently he was all aglow with the inspiring conviction that such powerful equestrianism had been rarely equalled, and certainly never excelled. It must have been a latent talent hitherto submerged in excessive medical erudition. Now, when opportunity offered, it at once asserted itself. At any rate, here was a flattering and pleasant reflection, and it endured just ten miles. Then the proud certainty that, after all, it only depends upon the rider, weakened a little. The next five miles it weakened a good deal more. Then it weakened still more. And it must be confessed, for the last ten miles, logic, philosophy, and cold reason compelled the humiliating admission that, after all, it all depends upon the horse.

As for those who had selected wagons, they insisted that these vehicles were discovered from the very start to be but cunningly devised apparatus for the creation of blinding dust and promiscuous torture. The day was in all respects a memorable one, however.

We had left the Mammoth Hot Springs Hotel late in the morning, and reached our first day's halting-place, a singularly impressive spot, early in the afternoon. It was but ten minutes' walk from the Norris Geyser Basin, which your correspondent will not attempt to describe. Mr. Winsor's guide-book does ample justice to its many wonderful and striking features. In fact, the writer wishes to here express his indebtedness to the two guide-books of that author, for much suggestive and valuable information concerning the entire region traversed during this trip. The spot just mentioned, where tents had been pitched for our accommodation, was situated on a gentle slope wooded with fir and pine trees. Below was a placid valley, cut by a clear stream winding its rapid course plashingly along, eager for union with the Yellowstone River. Around all an odd frame-work of distant snow-clad mountains completed an attractive picture, here barely outlined.

Gradually, under the soothing influence of a hearty meal and sufficient rest, the depressing effects of our long ride began to wear off. The sun was scarcely set, and already round about us the shadows quickly deepened into encircling darkness. Now a huge fire was kindled, fed by crackling boughs and fallen pine-trees. Its flickering glare strangely illuminated a wide circuit. In fitful gusts the air blew chilly through the camp, forcing the flames heavenward in sudden angry leaps. An expectancy of snow was in the atmosphere.

The company were soon attracted to the fire, disposing themselves in various groups around this centre of grateful warmth. Perhaps most of them were quite unconscious of the remarkable and highly picturesque effect thus produced. There they stood, sat, or lounged in various attitudes of contemplative repose. Members of the British Parliament were there, ambassadors, several ladies, distinguished Germans, authors, statesmen, the inevitable American colonel, and others, representing foreign or native intelligence, wealth, and refinement. Never before in the history of that region was such an assembly seen gathered about a blazing camp-fire. Beyond them, and to one side of the fire, in striking contrast with these gentler folk, the drivers had assembled. The brightness of the flames lit up the weather-beaten, sun-tanned faces of these gaunt, strangely clothed men. They smoked and chatted in grim contentment, looking for all the world like gypsy brigands on a frolic. Their forms seemed sharply etched against the blackness of the woods. A tethered pony now and then timidly approached, to swiftly scamper off again in fright at some sudden noise or motion. In the far distance the jagged outline of the sombre, passionless mountains came and went, with the fitful rise and fall of the lurid flames. And above us was spread a starlit sky, with a faintly shimmering moon to mitigate its seeming coldness. Really the sight of all this was like a poem, unwritten but yet felt.

Presently some mollified German thawed out in song. His example proved contagious. Soon he was joined by a full-voiced chorus, and the night-air rang with sweet melody. They sang long and well, those foreigners in a strange land. The enchanting strains of the old German *Volksleid*, alternated with the Tyrolese *Jodler*, or the more modern students' song. At times a plaintive, melancholy music, and again bright, joyous, laughing notes resounded through hill and valley with faint and fading reverberations. Never until then was the delicious cadence of such tones heard amid those surroundings.

But at length they too must cease. We sought the inviting warmth of our blankets. Presently no sound was heard save the gentle sighing of the breeze in the tree-tops. The pines still rocked and swayed, agitated by fitful gusts of moaning wind. Now and then the dying embers of the camp-fire were fanned back to momentary life. A sudden flame leaped up spasmodically, to perish quickly in the darkness. Above, the stars still glittered, cold, keen, impassive. Shrouded in gloom the camp lay sleeping.

At early dawn there was a harsh awakening to rude toilet and shivering breakfast. The actual experiences of the night before blended imperceptibly with the vivid dreams that had followed. A shadowy memory of pleasant by-gones was alone recalled by the heap of ashes that lay before us. The journey proceeded, and many strange, weird sights were seen. But it will not be possible to do justice to all we witnessed. Enough has been said to show that the Yellowstone Park deserves a visit, and will amply repay the tourist's outlay of time and money. The imperfections and discomforts inseparable from new regions will soon be measurably relieved. In time it must become a popular resort for foreign as well as native travelers. And now these random notes have finally ended, and the reader may feel relieved. Very truly yours,

EDMUND C. WENDT, M.D.

136 WEST THIRTY-FOURTH STREET, NEW YORK,

Army and Navy News.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from November 24 to December 1, 1883.

WOLVERTON, WILLIAM D., Major and Surgeon. Assigned to duty as Post Surgeon at Washington Barracks, D. C. S. O. 222, par. 7, Department of the East, November 27, 1883.

BROWN, PAUL R., Captain and Assistant-Surgeon. Assigned to duty in the Department of Arizona. S. O. 273, par. 4, A. G. O., November 28, 1883.

MERRILL, JAMES C., Captain and Assistant-Surgeon. Relieved from duty in the Department of the East, and assigned to duty at Columbus Barracks, Ohio. S. O. 270, par. 4, A. G. O., November 24, 1883.

BREWSTER, WILLIAM B., First Lieutenant and Assistant-Surgeon. Extension of leave of absence granted September 15, 1883, further extended two months. S. O. 271, par. 4, A. G. O., November 26, 1883.

MADDOX, THOMAS J. C., First Lieutenant and Assistant-Surgeon. Granted leave of absence for two months. S. O. 136, Department of the Missouri, November 24, 1883.

Official List of Changes in the Medical Corps of the Navy, for the week ending December 1, 1883.

KINDLEBERGER, D., Medical Inspector. To be relieved from duty on the Retiring Board, on December 9, 1883.

CHILD-BEARING LATE IN LIFE.—Dr. John Meredith, reports (*British Med. Jour.*) the case of a woman who gave birth to a child when forty-eight years of age.

New Instruments.

A NEW GALVANO-CAUTERY ÉCRASEUR.

By WILLIAM C. JARVIS, M.D.,

NEW YORK.

THE possibility of utilizing the mechanism of my cold-wire snare-écraseur¹ for operating with the incandescent electric loop, has occupied my attention

for many months. The experiments undertaken to accomplish this object have recently resulted in the construction of an instrument differing but little in shape and mechanism from the original écraseur. An examination of the accompanying illustration will facilitate a clear comprehension of the alterations. A tube has been attached to the main canula, *m c*, of the cold-wire écraseur. This additional canula only extends to the cross bar, *c d*, the main tube alone being continuous with the handle. The tubes are properly insulated at *i*. Each tube is provided with binding screws, *d*, the binding met on the small tube also serving to jam and retain one extremity of the wire. The wire also passes through the main tube, *m c*, and is wound around the retention pin, *r*, on the slide tube, *s t*. Inasmuch as the end of the wire in the small tube remains fixed, it will be observed that the size of the loop can only be changed by sliding the tube, *s t*, to which the movable extremity of the wire is attached. The relative position of the binding screws, *d*, to the cross-bar, *c d*, is intended to prevent any interference of the connecting battery wires, *c c*, with the manipulation of the instrument. An objectionable feature of double canulæ, that of permitting the growth to become constricted against its orifices, with consequent laceration of the last shred of tissue instead of its complete division by the wire loop, may be remedied by means of a peculiarly shaped slot cut into the orifice and inner side of each tube. By connecting both canulæ properly insulated with the orifice of the handle, the loop can be tightened as in the cold-wire écraseur.

With the assistance of my friend Dr. M. J. Roberts, I subjected the instrument to a careful test, which proved perfectly satisfactory. Masses of meat, equal in size to the largest growths, were divided with ease and completeness.

I consider the instrument particularly useful for removing the peculiar form of enlarged tonsil described by me in an article on "Tonsillotomy without Hemorrhage." Rapid excision of these tonsillar growths is invariably followed by profuse hemorrhage. The protracted strain caused by the cold wire, when used to evert this issue, drawing open the soft peri-tonsillar structures, sometimes constitutes an objection to be overcome by the employment of an incandescent electric loop. Dr. Henry Schweig informs me that, in his opinion, the heated wire will more certainly sink into the substance of supra-pharyngeal adenomata, and their complete removal will be greatly facilitated by the procedure. The instrument was constructed by Mr. W. F. Ford, with Caswell, Hazard & Co., whose well-

¹ New York Medical Record, April 30, 1881, etc.

known courtesy and skill I am always anxious to recognize.

For obvious reasons the soft galvano-caustic loop, generally speaking, must always prove inferior in usefulness to the elastic ring of tempered steel wire.¹

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending December 4, 1883:

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
<i>Cases.</i>								
November 27, 1883.....	0	33	64	2	36	37	0	0
December 4, 1883.....	0	32	44	1	51	39	1	0
<i>Deaths.</i>								
November 27, 1883.....	0	12	7	2	4	16	0	0
December 4, 1883.....	0	13	9	1	6	22	0	0

THE TOXIC EFFECTS OF NITRITE OF SODIUM.—It appears from several letters published by Drs. Murrell, Ringer, and Law that nitrite of sodium is dangerous in doses of twenty grains, as at first recommended. It should not be given in doses greater than two grains at first, increased to five grains if necessary.

A BAKED BEAN CAUSES DEATH.—Baked beans will hereafter be regarded with suspicion. This succulent and nutritive edible, for ages so popular in New England, has caused the death of a man at Lynn named Wallace Cobb. He died recently, and it was supposed that death was caused by an accident, but a post-mortem examination reveals the cause to be a hard-baked bean, which lodged in the appendix vermiformis, situated in the right iliac fossa, on the lower right-hand corner of the abdomen. Inflammation followed and finally caused death.

PEPTONIZED MILK IN ACUTE DYSPEPSIA.—Five grains of extractum pancreatis and twenty grains of bicarbonate of soda are dissolved in four ounces of tepid water. This is added to one pint of fresh milk warmed to the temperature of the body, and the mixture is allowed to digest for about one hour at a temperature of 100° F. The milk, when ready, should have a slightly bitter taste, or rather after-taste. It is now raised to the boiling point, strained, and placed on ice ready for use.

MERCURIAL SOAP.—Vomacka gives the following directions for the preparation of a substitute for blue ointment, which also keeps better: One part of soft and perfectly neutral potash soap is mixed with a little glycerine in a glass mortar, and one part of mercury is gradually added with constant trituration. When no globules of mercury are any longer visible, add two parts more of potash soap to make four parts. It may be scented with lavender or other essential oil.

THE STUDY OF BIOLOGY.—At the recent meeting of the Biological Section of the British Association, Professor Lankester advocated increased provision for the advancement of the science of biology. In this respect England was far below France and Germany, and even Holland, Belgium, Italy, and Russia. There were not wanting people who were anxious to restrain rather than aid the spread of scientific knowledge. But no one could trace the limits of science nor the possibilities of

happiness, both of mind and body, which it might in the future bring to mankind. As day by day the old-fashioned stimulus to the higher life loses the dread control which it once exercised over the thoughts of men, the pursuit of wealth, and the indulgence in fruitless gratifications of sense, become to an increasing number the chief concerns of their mental life. Such occupations fail to satisfy the deep desires of humanity, they become wearisome and meaningless, so that we hear men questioning whether life be worth living. When the dreams and aspirations of the youthful world have lost their old significance and their strong power to raise men's lives, it will be well for the community which has organized in time a following of, and a reverence for, an ideal good which may serve to lift the national mind above the level of sensuality and to insure a belief in the hopefulness and worth of life. The faith in science can fill this place; the progress of science is an ideal good—sufficient to exert this great influence.

MEMORY.—A man's memory is like his stomach. To do its best work it must have good treatment. It must neither be neglected nor overloaded. It can easily be so abused by neglect, or by irregular and unsystematic employment, as to become chiefly a cause of annoyance and discomfort; or, again, it can be so overworked and heavily taxed that it becomes practically the chief organ or agent of the entire system, every other portion dwindling in its comparison. The latter course is the great danger of those who value the help of a tenacious memory. Both memory and stomach are valuable, not in proportion to the burdens they can carry, but in proportion to their training for their part in the work of the system as a whole; and either of them is made effective as much by what is kept from it, as by what is packed into it.

DR. BROWN-SÉQUARD ON ANALGESIA BY A PROPOSED NEW METHOD.—Dr. Brown-Séquard has written the following very interesting letter to the *Lancet*: "Sir—My pupils, not I, have proposed to employ on our species the method I have discovered of producing analgesia in monkeys, dogs, and other animals. I am not prepared to make such a proposal; not that there is any danger in the method, nor that the degree of analgesia is insufficient, but because I have not yet succeeded in devising for clinical use an easy means of applying carbonic acid or chloroform vapor to the mucous membrane of the larynx, without allowing these substances to go into the lungs. This last point is of absolute necessity, as when these substances enter the blood they can no longer produce, by irritation of the mucous lining of the larynx, their wonderful effects. My experiments, some already published, others quite new, show that an irritation of the laryngeal mucous membrane (and also, but in a much slighter degree, of the lining of the upper part of the trachea) can, through the superior laryngeal nerves, or even through one of them only (but then the analgesic effect is chiefly unilateral), act on the nervous centres in such a way as to produce a more or less complete inhibition of either the power of perceiving impressions able to give rise to pain, or of the power of transmitting those impressions. Every kind of irritation (mechanical, thermic, chemical, or galvanic) of the terminal ramifications of the superior laryngeal nerves can produce that effect; but none in the same degree and with so great a persistence (in monkeys sometimes the analgesia lasts more than twenty-four hours) as the excitation due to carbonic acid or chloroform vapor, the first especially. The power of the parts I have named in producing an inhibition of the kind of sensibility relating to pain, without disturbing any other power or function of the nervous centres, is so great that sometimes a partial section of the larynx or trachea produces a temporary and almost universal, but incomplete analgesia."

THERAPEUTICS OF THE NAILS.—*Incurtatio Unguium.*—When the nail threatens to grow into the skin, or has already injured it, the first indication is to put on a sock

¹ New York Medical Record, May 27, 1882.

of moderate size and to remain quiet. Afterward the nail is to be scraped on the affected side till it is sufficiently thin; then it is to be seized with a delicate forceps, raising it in a sense inversely to its natural curvature. This having been done, a small lamina of lead of a few millimetres thickness is to be inserted beneath the nail, and after folding it over the toe it is to be fastened there with a strip of plaster. In this manner the granulations being no longer in contact with the margin of the nail, the pain ceases and the sore heals more or less rapidly; during the whole of which time the apparatus should be frequently inspected, so that the lamina of lead may not become displaced. Besides this, it is necessary to scrape the nail every two or three days so as to keep it thin and flexible, until the skin returns to its natural state and can resist the pressure of the nail, and then the lead is removed. Hebra treats ingrowing nail in the following manner: Cut some flakes of lint of the length of the lateral groove of the nail or a little longer. The lint is to be placed on the nail parallel to its groove; then with a flat probe introduce the lint, thread by thread, between the flesh and nail. Thus the parts are separated with the little cushion of lint lying between. The sulcus is then to be filled with pledgets of lint, and finally, long narrow strips of adhesive plaster are to be applied, always from above the inflamed sulcus downward, in such a manner that the latter is still further removed from the margin of the nail. With such a dressing applied with sufficient care, there is no pain whatever; and the patient can in a short time put on his ordinary stocking and walk without trouble. After twenty-four hours the strips of adhesive plaster are to be removed, being previously softened in a bath of tepid water. This dressing is to be repeated daily, and in from two to four weeks it will be found that the toe is entirely well. In those cases in which it is found that the nail is not abnormally implanted, and that it is the soft tissue only that grows in a vicious manner, I believe it will be well to remove the ulcerated tissues. This little operation, which may be performed without anæsthesia, deserves to be described. A double-edged bistoury held as a pen, is to be passed through the diseased tissues, taking care to graze the lateral margin of the nail where the disease exists. The tissues are then to be removed in such a manner as to expose the side of the nail which lies buried in the pulp. The wound should be washed with a solution of carbolic acid, and some lint placed on it like a cushion, which is firmly secured by a bandage, with some compression.—*Four. of Cutaneous and Venereal Diseases.*

TWO POUNDS OF TAPEWORMS.—M. Paul Agniel reports, in the *Semaine Médicale*, the case of a man, twenty-four years of age, who had never been ill, and whose appetite had always been good, who at intervals of a week had noticed the expulsion of segments of tapeworm. After preparation, an infusion of eighty grammes of pomegranate-rind was administered, followed by castor-oil. This brought away an enormous mass of tapeworm, which was found upon examination to consist of eleven worms, with their heads as shown by the hooplets. The mass weighed one kilogram, and the combined length of the different worms amounted to 34.50 mètres.

MEDICAL NOTIONS AMONG THE CHINESE.—Dr. C. H. Daniells, of Swatow, China, sends us the following interesting item: "Medical literature among the Chinese is abundant, 'of making many books there is no end,' but the correctness of ideas relating to medicine may be judged by reference to any of them. A book entitled 'Poems Relating to the Nature of Medicine,' affords a good degree of interest, although it contains no poetry—the title is given in order to please the Chinese ear. It treats of anatomy, physiology, and therapeutics, the thoroughness of which may be judged by the fact that it contains but one hundred and twenty pages. It fully elaborates the Chinese idea of the male and female principle in nature,

claiming for the heaven's male principle heat and warmth, for its female principle cold, while the earth's male principle is the agreeable and insipid, its female principle is the bitter, the sour, and the salt. Extending this idea to anatomy it makes every part of the human system to belong either to the male or female principle. It also presents the underlying principle of all Chinese medical practice, the classification of all diseases and remedies as hot and cold, with the theory for treatment. 'Hot remedies for cold diseases and *vice versa*.' Its anatomy divides the cavity of the human subject into three *apartments*, the upper contains the heart and lungs, the middle the liver and spleen, the lower the kidneys and the generative organs. It describes three pulses at each wrist, the lower pulse of both being the index to the upper apartment of the cavity, the middle to the middle apartment, and the upper pulse to the lower apartment. Thus the lower pulse of the right hand indicates the condition of the heart, that of the left hand the condition of the lungs, the middle pulse of the right hand indicates the condition of the liver, that of the left the spleen, etc. The human body is composed of gold, wood, fire, earth, and water. During the spring the wood predominates, and the liver being strong at that time, the pulse of the liver becomes the strong pulse of the body; during the summer the fire predominates and the heart pulse is the strong pulse; during the fall the gold predominates and the lung pulse is the strong pulse, while during the winter the water predominates and the kidney pulse is the strong one. The left hand belongs to the male principle, hence a man's left pulse is stronger than his right; the right hand belongs to the female principle, hence a woman's stronger pulse is in the right hand. The therapeutics of the book show considerable system in arrangement, the animal, vegetable, and mineral kingdoms being taken in order. A few extracts will give the estimate of their correctness. 'The bones of the tiger are of a mild nature, have an acrid taste, and are not poisonous. They drive poisons from the system, cure colds, numbness, and all discharging ulcers.' 'The flesh of a black rooster strengthens the bowels, the tendons control deafness, the intestines cure incontinence of urine, and the blood of the comb increases the milk of nursing women.' 'Peppermint relieves all forms of congestion and astringents cure diarrhoea.' The Chinese make use of herbs as domestic remedies. The people prize their own system of medicine, which ought to be popular—at least with their undertakers."

PROLONGING THE EXISTENCE OF THE POCKET THERMOMETER.—Dr. C. H. Eames, of East Saginaw, Mich., says: "A number of expedients have been proposed for prolonging the life of the pocket thermometer. May I add one? Have a pocket made to fit the thermometer."

DISLOCATION OF THE ANKLE FORWARD AND OUTWARD.—Dr. H. S. Thorne, of Farmingdale, L. I., sends the history illustrating the above rare condition: "On July 20, 1883, the Rev. Mr. Y—, aged sixty, height 6 feet 2 inches, weight 200 pounds, while in the loft of his stable attempted to descend on a stationary step-ladder to the floor below. He lost his footing and fell a distance of eight feet, striking first the lower step of the ladder with his left heel, dislocating the ankle *forward*, and then, after the rebound, struck the floor with the outer side of the foot, throwing the ankle violently outward. When first seen the foot was in a position nearly at right angles to its true one. The internal malleolus was at the inner border of the plantar surface of the foot and strongly pressing against the scaphoid bone, the outer malleolus formed a prominent bony tumor at the outer side of the heel, and the articular surface of the astragalus was two inches in front of the outer malleolus and pushing the skin of that part of the dorsum of the foot on which it impinged out to such an extent as to be on the point of penetrating it, having forced its way through the ligaments, fascia, and tendons until

nothing but the skin itself stood in the way of the injury being a compound luxation. There was no fracture of either malleolus. Two hours after the injury the patient was etherized. Owing to the peculiar deformity it was not deemed advisable to follow the usual method of reduction, *i.e.*, to flex the leg and then extend. The leg was kept extended and held firmly by an assistant while the heel was grasped by the right, and the dorsum of the foot by the left hand, and forcible extension and manipulation were made. The foot was twisted in such a manner as would compel the astragalus to retrace the path it had made in getting into its abnormal position through the soft parts. In this manner the reduction was perfectly effected without very great difficulty. A roller was firmly applied and side splints put on. Hot applications were freely used and hot-water baths every day. The foot was rubbed and kneaded to prevent solidification of effused material, and the limb was elevated. On the twenty-second day the patient was able to use crutches; on the thirty-sixth he walked with a cane, and now, ten weeks after the injury, he goes without the cane, does not limp, and there is no swelling or stiffness of the joint."

THE THERAPEUTIC VALUE OF BICYCLING.—Dr. Geo. S. Hull says in the *Medical Times and Gazette*: "Concerning the therapeutics of the bicycle, it is not making too broad a statement to say that it can be recommended in nearly all cases where horseback riding is indicated, the exceptions being ladies and very old or crippled men, and for most of these the tricycle is still preferable to the horse, and certainly infinitely safer. In horseback-riding the inexperienced rider gets the most exercise (jolting, which is not always beneficial), while the skilful horseman merely gets the pure air, and very little above the usual amount of that, as his circulation and respiration are not much increased by the easy, quiet motion his *skill* as a horseman gives him. In fact, after learning to ride horseback, it often becomes tiresome, the exhilarating effect passes off, and the good results consequently diminish. In bicycling, however, the whole body is in motion, and every rider gets a like amount of exercise. The circulation is quickened to any extent; the blood-vessels of the limbs are not compressed to the extent they are in horseback-riding; there is but little or no jarring; the muscles of the trunk and upper extremities (which, as a rule, are so imperfectly developed in physicians), are brought more into play, and the mind kept actively engaged in the sport—for sport it becomes, even when flying along to a 'terrible accident,' or to a death-bed scene."

ON BANDAGING THE INFANT.—In his retiring address Captain Douglas Galton, President of the British Sanitary Institute, delivered a philippic against the baby-bandage. He condemned what he described as "those mischievous two yards of calico," which, wound round the middle of so many infants on their introduction into the world, as a sort of baptism to the numerous evils of fashion in dress to which they were admitted, constricted and hindered the expansion of that very region of the body where heart and lungs, stomach and liver, organs of no mean importance, were struggling for room to grow and do their work, and where natural mechanical conditions threw some difficulty in the way of full development. The expansion of the lower part of the chest, which was so pronounced a feature in the well-formed human figure, was attained chiefly in higher animals, and like most of such higher prerogatives, was the result of more than ordinary effort, and was, proportionately, liable to suffer from interference. The chief effort to accomplish it was made soon after birth, when breathing, and food-taking, and the various changes incidental upon them began; and at this very juncture the opportunity was taken by meddling hands to hinder the expansion of the region where these new processes, upon which the well-being of the whole fabric depended, had to be initiated

and carried out. A more pernicious device could scarcely be conceived than this relic of antiquated nursedom; and it was impossible to estimate the number of deformed or pigeon chests, of hampered stomachs, livers, lungs, and hearts, with their varied attendant life-enduring infirmities and curtailment of life, that must result from the use of these "swathers," as they were called, for which there was not the slightest necessity. The oft-condemned tight waistbanding and lacing of after years, which affected only the small fashionable section of one-half of the community, was not, even in those who were subjected to it, so mischievous as this concealed semi-strangling process which was diligently carried out in the case of a large proportion of infants of all classes. Of the three demands of the infantile period—liberty of movement, fresh air, and good food—it seemed strange that the first two should be limited by smothering bed-clothes, swathers, long petticoats, and other devices, together with imperfect ventilation of rooms, while the last was liable to be supplied sometimes in sufficient quantity and bad quality, but often, whether good or bad, in superabundance.

THE PREVENTION OF HORSE ACCIDENTS.—Mr. C. C. Baird, of the Dick Veterinary College, Edinburgh, has invented an india-rubber frog-pad for fitting into the heels of the shoes of horses, with the view of preventing the animals from slipping and falling on the causeway. The invention is exceedingly simple, and will be of great value to medical men and others who drive horses, especially on asphalt and in frosty weather. The pad can be removed in the evening and replaced in the morning. A set of pads, it may be added, is expected to wear out two sets of shoes. The trial of the invention, we believe, has fully borne out the statements of the inventor as to the merits of the apparatus.—*Medical Press*.

A leather pad, considered superior to the rubber article, is coming into use in Louisville.—*Louisville Medical News*.

A LINIMENT FOR RHEUMATISM.—The *Therapeutic Review* says: "Methyl salicylate (oil of wintergreen) mixed with an equal quantity of olive-oil or linimentum saponis, applied externally to inflamed joints affected by acute rheumatism, affords instant relief, and, having a pleasant odor, its use is very agreeable."

THE REAL MISSING LINK.—Dr. Struthers, at a meeting of the British Association, said he had once in Aberdeen had to examine the case of a body reported to have a tail, but he found that it was simply a case of misdirection of the natural bones, and so the tail case broke down. The anthropologists were often jokingly asked when they were going to find a man with a tail. It should be remembered that even the higher apes had no tail, and therefore the question of tail or no tail was of no importance. To discuss the missing link was to tread on dangerous ground. Hair would never settle the question. The great point was the brain. The missing link was not a link, but a chain. The brain was one link, and the other was erect posture. If we could conceive a monkey having somehow got one day an abnormally superior brain, it would not remain up a tree. Then his limbs would commence to adapt themselves to their new conditions. Given the larger brain and the larger intelligence, the other development would follow in the course of time. The missing link, in one of the most painful senses, could be seen any day in the idiot ward of an asylum.

COCA-PLUG.—A combination of coca and tobacco is being quite extensively advertised in the St. Louis papers. Certificates from six prominent St. Louis physicians to the effect that tobacco and coca would be less injurious to the system than tobacco alone form a part of the advertisement.—*Medical World*.

CEREBRO-SPINAL FEVER.

(SPOTTED FEVER. CEREBRO-SPINAL MENINGITIS.)

By J. LEWIS SMITH, M.D.,

CLINICAL PROFESSOR OF DISEASES OF CHILDREN, BELLEVUE HOSPITAL MEDICAL COLLEGE.

(Continued from p. 620.)

Nature.—The theory that cerebro-spinal fever is a local disease, occurring epidemically, was commonly held in the first part of this century, a theory which is now discarded. Job Wilson, in 1815, considered it a form of influenza, and he could see no utility in drawing a distinction between spotted fever and influenza. We, at the present time, can see no resemblance between the two, except that both occur as epidemics. The theory that cerebro-spinal fever is a peculiar local disease occurring in epidemics is more plausible than that it is a form of influenza. Even Niemeyer says that it presents no symptoms except such as are referable to the local affection. But the evidence is strong that cerebro-spinal fever is a constitutional malady, with the meningitis as a local manifestation, just like measles with its bronchitis, or scarlet fever with its pharyngitis. The abrupt and severe commencement, unlike that of those forms of meningitis, which are known to be strictly local, and the early blood change, as shown in certain cases by the appearance of the skin, and extravasations under it, indicate a general disease. Constitutional diseases having prominent local symptoms and lesions are apt to be regarded at first as local. It is only as time goes on, and they are more thoroughly studied and understood, and clinical observations multiply, that their constitutional nature is recognized, as for example at this late day the profession are beginning to recognize the constitutional nature of certain cases of croupous pneumonitis.

The theory that cerebro-spinal fever is a form of typhus once had advocates, but it is now so generally discarded, as untenable and absurd, that it would be a waste of time to consider the facts which differentiate the two maladies. Cerebro-spinal fever should, therefore, be considered as distinct from all other diseases, a malady *sui generis*, and in nosological writings it should be classified with those constitutional maladies which have specific causes.

Although this disease ordinarily occurs in an epidemic form, in localities widely separated from each other, and after continuing a few weeks or months, totally disappears, perhaps never to return, or not till after the lapse of years, nevertheless in certain localities it becomes established, so that it is proper to describe it as an endemic, a fact to which we have already alluded as regards New York City. I do not know that it is endemic in any village or rural locality in this country, but it appears to be permanently established in certain of the large cities. The large cities, with their promiscuous population, foreigners and natives, their crowded tenement-houses, and many sources of insalubrity, furnish in an eminent degree the conditions which are favorable for the development and perpetuation of the specific principle. Those diseases which in the present state of our knowledge we have reason to believe are caused by micro-organisms, we would expect to prevail most where domiciles are crowded and filthy, and systems are ener-

vated by impure air, poor diet, hardships and privation. Hence in New York City, in the quarters of the poor, there is a constant succession of the infectious diseases of childhood. Often two or more of them occur simultaneously, and it is difficult to eradicate them or limit their extension when once they have obtained a foothold. The fact that a large city, with its tenement-house population, affords in an eminent degree the conditions in which the infectious diseases are developed and propagated, when once their specific principles have been introduced, is one of the chief causes of the large percentage of deaths among the city children. In New York what has been gained in saving life by the suppression of small-pox has been more than counterbalanced by the mortality produced by diphtheria and cerebro-spinal fever, both now to all appearance permanently established in our midst. The following table gives the number of deaths annually from cerebro-spinal fever in this city since the close of 1871:

	Number of deaths.		Number of deaths.
1872.....	782	1878.....	97
1873.....	290	1879.....	108
1874.....	158	1880.....	170
1875.....	146	1881.....	461
1876.....	127	1882.....	238
1877.....	116		

It is seen that the greatest mortality was in the first year after the introduction of the disease into the city, after which the number of deaths gradually diminished, year by year, till 1878, when the lowest mortality was reached. Since 1878 the mortality gradually increased till 1881, in which year the number of deaths was double that of any other year except 1872, it being half that of 1872. The weather and the season appear to exert little influence on the prevalence of this disease now that it is established in the city. From the commencement of 1882 till the end of May of the current year I find that it caused deaths in every week except one, and about the same number in each of the seventeen months embraced in this period.

The mortuary reports of Philadelphia likewise show that cerebro-spinal fever has remained in that city since its introduction in 1863, a period of twenty years, the annual deaths produced by it varying between 36, the minimum, in 1869 and 1870, and 384, the maximum, in 1864. In Providence, also, as appears from Dr. Snow's reports, cerebro-spinal fever has caused annually more or fewer deaths since 1871. Therefore, we repeat, this fact may be added to the sum of our knowledge of this disease, that once gaining a lodgment, where the conditions are favorable for it, as in a large city, it may become established and remain there an indefinite time.

Anatomical characters.—I have notes of the post-mortem appearances in 76 cases, published chiefly in British and American journals; 29 died within the first three days, 28 between the third and twenty-first days, and the duration of the remaining 11 was unknown. These records furnish the data for the following remarks:

The blood undergoes changes which are due in part to the inflammatory and in part to the constitutional and ashenic nature of the disease. The proportion of fibrin is increased in cases that are not speedily fatal, as it ordinarily is in idiopathic inflammations. Analyses of the blood by Ames, Tourdes, and Mallot show a variable proportion of fibrin from 3.40 to more than six parts in

1,000. In sthenic cases accompanied by a pretty general meningitis, cerebral and spinal, there is, after the fever has continued some days, the maximum amount of fibrin, while in the asthenic and suddenly fatal cases, with inflammation slight, or in its commencement, the fibrin is but little increased. The most common abnormal appearance of the blood observed at autopsies is a dark color with unusual fluidity and the presence of dark soft clots. Exceptionally bubbles of gas have been observed in the large vessels, and the cavities of the heart. An unusually dark color of the blood, small and soft dark clots, and the presence of gas-bubbles, when only a few hours have elapsed after death, indicate a malignant form of the disease, in which the blood is early and profoundly altered. In certain cases this fluid is not so changed as to attract attention from its appearance. The points or patches of extravasated blood which are observed in and under the skin during life in some patients usually remain in the cadaver. When an incision is made through them the blood is seen to have been extravasated not only in the layers of the skin, but also in the subcutaneous connective tissue. Extravasations of small extent are also sometimes observed upon and in the thoracic and abdominal organs.

In those who die after a sickness of a few hours or days, namely, in the stage of acute inflammatory congestion, the cranial sinuses are found engorged with blood, and containing soft dark clots. The meninges enveloping the brain are also intensely hyperæmic, in their entire extent in most cadavers; but in some cases the hyperæmia is limited to a portion of the meninges, while other portions appear nearly normal. In those cases which end fatally within a few hours, this hyperæmia is ordinarily the only lesion of the meninges; but if the case be more protracted, serum and fibrin are soon exuded from the vessels into the meshes of the pia mater, and underneath this membrane, over the surface of the brain. Pus-cells also occur mixed with the fibrin, sometimes so few as to be discovered only with the microscope, but in other cases in such quantity as to be much in excess of the fibrin, and be readily detected by the naked eye. Pus, which in these cases probably consists of white blood-corpuscles which have escaped with the fibrin from the meningeal vessels, sometimes appears early in the attack. Thus in the *Dublin Quarterly Journal*, 1866, Dr. Gordon relates the history of a case in which death occurred after a sickness of five hours, and a purulent greenish exudation had already occurred in places under the meninges. The exudation of fibrin also begins early. In a case of thirty hours' duration, published by Dr. William Frothingham in the *American Medical Times*, April 30, 1864, and in another of one day's duration, published by Dr. Haverty, in the *Dublin Quarterly Journal* for 1867, exudation of fibrin had already occurred in and under the pia mater. The arachnoid soon loses its transparency and polish, and presents a cloudy appearance over a greater or less extent of its surface. This cloudiness is usually greatest along the course of the vessels in the sulci and depressions, and where the fibrinous exudation is greatest, but it occurs also where no such exudation is apparent to the naked eye. Dr. Gordon describes a case of only eight hours' duration, in which the arachnoid was already opaque at the vertex, but of normal appearance at the base of the brain (*Dublin Quarterly Journal*, 1866), though the vessels of the pia mater were everywhere greatly congested.

The exudation—serous, fibrinous, and purulent—occurs as in other forms of meningitis, within the meshes of the pia mater, and underneath this membrane over the surface of the brain. The fibrin is raised from the surface of the brain with the meninges. It is most abundant in the inter-gyral spaces, around the course of the vessels, over and around the optic commissure, the pons Varolii the cerebellum, medulla oblongata, and along the Sylvian fissures. It is most abundant in the depressions, where

it sometimes has the thickness of $\frac{1}{10}$ to $\frac{1}{4}$ of an inch, but it often extends over the convolutions so as to conceal them from view.

Most other forms of meningitis have a local cause, and are therefore limited to a small extent of the meninges, as, for example, meningitis from tubercles or caries of the petrous portion of the temporal bone, in both of which it is commonly limited to the base of the brain; or from accidents, when the meningitis commonly occurs upon the side or summit of the brain. The meningitis of cerebro-spinal fever, on the other hand, having a general or constitutional cause, occurs with nearly equal frequency upon all parts of the meningeal surface, except that it is perhaps most severe in the depressions, where the vascular supply is greatest. In cases of great severity the inflammatory exudation, fibrinous or purulent, or both, may cover nearly or quite the entire surface of the brain. Thus in the case of a negro, thirty-five years old, only four days sick, whose body was examined in Bellevue Hospital on May 30, 1872, the record states that there was a purulent exudation over the entire surface of the cerebrum and cerebellum. The quantity of serous exudation varies according to the duration of the disease and amount of congestion. In some the quantity is so small as scarcely to attract attention, but in other instances, especially when the disease is protracted, it is large. In a case reported by Dr. Moorman, in the *American Journal of the Medical Sciences*, for October, 1866, it is stated that about three pints of turbid serum escaped from the cranial cavity in attempting to remove the brain; but as there was no measurement the statement may be somewhat exaggerated.

In those who die at an early stage of the attack, the vessels of the brain, like those of the meninges, are hyperæmic, so that numerous "puncta vasculosa" appear upon its incised surface. At a later period this hyperæmia, like that of the meninges, may disappear. If there be much effusion of serum within the ventricles, and over the surface of the brain, the convolutions are apt to be flattened, and the pressure may be so great that the amount of blood circulating in the brain is reduced below the normal quantity. Thus in the case of a child of three years, who lived sixteen days, and was examined after death by Burdon-Sanderson, the ventricles contained a large amount of turbid serum, and the brain-substance was everywhere pale and anæmic.

Cerebral *ramollissement* occurs in certain cases. At one of the examinations in Charity Hospital, the patient having been only three days sick, the brain was found much softened. The dissection was made seven hours after death, so that the softening could not have been the result of decomposition. At one of the post-mortem examinations in Bellevue Hospital, softening of the fornix, corpus callosum, and septum lucidum was observed, and in another, softening in the neighborhood of the subarachnoid space. In a case related by Dr. Moorman in the *American Journal of the Medical Sciences*, for October, 1866, it is stated that portions of the brain, medulla oblongata, and pons Varolii were softened. In a case observed by Dr. Upham softening of the superior portion of the left cerebral hemisphere had occurred. Occasionally the whole brain is somewhat softened. Burdon-Sanderson, Russell, and Githens each relate such a case. Moreover, the walls of the lateral ventricles are ordinarily more or less softened in fatal cases of cerebro-spinal fever, as they are in the usual forms of meningitis. In rare instances the brain is œdematous, as in a case published by Dr. Hutchinson in the *American Journal of the Medical Sciences*, for July, 1866. In this case the patient was only four days sick, and the whole brain was œdematous, serum escaping from its incised surface.

The ventricles contain liquid, in some patients transparent serum, in others serum turbid, and containing flocculi of fibrin, or fibrin with pus. The liquids in the different ventricles, since they inter-communicate, are the same. The choroid plexus is either injected or it is infil-

trated with fibrin and pus. With the abatement of the inflammation absorption commences. The serum, from its nature, is readily absorbed, and the pus and fibrin more slowly by fatty degeneration and liquefaction. Occasionally the serum remains, and chronic hydrocephalus results. An infant who contracted the disease at the age of five months, and appeared to be convalescent, had, two months subsequently, great prominence of the anterior fontanelle, and other symptoms which indicated the presence of a considerable amount of effusion within the cranium. In another case, one year afterward, examination showed the enlargement of the head and prominence of the fontanelle which characterize chronic hydrocephalus. A boy of ten years, treated in Roosevelt Hospital in 1878, died three months after the commencement of cerebro-spinal fever. The records of the autopsy state: "Body a skeleton; brain, dura mater and pia mater appear normal, except a little thickening of latter at base of brain; ventricles much enlarged and full of clear serum; surface of walls of ventricles appears normal, but is soft; spinal cord and membranes apparently normal; heart, lungs, stomach, and intestines normal; liver congested; kidneys pale." In this case, therefore, all the other lesions of the cerebro-spinal axis, except the serous effusion, had nearly disappeared. No post-mortem examinations, so far as I am aware, have yet revealed the state of the brain and its meninges in those who have had this malady at some former time and have fully recovered, whether there may not be some traces of it which are permanent, as opacity or adhesions.

The remarks made in reference to the cerebral apply, for the most part, also, to the spinal meninges. There is at first intense hyperæmia of the membranes, usually over the entire surface of the cord, soon followed by fibrinous, purulent, and serous exudation in the meshes of the pia mater, and underneath this membrane. The exudation is sometimes confined to a portion of the meninges, more frequently that covering the posterior than anterior aspect of the cord, and when it is general it is ordinarily thicker posteriorly than anteriorly. In severe cases nearly or quite the entire spinal pia mater may be infiltrated by inflammatory products. Thus in case of an infant that died of cerebro-spinal fever at the age of ten weeks, in the service of Dr. H. D. Chapin, in the out-door department at Bellevue, the entire spinal cord was covered by a fibrino-purulent exudation, except a space about six lines in extent upon the anterior surface.

At the meeting of the New York Pathological Society, March 23, 1881, Dr. G. L. Peabody presented the specimens from the body of a patient, aged nineteen years, who died on the tenth day of cerebro-spinal fever. The exudation extended over the base of the brain, both lobes of the cerebellum, and covered completely the cord to the cauda equina, being, as usual, thickest upon the posterior surface. In some patients the spinal meningitis is severe, while the cerebral is slight, so that the symptoms referable to the spinal axis predominate, such as pain in the back and limbs, and opisthotonos. The exudation may have the usual appearance of fibrin and pus, but it is sometimes greenish and sometimes blood-stained. Small extravasations of blood also occur as a result of the hyperæmia, and in one case related by Burdon-Sanderson it is stated there was a layer of blood one-eighth of an inch thick over the whole cord below the bronchial swelling. In post-mortem examinations the central canal of the cord has usually been overlooked. Ziemssen relates a case, and Gordon another, in which it was dilated and filled with purulent fluid. The anatomical changes which have been observed in the cord itself have been injection of its vessels in recent cases, and occasional softening of portions. Thus in a case which was examined in Bellevue Hospital, April 13, 1872, it is stated that there was softening of the cord in the upper part of the dorsal region. In most of the examinations the only abnormal appearance detected in the cord was hyperæmia, but in a consider-

able proportion of cases the records state that the substance of the cord appeared normal.

Professor Wm. H. Welch, curator to Bellevue Hospital, has recently communicated to me the following results of his examinations:

"I have records of eight autopsies which I have made upon cases of cerebro-spinal meningitis, and in six cases I have examined, microscopically, portions of the hardened brain and cord. Post-mortem rigidity is usually well marked and continues for a long time after death. Upon removal of the skull-cap, which is often hyperæmic, the dura mater appears tense, and usually more or less congested. The sinuses contain loose, dark-red coagula, and some fluid blood. In one case I found a recently formed grayish-red ante-mortem thrombus in the left lateral sinus. The subdural space is usually free from inflammatory exudation, but occasionally a slight fibrino-purulent exudation is found on the outer surface of the arachnoid membrane. The pia mater is generally hyperæmic, and frequently it contains small ecchymoses. An exudation is present in the subarachnoid spaces, over both the convexity and the base of the brain, most abundantly, as a rule, at the base. Over the convexity the exudation appears in the form of greenish-yellow streaks along the veins between the gyri. At the base the exudation accumulates in the subarachnoid cisterns, such as those of the Sylvian fissure, of the optic chiasm, of the intercrural space, of the under surface of the cerebellum, and along the basilar artery. The cranial nerve-trunks may be enveloped in a purulent exudate as they emerge from the brain. The fluid in the ventricles may or may not be increased in amount, but is usually turbid from admixture of pus-cells. The choroid plexuses are often swollen and opaque.

"The substance of the brain is usually hyperæmic, and frequently contains punctate ecchymoses, which may occur in groups. Small foci of softening may be formed before death, but extensive diffuse softening, particularly that around dilated ventricles (hydrocephalic softening) is probably cadaveric, and due to imbibition of serum, although it may form within a short time after death.

"The inflammatory exudation occupies likewise the subarachnoid space over the cord. The exudation may surround the posterior nerve-roots for a distance from the cord. Microscopic examination shows that the exudation is composed of serum, fibrin, pus cells, and red blood-corpuscles. Usually the exudation is distinctly purulent, being of a greenish-yellow color, but it may be predominantly serous in character. The pus-cells are accumulated around the small veins and capillaries. I have found the ependyma of the fourth ventricle richly infiltrated with pus-cells, which here as well as elsewhere are probably emigrated white blood-corpuscles. The connective tissue cells of the pia-arachnoid membrane are swollen and granular. The lymph spaces around the blood-vessels in the cerebral cortex are often filled with pus-cells. The communication between these peri-vascular spaces and the subarachnoid spaces renders easy the passage of wandering cells from the pia mater into the cortex. There may also be found an increased number of lymphoid cells in the peri-ganglionic spaces. In a similar manner the sheaths of the blood-vessels and the pial processes in the spinal cord may be invaded by pus cells.

"In one of my cases the symptoms of the disease are said to have existed for only twelve hours before death. Here there was an excess of serum in the cerebral and spinal subarachnoid spaces. This serum was moderately turbid. The microscope showed a more abundant exudation of pus-cells than there appeared to be from their gross appearances. The substance of the brain was pale and cedematous, nor was there marked congestion of the meninges."

No constant or uniform lesions occur in the organs of the trunk, and those observed are not distinctive of this disease. Hypostatic congestion of the lungs, bronchitis,

atelectasis, and broncho-pneumonia are common. Pleuritic, endocardial, and pericardial inflammations have occasionally been observed, but are rare. Effusion of serum, sometimes blood-stained, occasionally occurs in the pleural and other serous cavities. The auricles and ventricles of the heart, as already stated, contain more or less blood, with soft dark clots in the more malignant and rapidly fatal cases, but larger and firmer in those which have been more protracted. The spleen is enlarged in less than half the patients. The absence of uniformity as regards the state of the spleen, the fact that in many it undergoes no appreciable change, is important, since this organ is so generally enlarged and softened in the infectious diseases. The stomach, intestines, and liver are sometimes more or less congested, but in other cases their appearance is normal. The agminate and solitary glands of the intestines have ordinarily been overlooked, but in certain cases they have been found prominent. The kidneys in some exhibit the lesions of nephritis. In one of the eight autopsies made by Professor Welch acute diffuse nephritis had been present, as shown by the state of the kidneys. In the case of a child of nine years, treated by Dr. F. A. Burralk, in the Presbyterian Hospital, the urine was very albuminous and the kidneys presented a fatty appearance. Anatomical changes in these organs, however, are not common, unless in slight degree, so that in most patients their function is fully and properly performed.

(To be continued.)

THE PREVENTION AND TREATMENT OF PUERPERAL FEVER.¹

By T. GAILLARD THOMAS, M.D.,

NEW YORK.

DR. THOMAS said his motive for presenting the paper was involved in the fact that the plan of treatment of puerperal fever which he should advocate had not been anywhere fully elaborated, or in any single essay carefully systematized. Indeed the general principles of the plan of treatment had not been universally accepted as orthodox, and the question of intra-uterine antiseptic injections for the cure of puerperal septicæmia was one which would still come up for discussion. While the paper contained nothing which had not been elsewhere as fully and as clearly stated, and nothing which had not already received careful investigation at the hands of progressive obstetricians, the author hoped that on account of his large experience, the presentation of his estimate of the method might prove of some value. At the annual meeting of the American Gynecological Society, held four years ago, the subject of intra-uterine antiseptic injections for the cure of puerperal septicæmia was up for discussion, and with a single exception he stood alone in its advocacy. Furthermore, he was among the very first, if not the first in this country, who adopted this method, together with early cutaneous refrigeration in the treatment of this disease. Among all the advancements which have been made in obstetrical medicine he regarded none as more important or more signal than that relating to the prevention and cure of the febrile conditions incident to the puerperal state. Brief reference was then made to the views which have been entertained concerning its exact nature, such as a fever due to suppression of the lochia, inflammation of the uterus and peritoneum, specific puerperal fever, uterine wounds, arrest of the process of formation of milk, the doctrine of the multiplicity of puerperal affections grouped under one name, and the doctrine of puerperal blood-poisoning, etc.

Dr. Thomas then directed attention to the condition of the blood in the puerperal woman, first, being favorable to the development of thrombus, and, second, the

existence of a tendency to prove most prolific ground for sepsis and zymosis. Besides this, the nervous system is in a plus state of excitement and sensitiveness. With this general condition there existed several local conditions which result from parturition. Before enumerating these, he briefly alluded to the normal condition of the lymphatics, the blood-vessels, and the uterine tissue, and then described the appearances, as could be seen forty-eight hours after delivery. Outside all looks very well, the uterus is simply much larger than the non-pregnant womb, but the inner surface has an unhealthy, diphtheritic look, although free from exudation. There is a large raw, irregular placental site, and small clots can be seen which cover the mouths of the uterine sinuses. The odor from this surface is disagreeable. On examining the cervix uteri there may be found two or three small lacerations, and, in consequence of these, with absorption through them of irritating lochial discharge, the cervix is swollen and œdematous. Examining the vagina, it is found that in two or three places a superficial rupture of the mucous membrane of this canal has been produced. The vulva also presents several solutions of continuity, the fourchette has been torn through, and this rent has extended perhaps through a small portion of the perineum, and one or two small fissures have occurred in the mucous membrane covering the ostium vaginae.

Material taken from these surfaces at this stage of the puerperal state, and introduced by inoculation, will give rise to more or less irritation and lymphangitis, but it is not sufficiently poisonous to give rise to erysipelas or angioleucitis. And yet what are the results of parturition? Recovery is the universal rule unless some unusual occurrence manifests itself to prevent this consummation. Notwithstanding the existence of all these circumstances, which are best calculated to insure a bad result, only one or two of one hundred parturient women die when properly cared for, even in public hospitals.

But now and then all this is changed, and some poison gains access to the genital canal, and acts as rapidly and decidedly as a little yeast added to dough, and striking and alarming phenomena develop, spread, and progress steadily toward a fatal issue. At the morning visit the physician leaves the patient with a normal pulse and temperature, and in an apparently favorable condition. A few hours only may elapse when the patient has a scarcely perceptible chill, with some pelvic pain, the lochia ceases, the milk has disappeared, she suffers from severe headache, a look of indescribable anxiety is upon her face, she has a pulse of 120, and a temperature of perhaps 104° F. The poisonous element has reached the genital tract and the result is already manifesting itself. Suppose, now, that the physician remains inactive, or relies upon medicines given by the mouth which are supposed to exercise some control over this poison, the local conditions in the meantime which favor its admission remaining unchanged. The lymphatics are active, lymphangitis follows, cellulitis, peritonitis develops probably, and what was originally a septicæmia will emerge into one of those affections which have been grouped under the general name puerperal fever, and pass through all its attendant phenomena.

PATHOLOGY.

At this point the author of the paper proceeded to the consideration of the pathology of puerperal fever, and defined it as a puerperal septicæmia. It matters not whether it assumes a form of phlebitis, cellulitis, lymphangitis, or peritonitis, the essence of the disorder is absorption of poison into the blood of the parturient woman through some solution of continuity in the tissues of the genital tract. As had been well described by Lusk, puerperal fever is "an infectious disease, due, as a rule, to the septic inoculation of the wounds which result from the separation of the decidua and the passage of the child through the genital canal." In other words, he ac-

¹ Abstract of paper read before the New York Academy of Medicine, December 6, 1883.

cepted the definition given by Hervieure as long ago as 1870, who defined this disease to be "a multiplicity of affections produced by puerperal poison."

NOMENCLATURE.

Concerning nomenclature, of late an effort has been made by the Dublin school of midwifery to supplant the old term puerperal fever by the use of the word "metria." Dr. Thomas hoped the suggestion would not be adopted, as the word metria does not convey any more accurate idea of the pathology to the mind of the student than does the old term. Of the two terms metria is more objectionable than puerperal fever. On the other hand puerperal septicæmia conveys a definite and clear idea, which appears to be in accord with the truth as taught us by modern pathology, and it should be adopted despite the fact that it is far from being absolutely perfect.

Dr. Barnes had proposed to use the word in its comprehensive sense, employing it to mean that "the blood of the puerpera is poisoned," and Dr. Thomas was willing to admit this, although he believed in the existence of a specific poison which acted as surely as does a specific poison in the production of typhus or of small-pox. As to the exact nature of the poison we are not yet able to say; nor are we able to say what the exact nature of the poison is in most, if not all, the infectious diseases. German pathologists declare that the round micrococci especially are important factors in the etiology of this group of affections, but this point in bacterial pathology is too unsettled to permit of its introduction into such a paper as the present one. But even if we do not know what the nature of the poison is, we surely know that some such toxic agent exists, and it behooves us to inquire how it can be best destroyed, or how its life and activity can be best counteracted if it gains admission despite our care and watchfulness. There are only two methods by which it can reach the parturient tract. First, it may be carried into the vulva through the atmosphere; and second, it may be carried to any part of the genital tract by the fingers of the doctor or nurse, towels and cloths laid against the vulva, sponges, and instruments, and by bed and body clothing coming in immediate contact with the genital organs. Dr. Thomas then addressed his remarks to cases occurring chiefly in private practice, because even among the wealthy there is a laxity of system and a carelessness with regard to preventive measures which borders closely upon criminality. It is the duty of every practitioner to guard his patient against puerperal septicæmia by every means in his power.

PROPHYLACTIC MEASURES.

1. In all midwifery cases, whether in hospital or private practice, the floor and ceiling of the room in which the woman is to be confined should be thoroughly washed with a ten per cent. solution of carbolic acid, or a bichloride of mercury solution, one to one thousand. The bedstead and the mattress should be sponged with the same solution. All curtains and upholstery should be dispensed with.

2. The nurses and physician should take care that all their clothing is free from exposure to the effluvia of septic infection, such as typhus, erysipelas, septicæmia, scarlet fever, etc., and if there has been any exposure in this direction all the clothing should be changed and the body should be thoroughly sponged with a saturated solution of boracic acid.

3. As labor sets in the nurse should thoroughly wash her hands with soap and water, removing the dirt from under the nails, administer an antiseptic vaginal injection, repeat it every four hours during labor, and keep a napkin wrung out of the same antiseptic solution over the genitals until the birth of the child.

4. Both doctor and nurse should wash their hands

thoroughly with soap and water, and scrape the nails, and afterward soak their hands for several minutes in a solution of bichloride of mercury (1 to 1,000).

5. The third stage of labor should be efficiently produced, all portions of placenta should be removed, and ergot administered in moderate doses three times a day, to be kept up for at least one week, to secure complete expulsion of the clots and closure of the uterine vessels.

6. The doctor should take nothing for granted, but at the conclusion of labor should carefully examine the vulva of the patient. If there is any rupture of the perineum it should be closed at once by suture, and if slight lacerations are found they should be dried thoroughly with a cloth, and equal parts of a saturated solution of carbolic acid and persulphate of iron applied, and again the surface dried with a cloth and painted over with gutta-percha collodion.

7. Within six or eight hours after the termination of labor, syringe out the vagina with an antiseptic solution, and introduce a suppository of cocoa butter containing from three to five grains of iodoform.

8. The vaginal injections should be repeated every eight hours. But in all cases of difficult labor, and in those in which instruments have been employed, they should be administered twice as often, and kept up at least for ten days. The nurse must wash and disinfect her hands before every approach to the genital tract of the woman.

9. Employ a new gum elastic catheter which has been thoroughly immersed in an antiseptic fluid each time the bladder is evacuated, rather than trust the nurse to cleanse an old silver catheter.

10. The physician must inform himself by *personal observation* as to the competency of the nurse with regard to the use of the catheter, the administration of the vaginal injections, and the introduction of the suppositories.

It might be objected that so many details with reference to the lying-in woman are unnecessary, because of the enormous preponderance of cases in which complete recovery ensues without such treatment, and that to introduce them savors of the performance of some grave surgical operation. So much the more did Dr. Thomas urge them on this very ground, because he believed that the woman who is to bring forth should be treated as though she is to go through a capital operation.

At this point Dr. Thomas made a strong protest against the use of intra-uterine injections as a prophylactic resource, except after very severe operations in the uterine cavity, which rendered the occurrence of septicæmia almost certain.

But suppose that despite all these precautions the poison has entered, what are the most reliable means for checking the advance of the septic disorder? He did not believe there is any specific disease-germ which give rise to puerperal septicæmia. It is probably the same cause which gives rise to septicæmia in the stump after an amputation, or after a wound with compound fracture, or in the lacerated tract after gunshot wound.

A portion of retained placenta or membranes does not give rise to true puerperal septicæmia, but rather to a toxæmia. If the mere presence of decaying material would produce septicæmia without the agency of a specific disease-germ, the disease would develop in healthy country localities.

As soon as the patient is stricken by the poison, certain morbid phenomena develop themselves, such as chill, high temperature, pelvic pain, mental disturbance, headache, pain in the back, and sometimes, though not commonly, nausea and vomiting.

TREATMENT FOR THE CURE.

First.—As soon as the diagnosis is determined upon, all pain and nervous perturbation should be allayed by a

hypodermic injection of morphine, unless there is some special idiosyncrasy in regard to opium, and throughout the attack, whether suffering in mind or body, the hypodermic use of morphine should be repeated sufficiently often to allay it. In this particular case the drug should be used hypodermically, and special care should be taken to use a clean syringe, dipping the needle before its use into a solution of bichloride of mercury (1 to 1,000), which will prevent the formation of abscess.

Second.—Being relieved of pain, spread an india-rubber cloth over the edge of the bed, making it fall into a tub of water rendered antiseptic by the use of carbolic acid (two and one-half per cent.), or bichloride of mercury (1 to 2,000). Then move the patient very gently across the bed, place a pillow under the head, allow each foot to rest upon the side of the tub, and cover with blankets. Then introduce either a Chamberlain glass tube or a Lyman metallic tube, very carefully guided by the index finger, passing it up to the very fundus of the uterus, attach a Davidson syringe, and throw a stream of water with gentle force against the lining membrane of the organ. If there is any suspicion that there remain attached portions of placenta or membranes, they should be carefully removed, using the finger-nails as a curette, as advised by Dr. Wilson, of Baltimore.

There are dangers attending the administration of these injections: first, the entrance of air into the uterine sinuses; second, the production of hemorrhage; third, the danger of forcing fluid directly into the general circulation through the injection tube into the mouth of the sinuses; fourth, convulsions and violent pain, which produce a sudden and baneful influence upon the nervous system, and fifth, the passage of fluid into the peritoneal cavity through the Fallopian tube. All of these may to a very great extent be avoided by careful attention to details. By the use of a large tube, with water not less than 100° F., and using only a moderate degree of force, proceeding gently, cautiously, and slowly, these dangers can be avoided. The tube should not be allowed to fill the os internum or externum completely. If after the use of the injections it is found that the cervical canal hugs the tube too closely, it should be dilated before further injections are practised, and this may be done by the use of either the hard rubber or Barnes dilators. If hemorrhage occurs, persulphate of iron should be added to the antiseptic solution and ergot administered.

The frequency of the administration of the intra-uterine injection should be varied greatly with individual cases. In moderate cases, where the temperature falls readily, only once in five hours may be all that will be required, while in other cases they may be required every three hours, and in bad cases they may be administered as often as every hour. These injections should be administered by the physician always, and should be carried up to the fundus uteri, and every precaution exercised concerning detail. Dr. Thomas favored the intermittent stream. For a number of years he entertained the idea that the continuous flow was most desirable, but on that point he had changed his opinion entirely. Continuous irrigation he regarded as a delusion and a snare. For vaginal irrigation it is an excellent method; nevertheless, in severe cases he preferred to employ continuous irrigation and use the intermittent stream every three hours rather than exhaust the patient by the use of injections as often as seemed desirable. At all events, that plan is best which best cleanses the parturient canal.

Third.—Control the temperature by the use of Townsend's rubber-tube coil, placed over the entire abdomen, from the ensiform cartilage to the symphysis pubis, with ice-water flowing through it. In his service at the Woman's Hospital this means of controlling the temperature is as commonly and freely used as are gargles for diseases of the throat, and thus far no ill-effects had been produced, either in the way of chilliness or by the development of complicating diseases, such as pneumonia, pleurisy, etc. Formerly he relied upon Kibbee's

cot for the same purpose, but had found the coil much more convenient.

Fourth.—Keep the nervous system under the influence of quinine, fifteen grains night and morning, or Warburg's tincture administered in capsule, according to the recommendation of Dr. John T. Metcalf, or by the use of salicylate of soda.

Fifth.—The diet should consist of fluid food, and the staple article should be milk, but animal broths may be alternated with it.

Sixth.—Efficient and abundant assistants. Two nurses are necessary, one for night and the other for day, and at least one extra physician as an assistant, in order to carry out this method of treatment effectually.

In regard to the antiseptic substances used, they have been thymol, boracic acid, salicylic acid, carbolic acid, and bichloride of mercury. The last two are the best, and the bichloride seems to be about to supersede the carbolic acid, and for intra-uterine injections it should be used in the strength of 1 to 2,000.

POINTS OF INTEREST IN CHOREA.¹

By HENRY D. CHAPIN, M.D.,

ATTENDING PHYSICIAN TO THE CLASS FOR DISEASES OF CHILDREN, OUT-DOOR DEPARTMENT, BELLEVUE HOSPITAL.

THE child's service at the Out-door Department of Bellevue Hospital offers an inviting field for the clinical study of chorea. Many of the children brought there for treatment come from the poorest and most neglected classes in the city, among whom bad food and air readily produce the hydremia and other predisposing conditions of this disorder. An analysis of a number of cases that have come under my observation may be of some interest, as repeated clinical observations are needed to verify certain points about this interesting and obscure disease. Perhaps the relation of rheumatism to chorea is one of the most important of these points. Various observers differ as to the closeness of this relation, some considering the rheumatism to act only as a depressing agent in the production of chorea, while others assign to it a much more intimate causative relation. In the histories of thirty-eight cases of chorea, twenty-two were preceded or accompanied by rheumatism, while in the remaining sixteen no such connection could be found. In two of the latter cases, however, one of the parents had been subject to rheumatic attacks. The intensity of the rheumatism varied within very wide limits, sometimes being so pronounced as to leave no doubt as to its character, and again taking on such mild manifestations in the shape of the so-called growing pains as to need careful investigation in order to discover its true nature. Two cases will illustrate:

Rosanna K—, aged thirteen, was brought to me suffering from twitching in all the voluntary muscles. A month previous she had an attack of rheumatism, first in the right knee, then in the left knee, and finally in both ankles, accompanied by pain and some swelling. Two weeks afterward the twitching began on the left side. On examination she was found to have a mitral regurgitant murmur. No history of rheumatism in the family.

Maggie C—, aged nine, complained some about two months ago of wandering pains in legs and ankles. These pains would only last for a few days and then disappear, without preventing her from going about in any way. Two weeks ago her mother noticed that she was getting very fidgety, which ended in well-marked twitching of the face and both arms. She was also found to have mitral insufficiency. Her father and mother have both had rheumatism. In this case I have no doubt that the vague pains complained of were truly rheumatic,

¹ Read by invitation before the New York Neurological Society, November 6, 1883.

in view of all the facts of the history. Assuming that there is a close connection between chorea and rheumatism, it is difficult to determine exactly the relative influences these diseases have upon one another. Thus it is a point of uncertainty whether the same morbid underlying condition predisposes to both rheumatism and chorea, or whether the state of the system left by the rheumatism is one of the principal factors in producing the chorea. I have had several instances in which rheumatism has followed an attack of chorea, and where no previous rheumatic history could be obtained. The following is from my note-book :

April 2, 1883.—Bartholomew C—, aged eight, has always been pretty healthy. Has no history of rheumatism or growing pains, and his father and mother have never been rheumatic. Two weeks ago he seemed to fail somewhat and had some loss of power in his left arm, soon followed by twitching of the left hand and arm. He came to me again on April 12th, saying that a few days previously he had been seized with pains in both knees, which spread up and down his legs. The pains were so severe that he could hardly get up stairs, but they disappeared in about a week and have not troubled him since. Dr. A. R. Robinson, who for some years had one of the children's classes at Bellevue, tells me that in a number of cases he found a chorea to follow rheumatism, in which rigid inquiry seemed to show that a previous rheumatism had not been overlooked. In one case he treated a girl for chorea who had no history of rheumatism, but about two years afterward she was seized with an acute inflammatory affection of the joints. Rahn, in his article on rheumatism in Gerhard's "Handbuch der Kinderkrankheiten," states that Sée mentions five cases in which chorea preceded the rheumatism, and that Roger reports six such cases. Soltmann, in his article on chorea, in this connection quotes Roger, who thinks that chorea and rheumatic affections of the joints, and heart affections, are members of one and the same pathological condition. Therefore he makes a division into chorea rheumatica, chorea cardiaca, and chorea rheumatica-cardiaca, and he is unable to state which process makes the commencement. Often the chorea is primary and the heart affection secondary, or *vice versa*, or the heart affection and the chorea appear at the same time. Again, the chorea may appear first, then the rheumatism, and lastly the heart affection; but generally the rheumatism is first, next the chorea, and the heart affection afterward. I have never seen a case in which cardiac disease followed chorea without any previous rheumatic history. Certain German authors deny any special connection between rheumatism and chorea. Thus Romberg, in the majority of cases, can see no relation between the two diseases, and Soltmann, in the article already mentioned, states that Steiner in two hundred and fifty-two cases found acute inflammatory rheumatism only four times. Rahn, in the "Handbuch der Kinderkrankheiten," concludes, after most careful examination, that there is no special connection between the two diseases. He found in eleven cases of chorea that there were ten in which the heart was normal and in which there was no rheumatism, and thinks that what little connection there may be between the affections varies according to different localities. The statistics published in this paper, together with those previously found, show, I think, that in this locality the connection between the diseases is very close. I have a history of one case in which a girl during the course of three years had three attacks of chorea, each attack being immediately preceded by rheumatism. Most observers have noticed that children with chorea frequently have rheumatic parents, and Rahn himself, in his article, quotes several cases in which rheumatic parents had two children, one of whom had rheumatism and one chorea.

In taking histories of chorea, I think that merely being satisfied with a negative answer when the parent is asked if the child has had rheumatism may not be sufficient

always to arrive at the truth, but that a little more careful investigation should be made to see if such a condition may not have been overlooked. According to Roger it is oftenest the milder or subacute cases of rheumatism that are followed by chorea. Henoch also states that chorea follows, with equal frequency, mild rheumatic conditions. It is well recognized by the authorities that rheumatism in early life has often a much lighter manifestation than in adults. The pain may be but slight and the swelling of the joints absent, or, if present, quickly disappearing. The redness may be trifling, or not exist at all. The temperature is rarely high unless complicated by endocarditis. Children thus affected are seldom confined to the house and often go to school, although constantly complaining some of pain and stiffness—in fact, their parents, when questioned, will say they have had growing pains. I think careful observations will identify in many cases these growing pains with rheumatism. Organic heart disease is by no means infrequent in children, and in many cases I have only been able to get a history of such preceding pains as a cause. While certain infectious diseases may produce endocarditis, yet in children, as in adults, its most frequent cause is rheumatism, and in them this light form is often its only manifestation. I have recently had an interesting case under observation of cardiac disease in a girl of eleven years. Measles and pertussis are the only diseases she has had, but for the last eight months she has complained off and on of some pain and stiffness on exertion in her knees and ankles. There has been no swelling nor redness. A month ago she had such an attack, followed in about a week by pain in the chest, with a gradually developed intense dyspnoea. When I saw her she had marked pericarditis with effusion, with a friction sound at the base. When the fluid had sufficiently subsided I discovered enlargement of the heart, with a double aortic and mitral regurgitant murmur, showing that an endocarditis had followed one of these previous attacks of slight pains. The child dying suddenly, I obtained an autopsy. The pericardium was adherent to about half its extent, and where free both layers were covered by a thick layer of fibrin. The heart muscle was soft and fatty, showing all the evidences of a recent and general myocarditis. The whole endocardium on the left side of the heart was inflamed, with the mitral valves retracted and partially bound down. Fine fibrinous vegetations were seen on the aortic valves. Here, then, there was complete destruction of a heart from a rheumatism whose chief manifestation was a stiffness in the knees. In making a history of growing pains stand for a previous rheumatism it is obvious that a certain limitation and care must be exercised, especially among the lower classes, who are apt carelessly to give an affirmative answer to questions asked by the physician. Thus simple bruises or sores must be eliminated, also the muscular weariness developed in weakly children by over-exercise, the products of tissue metamorphosis being imperfectly removed by the feeble circulation, with resultant irritation and pain. But rheumatic pains usually go from one joint to another, or from one set of muscles to another, and exist independently of any such factors as injury or over-exercise. After all such sources of error have been carefully guarded against by rigid questioning and examination, I think it will remain true that many, perhaps the majority of such pains existing in the child are really rheumatic, and I have so considered them, when other causes could be satisfactorily eliminated.

Among 31 cases there were only 4 in which I could satisfy myself of the existence of organic heart disease. These statistics are somewhat at variance with those of some observers. Thus Radcliffe quotes Dr. Hillier as having noticed in 37 cases of chorea that there was probably organic disease of the heart in 25, and functional derangement in 4, while in 8 only was there no sign of cardiac disturbance. A peculiar functional irritability of the heart was present in most of my cases.

This often took the form of palpitations, and in over half the cases the heart was at times markedly irregular. In 2 cases the pulse was intermittent. In one or two instances young boys confessed to me that they were in the habit of cigarette-smoking, but beyond this I could find no cause, except the chorea, for this arrhythmia of the heart.

In an article in the *Medical News* of August 25, 1883, Henry G. Berkley, M.D., reports an autopsy made in a case of chorea. Upon microscopic investigation he found a pigmentary alteration of the nuclei of the vagi, and suggests that this may afford some explanation of the common implication of the heart in the choreic movements, with or without valvular lesions; that possibly the disease may cause loss of the inhibitory function of the pneumogastric nerve, with resultant irregular action of the heart muscle.

Among 35 cases 18 had a condition of general chorea, 8 had hemichorea on the right side, 5 on the left side, and in 4 the face and both hands and arms were affected, but not the lower extremities. In several instances the first point noticed was that the child could not grasp things well, as seen by dropping plates or other objects. This ataxic condition was soon followed by well-marked twitching. I have notes on two cases of chorea of the respiratory muscles and larynx, and as this subject is not generally noticed in the books, it may be of interest to detail their histories.

The first case is being treated by Dr. Landon Carter Gray, at the Polyclinic, and it is by his kind permission that I have made notes of the case and have the honor of presenting the boy before the Society. Willie D—, aged fifteen, has been troubled with twitching for the last eight years. It began in his hands, and next went to face and head, when it soon became general. His father, mother, and grandmother on his mother's side, have all had rheumatism. The affection of the respiratory muscles came on a year after the chorea began, and has lasted ever since. The sound has remained about the same during the seven years of its continuance. It stops entirely during sleep, and he says it is worse on rainy days. The barking noise is made during expiration. By placing the hands over the chest and back the expiratory muscles are felt suddenly to contract. I made a laryngoscopic examination in his case, and the cords seemed normal. While making the examination there was a sudden spasm of the pharyngeal muscles, the epiglottis was raised, and the adductors quickly contracted the glottis with the production of the peculiar bark. At times there is only a spasmodic action of the expiratory muscles, the adductors of the larynx not being involved, and hence only a sudden rush of air is produced, without the barking sound. There is some paralysis of the soft palate. The general chorea has continued throughout this affection, and three weeks ago he had a slight attack of rheumatism.

Dr. French, of Brooklyn, has kindly given me notes of an interesting case of chorea of the respiratory muscles and larynx which occurred in his practice. Charlie N—, aged nine, has no history of rheumatism. About four years ago he began to have choreic movements in the head and face, shown by twitching of the eyes, grinning, biting the lips, etc. These movements lasted for several months and then stopped for an entire winter. His mother then noticed that he began to make a peculiar involuntary sound. Upon consulting the doctor, he found the child to be suffering from choreic spasms of the muscles of the chest, abdomen, neck, and larynx, producing a forced expiration with a peculiar squeaking sound. The doctor says this sound was as much like the squeak of a young turkey as anything else. It would occur at the beginning, middle, or end of the expiration, which would be suddenly interrupted. At times as many as four distinct sounds were heard with one expiration, and whenever this happened there was invariably only one sound produced during the next expiration.

Upon the beginning of these sounds the face movements had ceased, but on one occasion they returned for two days, when the laryngeal sounds ceased. When the head and face movements again stopped, the sounds began again. In fact a peculiar feature of the case was that whenever there was twitching in any other part of the body the laryngeal sounds would cease, as if the disease were unable to institute the choreic contractions in the respiratory and laryngeal muscles and the general voluntary muscles at the same time. On laryngoscopic examination the motions of the cords were plainly seen. The sounds always ceased entirely at night. A rough scraping of the throat frequently alternated with these sounds. The mucous membrane of the larynx grew somewhat congested as a result of this scraping. The sounds all disappeared after three months' general treatment, and have not returned, except very infrequently. True laryngeal chorea has no sound, as no current of air is present to cause the cords to vibrate. As soon as a sound or bark is produced it ceases to be purely laryngeal, as the expiratory muscles are involved. Their spasmodic contractions can be felt by the hand. I think the only case of true laryngeal chorea ever reported is by Dr. Knight, of Boston. In a woman of forty-two years the vocal cords were driven together with such force that he could hear them strike, but no sound was produced.

In only seven out of thirty-three cases could I get a history of such a cause of chorea as fright or mental excitement, and in four of these there was an accompanying rheumatic history. As an example, Mary O'B—, aged eleven years, had come to me six months before, suffering from rheumatism in both knees and legs. Although there was no noticeable swelling when I saw her, she could scarcely walk; she recovered under treatment, but returned in a few months affected by a general chorea. I learned that her father was a confirmed drunkard, and had recently exercised much terrorism over the girl. In three cases, however, there was nothing but pure fright to account for the chorea. Thus, Lizzie S—, aged ten years, had always been pretty healthy, and there was no history of rheumatism in herself or family. Upon a certain occasion a teacher had punished her frequently for some offence, which was soon followed by a general twitching. As a general rule, I have noticed that children attacked by chorea are those who are intellectually rather bright than otherwise. If they are stupid, it is probably a psychical change induced by the disease, as inquiry often elicits that they were studiously inclined and ambitious of standing well at school. Radcliffe states that children attacked by chorea are usually distinguished by vivacity and restlessness of disposition, although there may be a vacancy of countenance resulting from a semiparalyzed condition of the features.

With reference to age and sex, I have statistics of 324 cases. Out of these, 288 have come for treatment to the Out-door Department of Bellevue Hospital since April, 1878, and I am indebted to the courtesy of Dr. C. L. Dana for 30 out of the remaining 36 cases. Among these 324 patients, 228 were girls and 96 were boys. M. Sée in his 531 cases had 393 girls and 138 boys. All statistics show the girls to largely preponderate in this disease.

The following is the record of the ages: 3 years and under, 5 cases; at 4 years, 3 cases; at 5 years, 14 cases; at 6 years, 19 cases; at 7 years, 35 cases; at 8 years, 53 cases; at 9 years, 40 cases; at 10 years, 39 cases; at 11 years, 41 cases; at 12 years, 34 cases; at 13 years, 20 cases; at 14 years, 16 cases; at 15 years, 5 cases.

The ages most frequently attacked, according to these figures, are, first, 8, next 11, next 9, next 10, next 7 years, and so on. From the histories of the 531 cases that were collected by M. Sée at the Children's Hospital, Paris, he finds that the greatest frequency of chorea is between the 6th and 10th years. Of the children under

3 years, 1 was 7 months and another 1 year old. Rare cases of congenital chorea, and that observed in infants at the breast, have been occasionally recorded. Von Ziemssen quotes Richter as mentioning two cases of congenital chorea occurring in girls whose mothers had received a severe fright late in pregnancy. From their birth the children were attacked with clonic spasms, which gradually almost wholly disappeared. In order to determine whether different seasons had any influencing effect on these cases, I have taken from the entry-book at the dispensary the number of patients with chorea registered for the last two years, at different periods in the year, with the following result: From November 1, 1881, to May 1, 1882, 30 cases; from May 1, 1882, to November 1, 1882, 34 cases; from November 1, 1882, to May 1, 1883, 36 cases; from May 1, 1883, to November 1, 1883, 29 cases. These figures show about the same ratio for all parts of the year.

With reference to treatment, I have been guided by a routine, which, although rather unvarying, has generally been successful. It is rare in an out-patient service to see those severe and aggravated cases that seem to defy all kinds of therapeutics, and none of my cases have been of this character. They have been of a mild or moderately severe type, and have usually yielded to the general combination of arsenic and iron. In children of from eight to ten years I have started with five drops of Fowler's solution, combined in a prescription with about five grains of the citrate of iron and quinine. If within a week or so there have been no signs of improvement, I have slightly increased the dose of arsenic, but I have never been obliged to push it to toxic doses. In other cases, where there has been much anæmia, I have given ten drops of the tincture of the chloride of iron with the arsenic, largely diluted with water, after each meal. I have also directed the children to be removed from school, and freed from all mental restraint; also to have as generous a diet as possible, and plenty of out-door exercise.

The expectant plan of treatment, based upon perfect hygiene and the best diet, has sometimes been advocated for chorea, to the complete exclusion of medicinal treatment. In the "Proceedings of the Kings County Medical Society for December, 1878," Dr. Landon Carter Gray makes a comparison of the arsenical with the expectant plan of treatment. A number of cases were kept under observation from the beginning of treatment to the entire disappearance of all symptoms. The treatment was entirely arsenical, no directions being given as to hygiene or food. The results were then compared with a number of cases published by Drs. Gray and Tuckwell in support of the expectant plan, when he finds a balance of twelve days in favor of the arsenical treatment. While arsenic is undoubtedly the best for routine treatment, certain other measures may hasten the cure. Thus, if the child is vigorous enough, the cold plunge may be employed; also cold affusions to the nape of the neck and along the spine, with frictions. Rhythmical gymnastic exercise is sometimes beneficial. Dr. C. L. Dana, in a paper read at the last meeting of the American Neurological Association, claims that he has found anodal galvanization a valuable adjunct in the treatment of chorea. It was found that by applying it daily for a week or ten days, with arsenic, he materially shortened the duration of the disease. His method of application is as follows: "A large sponge electrode of flexible brass, four by two inches, is thoroughly moistened with salt water. The hair of the patient is also thoroughly wetted, and the electrode applied over the sides of the head, above the ear. In hemichorea it need only be applied over the side opposite to the one affected. The other electrode is placed in the hand of the affected side. The electrode upon the scalp is made positive, and a stable current of three to six Stöhrer's, four to eight Daniell's cells is used."

A NEW METHOD OF STAINING BACILLUS TUBERCULOSIS.

By T. J. BURRILL, M.D.,

CHAMPAIGN, ILL.

HAVING had considerable experience in the use of the alcoholic solutions of aniline dyes for staining bacteria, and having for some months used solutions in glycerine instead, I have come to much prefer the latter. Evaporation of the solvent is avoided, and in consequence a freedom from vexatious precipitations is secured, and more uniform and reliable results are obtained. There is, moreover, with the alcoholic mixtures a tendency to "creep," or "run," by which one is liable to have stained more than he wishes—fingers, instruments, table, etc.

From these things the glycerine mixtures are practically free, and there are no compensating drawbacks. For staining *bacillus tuberculosis* the following is confidently commended as preferable to the materials and methods heretofore in use. Take glycerine, 20 parts; fuchsin,¹ 3 parts; aniline oil, 2 parts; carbolic acid, 2 parts.

The solution is readily and speedily effected, with no danger of precipitation, and can be kept in stock without risk of deterioration. When wanted for use, put about two drops into a watch-glass (a small pomatum-pot is better) full of water and gently shake or stir. Just here there is some danger of precipitating the coloring matter, but the difficulty is easily avoided by gentle instead of vigorous stirring. After the stain is once dissolved in the water no further trouble occurs; if any evaporation takes place by being left too long, it is the water that goes, not the main solvent. The color should now be a light, translucent red, much too diffuse for writing-ink. Put in the smeared cover-glass, after passing it a few times through a flame, and leave it, at the ordinary temperature of a comfortable room, half an hour. If, however, quicker results are desired, boil a little water in a test-tube and put in about double the above indicated amount of the glycerine mixture, letting it run down the side of the tube, gently shake until absorbed, and pour out the hot liquid into a convenient dish and at once put in the cover with sputum. Without further attention to the temperature the stain will be effected within two minutes; but the result is not quite so good, especially for permanent mounts, as by the slower process.

After staining put the cover into nitric (or hydrochloric) acid and water, one part to four, until decolorized, say one minute; wash in water and examine, or dry and mount in balsam.

If it is desired to color the ground material, which is not necessary, put on the decolorized and washed glass a drop of aniline blue in glycerine; after one minute wash again in water and proceed as before.

Almost any objective, from one-fourth inch up will show the bacilli if sufficient attention is paid to the illumination.

SALTS OF NICKEL.—Dr. J. M. Da Costa has been testing the therapeutic value of the salts of nickel. The sulphate proved of some value in obstinate diarrhoea. The bromide, however, is the most valuable of all, and will probably take a permanent place in the materia medica. Its action is similar to the other bromides, but a much smaller dose suffices. Five to seven and a half grains is an average dose, and ten grains is a decided one. It relieves congestive forms of headache and quiets the system generally. In epilepsy it does quite as well as other bromides, but, as above mentioned, a much smaller dose suffices.

GENERAL PREVALENCE OF SMALL-POX IN MEXICO.—The *Mexican Financier* warns foreigners that, before they come to Mexico, they should be vaccinated, as small-pox is generally prevalent in the country.

ALFRED STILLÉ.—*Local*.—Ice in mouth and on neck first stages. Alum or tannin by insufflation; muriatic acid by a brush; potassium chlorate; tincture iodine; lactic acid is a good solvent of the membrane; carbolic acid; potassium permanganate. *General* treatment is the indication, as the membrane will return till the cause is removed. Emetics may be advantageous in the early stage. "Supporting of nature is the only way to treat;" nature will eliminate the poison; in grave forms, stimulate; alcohol and stimulant doses of quinia; tincture of chloride of iron is absorbed, constricts the blood-vessels, and previous exudation; food is the greatest of all indications; opium diminishes waste and nervousness; it also aids in the appropriation of other stimulants; alcohol can be borne in large doses; fluid beef, milk, farinacea; Huxham's tincture. In cases of medium intensity, give tonics rather than stimulants. Tracheotomy is fatal in about three-fourths of the cases. It is advisable under favorable circumstances.

J. SOLIS COHEN.—The two main indications consist: 1, in keeping up a supply of nourishment and stimulants, and 2, in providing for the detachment and discharge of the morbid accumulations when they threaten to occlude the air-passages. The sick room must be systematically disinfected. This is done by the free use of sprays of carbolic or sulphuric acid. Solutions of the sulphate of iron or some other disinfectant are kept in all the vessels which are brought into the sick-room to receive the discharges, the soiled clothing, refuse food, and slops of the patient.

He regards the chlorine compounds as of more efficacy in diphtheria than all other remedies. Of these he prefers the tincture of the chloride of iron, which must be administered at frequent intervals and in large doses—from five to thirty drops, according to age and vigor of patient, should be given from every half hour to every second hour as the case may be. It is given in glycerine and water, or in diluted syrup of lemon. Dr. Cohen prescribes chlorate of potassium very frequently in this disease—in the form of *chlorine* mixture (made of an equal number of grains of the chlorate and of drops of hydrochloric acid, in plain or aromatic water, or in the infusion of quassia). He always suspends the use of this remedy when there are any symptoms of renal irritation produced by it.

He administers the hydrochlorate of quinia (in preference to the sulphate) as a tonic, antipyretic, neurotic, and antiseptic. It is to be given in decided doses. When deglutition is painful it is given by enema, with proper augmentation of the dose.

Alcohol, in the form of strong wine, or as brandy or rum, is regarded as of the utmost importance when the system begins to give way. It should be given after the earliest manifestations of decided loss of vigor. At this stage it is of more importance for the time being than any remedial agent. From $f\frac{3}{4}$ ss. to $f\frac{3}{4}$ j. of brandy are to be given at intervals of from fifteen minutes up to three hours. As long as it is well borne it may be given to any extent short of intoxication. Children readily take a sort of syrup of brandy made by burning it beneath a lump of sugar, which becomes melted in the process. At moments of sinking he regards carbonate of ammonium as valuable. He gives from two to ten grains by the mouth, in syrup of acacia, or from eight to forty grains by the rectum. At moments of collapse the ammonia is given by intravenous injection.

The sore throat is treated by pellets of ice placed in the mouth and renewed more or less cautiously. The use of ice-compresses is not approved. It is thought better to apply warm cotton batting, spongio-pilin, or an actual cataplasm, or to anoint the neck with oil, lard, or cosmoline, care being taken not to abrade the cuticle

lest local infection arise as a complication. Morphia is administered when great pain arises.

Morbid products in the pharynx and nasal passages undergoing detachment should be promptly removed. This morbid product is kept diffuent as much as possible by maintaining an excess of humidity in the atmosphere of the room by keeping a steaming vessel of water on the stove. The uninvaded tissue should never be cauterized. Applications of the tincture of the chloride of iron should be made to the pseudo-membrane with a swab of cotton or sponge. After this application the attempt may be made to remove the deposit by gargle, spray douche, or syringe; employing lime-water as the medium. Forcible removal of the deposit is not regarded as judicious.

When the larynx is invaded Dr. Cohen keeps a constant stream of steam in motion directed over the patient's face. Whenever the respiration becomes obstructed, a few pieces of lime about the size of the fist are slacked by the bedside every hour or so, covering the vessel in which they are slacked with a hood of stiff paper, so as to direct the steam and particles of lime toward the mouth of the patient.

The use of emetics is indicated in children to provoke expectoration from the air-passages in the act of vomiting; but the same indication does not occur in adults who are able to expectorate voluntarily. If successful, the emetic may be repeated, at intervals of six hours, as long as the indications continue to recur. Alum, ipecac, and turpeth mineral are the most reliable agents, and may be tried in the order named; adhering to the alum if it prove efficient. Emesis should not be carried too far, or be repeated if ineffectual, as it exhausts the power of the system without any compensation in the discharge of morbid products.

Should asphyxia be threatened from accumulations in the larynx or trachea, tracheotomy is indicated, and, though most frequently unsuccessful in averting death, it facilitates due access of atmospheric air to the lungs, and often saves lives that would otherwise be lost. The most careful attention is required after tracheotomy to keep the artificial passage clear. The stimulating treatment and the lime inhalations should not be discontinued. The two main indications for favorable prognosis after tracheotomy are desire for food and ability to expectorate. All treatment should be subservient to facilitating these great ends.

BARTHOW believes that there are two objects to be kept in view in the treatment of diphtheria:

1. To modify the course and shorten the duration of the disease; 2, to obviate the tendency to death.

First head.—The application of topical agents to the fauces and the administration of internal remedies according to symptoms.

He entirely disapproves of caustic and acid applications as inviting the disease to the adjacent portions of the mucous membrane by destroying the epithelium. He does not think much of the value of benzoate of sodium. The application of sulphur, in the form of powder, by insufflation or by blowing it over the whole diseased surface as far as it can be reached, he believes to be a good treatment. He regards lime-water and lactic acid as of value as solvents. Some pieces of freshly burned lime are put in water, and the patient directed to breathe the vapor as it rises, or a solution of lactic acid strong enough to taste distinctly sour is freely applied to the throat by a large mop. He places no value in the use of chlorate of potassium or tincture of the chloride of iron as faucial remedies. When gangrenous sloughs are thrown off from the throat, carbolic acid is indicated, a one per cent. solution—not stronger than one per cent. This solution may be applied either by mop or syringe. When the exudation extends into the nares, the spray of a one per cent. solution of carbolic acid is gently thrown into them and kept up until the two canals are pervious, thus preventing the extension

and decomposition of morbid materials and the consequent swelling of the deep cervical glands and possible development of septicæmia. It is only when the exudation extends into the nares that much good can be accomplished by topical applications—so thinks Dr. Bartholow.

Second head.—The prevention of the diffusion of the morbid agent, of the development of septicæmia, and of failure of the heart.—With the earliest appearance of an exudation in the fauces, from two to ten grains of the bromide of ammonium are given every three hours. It is believed that the diffusion of this agent through the mucous membrane of the respiratory organs, and so out of the mouth, detaches the exudation. To prevent septic decomposition he advises the use of a drop or two of Lugol's solution in water every hour or two. This drug is to be given when the exudation is fully developed and spreading. He uses alcohol steadily, pushing it in large doses as an antiseptic agent. Quinia is also considered valuable in this same connection. Dr. Bartholow does not believe in the extraordinary powers of chlorate of potassium in this disease, as claimed by many. He fears its injurious effects on the kidneys.

As food, milk, egg-nog, and beef-tea are given freely about every three hours.

ABRAHAM JACOBI sums up the treatment as follows: Every case should be treated on general principles with symptomatics, roborants, stimulants, febrifuges, externally, internally, or hypodermically.

The uncertainty of the termination and the frequency of collapse, or sepsis, prohibit procrastination. Waiting long means often waiting too long. Alcohol is a very important adjuvant and remedy.

The dose must often be apparently large, from two to twelve ounces daily, according to the circumstances.

Depletion is absolutely contra-indicated. Debilitating complications, such as diarrhœa, must be stopped instantly. Stomatitis, chronic pharyngitis, hypertrophy of the tonsils, glandular enlargements, must be relieved or removed preventively. Acute catarrh of the mouth and pharynx requires the use of potassium or sodium chlorate, in doses not exceeding a scruple daily for a child of a year, one to two drachms for an adult. The single doses must be small and very frequent—every hour, half, or quarter hour. Large doses are dangerous, result often in nephritis, and have proved fatal. The main indication in local diphtheria is local disinfection. To disinfect the blood effectively we have no means. Salicylic acid changes into a salicylate which is no longer a disinfectant. The amounts of disinfectants required to destroy bacteria are so great that the living body could not endure them. But the discipline of the house, school, and social intercourse can be so modified as to prevent the spreading of an epidemic. The inhalation of steam is very useful in catarrh of the respiratory organs, and also in inflammatory and diphtheritic affections. In fibrinous tracheo-bronchitis it has proved quite successful. But it may also prove dangerous by excluding oxygen and overheating the room or tent. Drinking large quantities of water, with or without stimulants, also excites action of the muciparous glands and aids in macerating membranes. The internal use of ice, and its local application to the affected parts, can be very useful. But the cases must be selected for each and any of the remedial agents and applications. The use of baths and the cold and hot pack is controlled by general indications. The usefulness of lime-water and lactic acid has been greatly overestimated. Glycerine is a valuable adjuvant, both internally and externally, but nothing more. Turpentine inhalations are deserving of further trials, though they are more effective in purely inflammatory than in diphtheritic processes. Inhalations of chloride of ammonium act favorably in catarrhal and inflammatory conditions, and deserve a trial for the purpose of aiding maceration of membranes. Mercurials are contra-indicated in the septic and gangrenous forms of diphtheria, but in those

which assume the purely inflammatory character, with less constitutional debility and collapse, as in sporadic croup or in fibrinous tracheo-bronchitis, some reliable clinicians claim good results. Astringents, such as alum, do not work favorably. Chloride of iron is among the most reliable of antiseptic and astringent agents. Small doses at long intervals are quite useless. Moderate doses frequently repeated have a satisfactory general and local effect. A child of a year must take at least a drachm daily; a child of three or four years, from two to three drachms. The same or larger doses for an adult. The chloride is to be mixed with water and glycerine in various proportions, so that a dose is taken every hour, every half-hour, every ten minutes. Thus the local applications to the throat become almost superfluous. Potassium or sodium chlorate, half a drachm daily, may be added with advantage. Carbolic acid is useful both in local and internal administration. According to the end to be reached, it may be used either in concentrated form or in a one per cent. solution. Internally, in doses of a few grains to half a drachm daily. Salicylic acid acts as a caustic when concentrated; in moderate solutions it destroys fetor; salicylates are anti-febrile only. The anti-febrile effects of quinia are not so favorable in infectious as in inflammatory fevers; its antiseptic action is not satisfactory in practice. Deliquescent caustics are dangerous. Injury of the healthy mucous membrane must be avoided. Mineral acids, and particularly carbolic acid, when their application can be limited to the desired locality, are preferable. Bromide, both internally and externally, is warmly recommended by Wm. H. Thompson. Boric acid, in concentrated and milder solutions, has been recommended as a local application to membranous deposits generally, and to the diphtheritic conjunctiva in particular. Membranes must not be torn off, and not removed unless they are nearly detached. Caustics are contra-indicated, except where their application can be limited to the diseased surface. No healthy part must be torn. Swelled lymph glands require ice, iodine, iodoform, mercury, poultices, incision, carbolic acid, according to circumstances, and at all events frequent and careful disinfection of the mucous membrane from which their irritation originates. Diphtheria of the nose is apt to be fatal unless careful treatment is commenced at once. It consists of persistent disinfection of the nares and pharynx by injections. The tendency to sepsis forbids a long intermission of them. They must be continued day and night, for one to several days, no matter whether the glandular swelling be considerable or not. Laryngeal diphtheria proves fatal in almost every case, unless tracheotomy be performed. It is less successful the more the epidemic or case bears a septic character. Emetics are useful for the removal of the half-detached membranes. Diphtheritic paralysis requires good and careful feeding—iron, strychnia, the faradic or galvanic currents, friction, hot bathing. Urgent cases indicate the hypodermic administration of strychnia. Diphtheritic conjunctivitis is benefited by ice and boracic acid; cutaneous diphtheria by local cauterization and disinfection, besides general treatment.

C. E. BILLINGTON recommends the following prescriptions:

No. 1.—Iron and Glycerine Mixture.

R. Tinct. ferri chloridi f 3 j.
Glycerinæ,
Aquæ āā f 3 j.

M. Sig.—A teaspoonful of this and of No. 2, alternately, every half-hour through the day.

No. 2.—Chlorate of Potassium Mixture.

R. Potassii chlorat 3 ss.
Glycerinæ f 3 ss.
Aquæ calcis f 3 ijss.

M. Sig.—A teaspoonful of this and of No. 1, alternately, every half-hour through the day.

No. 3.—*Spray Mixture.*

R. Acid. carbol. ℥ xv.
 Aquæ calcis f 5vj.

M. Sig.—To be used with a small hand atomizer.

The patient is allowed to sleep for an hour or two at a time at night. When awake, doses of Nos. 1 and 2 are alternated every half-hour. The throat is sprayed with No. 3 for several minutes at a time, whenever Nos. 1 and 2 are given. In spraying, the mouth is opened widely.

Where there is nasal implication the nose is thoroughly syringed out with warm or tepid salt-water, once, twice, or three times a day. This syringing is done with the patient's head inclined forward; a two-ounce hard-rubber ear syringe is used.

Dr. Billington never applies any brush or swab to the throat. He sometimes throws a drachm of No. 1, with a syringe, directly against the affected surface in the throat. He does not give quinia or any other unpleasant medicine to children. He does not give alcoholic stimulants except where a child, who cannot be induced to take other nourishment, will take weak milk-punch or egg-nog.

The patient is nourished with an abundance of cold milk, given frequently, to which a little lime-water is often advantageously added. When the stage of extreme exhaustion has been reached in bad cases the juice squeezed from beefsteak is given.

Progress of Medical Science.

MUSCULAR ATROPHY IN RHEUMATISM OF THE JOINTS.

—Dr. Luigi Petrone (*Lo Sperimentale*) has collected a few cases in which muscular atrophy accompanied or followed immediately upon rheumatic inflammation of the larger joints, especially of the shoulder and knee. The deltoid and triceps suffered especially. The atrophy showed itself about the beginning of the second week after the articular pain; sometimes there seemed to him more loss of power than atrophy, sometimes the reverse. Similar muscular atrophy was noticed by M. Voltat after traumatic injury of the joints (*Archives Générales*, 1879); in some cases occurring more rapidly, even within twenty-four hours of the injury. This led Dr. Petrone to a series of experiments, consisting in the artificial induction of acute synovitis in animals. He found on post-mortem examination, within ten or twelve days of the experiments, that the muscles in the neighborhood of the inflamed joint had lost ten to thirty per cent. of their weight. The nerves showed nothing abnormal. He does not pretend to determine the method of the influence of the joint-affection on the surrounding muscles, but urges that the effects are too rapid to be explained either by the atrophy of disuse, or by Vulpian's hypothesis ("Leçons sur l'Appareil vasomoteur," vol. ii.) that the irritation of the articular nerve produces an effect on the gray matter of the spinal cord which leads to the muscular atrophy.

GELSEMIUM IN INTERMITTENT FEVER.—Dr. McKay, in the *St. Louis Courier of Medicine*, October, 1883, says that he uses gelsemium in chills, with as much confidence as he formerly used bark. If the stomach has been prepared for it by the use of a pill or two, or three, composed of podophyllin and leptandrin, with solid extract of hyoscyamus, one-half or three-fourths of a grain each, one at a time, gelsemium will arrest chills as often as any other remedy. He gives the fluid extract in one-fourth to one-half drop doses once in twenty or thirty minutes, beginning usually three hours or so before the time of the expected chill. This for adults; children much less. If this does not succeed, he does not increase the dose, but lessens it. He usually prepares the medicine for use by putting, say, ten drops into a teacup or tumbler, if for immediate use, and measuring in three or four teaspoonfuls of water to each drop,

and giving in teaspoonful doses as stated above. If to be kept for a few days, he puts in camphor or pepper-mint-water, which helps to keep it sweet; or, where there is much headache, he puts in bromide of potassium, and that helps to keep it. If glycerine is added it will keep indefinitely. The medicine, prepared in this way, will rarely fail to quiet any nervous chill or rigor after it is fairly under way. In such cases he gives it sometimes as often as every five minutes in severe cases, and it has never failed him.

DIPHTHERITIC NEPHRITIS.—According to Professor Fürbringer cases of pure diphtheritic nephritis without passive congestion may be divided into three classes: First, kidneys which appear normal to the naked eye with an anemic cortex. In these the essential and almost the only histological change is parenchymatous degeneration of the epithelium in the cortical tubules. This is an abortive form, closely allied to the febrile kidney. In the second form the cortex of the kidney appears slightly increased, and is pale and turbid looking on section. The degeneration of the cells in this form is both more intense and more extensive, and extends to the epithelial covering of the glomeruli. Alterations of the interstitial substance are beginning; the medullary tubules are sometimes catarrhal; there are no vascular lesions. The third form is the large yellow kidney, a form that is parallel to the hemorrhagic kidney of scarlet fever. In this form there is extensive fatty degeneration of the parenchyma and well marked alterations of the stroma.—*Virchow's Archiv*, vol. xcii., March, 1883.

RIGORS FOLLOWING INTRA-UTERINE IRRIGATION.

Dr. Fasola (*Annali di Ostetricia, Ginecologia, e Pediatria*) examines one of the accidents of intra-uterine irrigation in the puerperal state—rigors. This accident is not rare, since it was observed twenty-four times in two hundred in which irrigation was used in the clinic of Turin, in the scholastic year 1881–82. Of these observations he reports eight, those, that is, in which the appearance of the rigor after irrigation was marked and characteristic. He draws the following conclusions: 1. Disinfectant intra-uterine irrigations practised in the puerperal processes of septic endometritis, with offensive lochia, etc., are frequently followed by rigors. 2. The rigor is so much the less intense as the offensiveness of the lochia is less, and the earlier the local treatment is begun; and in these cases it frequently only amounts to a sense of chilliness rather than to a decided rigor. 3. It generally appears after the first irrigations, often after the evening irrigation; it is not always repeated. 4. The rigor is followed by elevation of temperature; but this is of short duration and is followed by a fall, sometimes great in slight cases, when the temperature did not exceed 101.3° F. before the irrigation, not uncommonly to the normal. 5. The rigor and the rise of temperature never gave rise to further alarming symptoms. He attributes the rigor to the accidental absorption of septic materials, favored or promoted by the mechanical action of the irrigation, removal of thrombi, laceration of vessels, etc. He does not consider that it in any way is to be considered as a reason why endo-uterine irrigation should be discontinued.

MEAT AS A FOOD.—The value of meat as a food is due in a degree to its heat-producing properties, though in this respect it is surpassed by fatty and amyloid substances. It is as a tissue-building material, and as an excitant of assimilative changes in the tissues, both with regard to itself and to non-nitrogenous foods, that it is most useful. It is stimulant as well as nutritive, and it therefore holds a deservedly high place in the daily dietary. Experiment has shown that three-quarters of a pound of lean meat fairly represents the quantity per diem which, taken with other less nitrogenous matter, suffices to maintain a person of average size and weight in a normal state of health. Some there are who largely exceed this standard, eating freely of meat at every meal,

and living all the time quiet, sedentary lives. Such carnivorous feeders sooner or later pay a penalty by suffering attacks of gout or other disorders of indulgence. But it is equally important to note that many others, especially women, healthy in all points but for their innutrition, are apt to err as far on the other side. Thus one meets with people who consume about a pound of butcher's meat in a week, or not even that. This fact has been fully brought out by Dr. Graily Hewitt, in his address to the Obstetrical Section at the recent meeting of the British Medical Association. He has likewise with much probability assigned this defect of diet as the chief cause of that general "weakness" which is so common among the antecedents of uterine displacement. The experience of many practitioners will confirm his observation. Different causes are at work to produce this kind of underfeeding—too rigid domestic economy, theoretical prejudices, the fastidious disinclination for food which comes of a languid in-door life without sufficient bodily exercise, tight lacing perhaps, and many more. These difficulties are all more or less removable, unless, indeed, where absolute poverty forms the impediment. No effort should be spared to remove them. The advantages derived from a diet containing a fair amount of solid animal food could not be obtained from a purely vegetable or milk regimen without either unnecessarily burdening the digestive system with much surplus material, or, on the other hand, requiring such revolutionary changes as to quantity and quality of food and times of eating as would probably altogether prevent its general adoption, even were that desirable, into household management. In our opinion, such changes are not desirable, as being inadequate to secure their purpose.—*The Lancet*, September 15, 1883.

THE SECRETION OF BILE.—Baldi has made an experimental investigation of this subject (*Lo Sperimentale*), which again shows the singular irregularity of the flow of the bile. This alone suffices to distinguish it from the other digestive secretions. The observations of the author, so far, tend to prove that the liver, as the secretory organ of the bile, must be considered as an emunctory for the waste materials of the different tissues destined to be expelled. This accords with the researches of Schiff, who has shown that the bile poured into the intestine is in part reabsorbed and taken back to the liver by the portal vein, to be again excreted and returned to the intestine. Some observers doubt if the biliary matters absorbed into the blood pass again in the secretion of the liver, thinking it possible that they may serve only to excite increased secretion without passing out again by the liver. Having repeated Schiff's experiment of injecting bile into the stomach and directly into the blood, the author shows that the liver, rather than the kidneys, expels the biliary matters from the blood. When ox-bile was injected into the stomach, the secretion of bile increased enormously, the bile having taken the green color of the ox-bile. The same happened when the bile was injected into the blood direct, while the urine showed no trace of biliary acids by Pettenkofer's test. All the bile was expelled by the liver, and not a trace by the kidneys. Admitting that the biliary acids (the only true specific elements of bile) are the exclusive products of the hepatic cells—and this remains to be directly proved—the fact is nevertheless true that the biliary secretion is distinguished in a characteristic manner from the other digestive fluids, by the irregularity of its flow and by its independence of any decided exciting influence of food or medicine. It presents instead many points of contact with the urinary secretion; both depend essentially on the collective waste of the organism, the liver having an excretory faculty for the biliary materials, just as the kidneys have for the urinary materials.

RENAL OPERATIONS.—Mr. Lucas, in a recent discussion on the surgical diseases of the kidney and the operations for their relief (*London Medical Record*, October 15, 1883), commenced by saying that the greatest ad-

vances in the treatment which had taken place of late years were those made in the indefinite border-land which separates medicine from surgery. It was in this barren and desolate tract that we must look for fresh discoveries. Ovariectomy and the various operations upon the intestines and stomach he put forward as instances of work recently advanced in this territory; but he claimed, as the most remarkable incident of this decade, the sudden light which fell upon the profession in its relation to renal disease and the rapid growth and recognition of renal surgery. The credit of having awakened a new interest in renal disease, and of having, by experiment on the lower animals, made sure of his ground, was due to the late Professor Simon of Heidelberg, who in 1869 successfully performed nephrectomy for the cure of a fistula of the ureter following ovariectomy. Since then, extirpation of the kidney has been performed upward of a hundred times. In concluding his suggestive remarks Mr. Lucas recommended for the lumbar operation a combination of two incisions which he had employed as giving the most room, viz., an oblique incision higher than the colotomy incision, within about half an inch of the last rib and parallel with it, and a vertical incision on the outer margin of the quadratus lumborum, extending from the upper edge of the last rib to the iliac crest. For the transperitoneal operation, Langenbuch's incision external to the rectus muscle is to be preferred to the median incision, as it enables the operator better to reach the kidney through the outer layer of meso colon. In conclusion, he urged that antiseptic explorations of the kidney through the loin is a simple and not at all a dangerous operation, which may be undertaken without anxiety in any case where calculus is suspected; that it is generally wiser to tap and drain fluid tumors of the kidney before proceeding to remove the diseased organ; that when nephrectomy is decided upon, the extraperitoneal operation through the loin should always be chosen for any tumor which it is possible to withdraw through the limited space at disposal; finally, if this course be adopted the transperitoneal operation will be reserved for large solid tumors and, perhaps, some floating kidneys.

SPASTIC SPINAL PARALYSIS.—Dr. N. Weiss relates the following cases (*Prager Med. Woch.*, 1883): 1. A man, aged fifty-five, suffered from weakness and stiffness of his lower extremities, the upper limbs remaining unaffected. The only other symptom that he presented was slowness of speech. After death, symmetrical sclerosis of the lateral columns was found. There were also two deposits in the brain—one a cyst of the size of a walnut, on the right side in the posterior part of the corpus striatum, reaching in the corpus dentatum. On the other side a deposit of cell-growth, of the size of a hazel-nut, was found in the corpus striatum. 2. A man, aged thirty-one, having experienced pain and sense of constriction in his limbs, found difficulty in walking. Some weeks afterward, symptoms of pressure on the cord appeared. Caries of the sixth, seventh, and eighth dorsal vertebrae was found after death, with secondary degeneration of the lateral columns of the spinal cord. 3. A man, aged twenty-nine, had only for a short period before his death the symptoms of spastic paralysis. Nerve-stretching had been employed. Death occurred in nine days; on post-mortem examination, multiple cerebro-spinal sclerosis was found.

GLYCERINE IN SKIN DISEASES.—M. Desguin, of Antwerp, gives glycerine internally in certain forms of skin disease with, it is said, marked success, especially in acne punctata and the furuncular diathesis. He commences with four drachms daily, and gradually increases the dose. He states that the secretion of the cutaneous glands, which is thick and irritating in these diseases, becomes more liquid, and cutaneous irritation is notably lessened. During convalescence from scarlet fever he believes that it facilitates desquamation.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, December 15, 1883.

LAPAROTOMY FOR HEMORRHAGE IN TUBAL PREGNANCY.

TWENTY years ago, when the late Dr. Stephen Rogers, of this city, wrote his elaborate paper on extra-uterine foetation, and advised laparotomy for the arrest of hemorrhage occasioned by the rupture of the Fallopian tube, he took a long look ahead. He was so convinced that the operation was a proper one that he condemned, in very decided terms, the surgeon who should hesitate to perform it when the opportunity offered. It was a radical measure, he contended, but under the circumstances perfectly justifiable, as such hemorrhage was sure to result fatally unless a desperate chance was taken. The acknowledged difficulty was in arriving at a correct diagnosis in time to give the patient the benefit of the operation. With the recent advances in abdominal surgery, and the remarkable success which has crowned the bold invasion of the peritoneal cavity, surgeons have accustomed themselves to believe that any operative procedure in that region may be safely undertaken. For this reason, perhaps, more than any other, Dr. Rogers' suggestion grew in importance and commended itself as a measure which might challenge a practical vindication. At least for the past few years operators have held themselves in readiness for their first case, and have so far agreed with the opinion of Dr. Rogers that they have been willing to assume the risks, great as they are. We believe that to Dr. Charles K. Briddon, of this city, belongs the credit of being the first to perform this operation. The patient was a young married woman, twenty-seven years of age, the mother of two children, the youngest three years of age. She had missed one menstrual period, and at the time of the second was seized with a severe colicky pain in the lower portion of the abdomen. This attack passed off, recurring at the end of a week, and being associated with symptoms of internal hemorrhage. Dr. Briddon saw her early in the evening of October 29th, soon after this attack; diagnosticated rupture of the Fallopian tube with hemorrhage, and advised immediate laparotomy. Drs. Thomas and Walker saw the case in consultation, confirmed the diagnosis, and endorsed the operation. The latter was successfully performed by Dr. Briddon, assisted by Drs. Gerster, Walker, and Sharlau, two hours after the rupture had occurred.

The corpulence of the patient made it necessary to make a long incision, reaching from the umbilicus to

the pubes. Her collapsed condition rendered this almost a bloodless proceeding. When the peritoneum was exposed, a small incision was first made, which gave exit to a large amount of fluid blood. The incision was then enlarged sufficiently to admit the hand, and at least a pint of blood-clot was scooped out as rapidly as possible. The uterus was then drawn up as far as its connections would permit, and the cause of trouble was at once apparent. Part of an ovum, one inch and a quarter in diameter, was found protruding from a rent in the left Fallopian tube close to its uterine extremity. The broad ligament was lifted as much as possible, and a probe, armed with a double stout plaited-silk ligature, was passed through it as low down as could be done, and the ends were firmly secured above the free border. In these manipulations the ovum was forced from its bed in the oviduct, and was removed entire. The hemorrhage appeared to be entirely controlled, the ligatures were cut short, and the toilet was completed by thorough cleansing of the cavity. The wound was then closed by silver wire sutures. No time was lost in completing the dressing, but the patient was removed at once to bed, surrounded with blankets and hot bottles. Her head was enveloped in a warm woollen shawl, a small hypodermic of morphine was administered, and brandy was used subcutaneously. It was not, however, until after midnight that an occasional flicker could be felt in the pulse at the wrist. Vomiting, which occurred, was treated by frequent sips of hot water. Nutrient and stimulant enemata were used all through the night. On the morning of the 30th her appearance was much improved. She was inclined to talk, was even cheerful, and expressed herself as entirely free from pain; she only complained of the vomiting; but, notwithstanding these favorable signs, her pulse could scarcely be felt, much less counted; at times it could not be distinguished at all. The temperature was 101° , the respiration 36. At 10 A.M. her pulse could be counted, and it was 126; after this it improved for twenty-four hours, averaging 130. the temperature for the same period being 101° to 102° . In spite of the most assiduous stimulation, the circulation could not be maintained; she began to sink on the afternoon of the 31st, and died at 9.30 P.M., forty-seven hours after the operation.

The autopsy showed the abdominal wound agglutinated and adjoining omentum adherent. There was no general peritonitis, but the pelvic cavity contained two ounces of odorless fluid. The uterus was enlarged to double its size. At the junction of the left oviduct with the uterus, and encroaching upon the cornu itself, was an ovoid swelling about one inch in diameter, darker than the surrounding structures, of a mottled, violaceous maroon color. Near the junction of the posterior wall of the duct with this swelling was a ragged opening half an inch in length, and leading into a cavity formed mainly out of that portion of the duct that traverses the uterine wall, so that the specimen might be said to represent the variety known as interstitial, or, more correctly, tubo-interstitial gestation. On incising that portion of the cavity that was developed at the expense of the uterine textures, it was found filled with adherent coagulum. The cavity of the uterus was not lined with decidua, and the uterine opening of the oviduct was im-

pervious. Outside the rent were found the ligatures applied during life, and which had effectually controlled the hemorrhage.

It is much to be regretted that the patient died. The lessons to be learned from this case have, however, many practical bearings. It has been proved that a correct diagnosis can be made promptly and under difficulties; that the operation is not in itself attended with any immediate danger to the patient; that the point of rupture may be reached without difficulty, and that the bleeding parts can be effectively secured. In this case it must be recollected that the patient was in collapse at the time of the operation. She would certainly have had a better chance if the laparotomy could have been performed earlier. But obviously this was impossible in view of the necessity of dividing responsibility and of receiving a proper endorsement for an operation which was a novel and hazardous one. The precedent has, however, been established, and we congratulate Dr. Briddon on his correct diagnosis and on his courage and skill in acting up to his convictions as to what should be done in such a desperate case.

MEDICAL OBSERVATIONS CONCERNING ALASKA AND THE ARCTIC OCEAN.

THE report of the cruise of the steamer Corwin to the Northwest Arctic Ocean and the Alaska region, recently issued by the United States Government, affords much valuable and interesting information not only from its rarity, as compared with the receipt of similar reports from other parts of the world, but also from the carefully prepared statistics which it contains relative to the medical condition of that region. For the latter the profession are indebted to the services of Dr. Irving C. Rosse.

Regarding the diseases peculiar to the aboriginal population, in an epidemic which had proven fatal to a large portion of the natives (at Ounalaska), clinical observation showed marked dyspnea, bronchophony, cough, expectoration, pain, insomnia, and *great depression* both physical and psychical. The latter was found to be most characteristic, so much so that in many instances it seemed impossible to impress the patient with the slightest hope, who had made up his mind to die at the onset of the attack. The disease was, moreover, very rapid in its course, but, considering the gravity of the several phenomena, very little of the fever that usually attends pneumonitis was present; the main symptom calling for relief being marked asthenia, for which quinia and stimulants were given with much benefit. In fact the administration of quinine to these natives seemed to be attended with the most magical effects, not only in this but in other affections, an adynamic character of disease being almost invariably exhibited. In the cases in question, however, it is to be regretted that no necropsy was made, as, differing in its type from any of the various forms under which pneumonitis usually presents itself, possibly some distinctive morbid characteristic might have been shown.

Pulmonary phthisis is also not uncommon, and forms a large percentage of the cases of disease, even among the native Indians. Acute rheumatism and acute pulmonary inflammations, however, are not frequently met

with, notwithstanding that these affections might naturally be supposed to prevail in such a climate.

The principal vice which seems to affect these people is an apparently uncontrollable craving for alcoholic drinks; an appetite, moreover, which seems to be a physiological necessity—although the taste is to all appearances an acquired one—there being an “indescribable something” in the Arctic atmosphere that produces what is called the northern craving for drink.

At St. Michael's, the most northern station of the Alaska Company, and almost under the Arctic circle, it appears that no serious epidemics have occurred since 1840, when small-pox was introduced by the Russians. It was found, however, that pulmonary affections and the constitutional effects of syphilis prevailed to an alarming extent. In addition, affections of the alimentary canal are quite common, these being due chiefly to overloading the stomach after a long fast. Here, too, the thirst for rum exercised a dominating influence.

The affections of the eye and its appendages, are quite numerous. Among them several cases of opacity of the lens and of the cornea were noted, and of fatty and pigmental degeneration, together with granular inflammation of the conjunctiva, amblyopia, etc. Total blindness does not appear to prevail to the extent generally supposed, except among the older people (of fifty years and upward), in whom blindness is almost universal. These eye affections are mostly the result of snow-blindness, and are not caused by smoke, as has been erroneously supposed. An impoverished condition of the blood, brought about by bad feeding and the strumous diathesis, probably also bears a predisposing influence. An interesting question, also, in this respect, would seem to be the form of the rods and cones in the retina of the Esquimaux.

Concerning the relation of the Arctic atmosphere to surgery, it is remarked that wounds seem to heal uncommonly well in this region, a fact probably due to the highly ozonized state of the atmosphere and the absence of disease germs and organic dust—a not uninteresting point bearing on the germ theory and antiseptics. This fact is, moreover, noticeable both in man and animals, and even in extensively lacerated wounds, careful approximation of the edges and the application of a retentive bandage is followed by rapid healing unaccompanied by complications. Skin diseases also prevail extensively, which, however, might be anticipated from the condition of the inhabitants, and a few cases of chorea and of cerebro-spinal meningitis are also mentioned.

THE COMMISSIONER OF EDUCATION ON MEDICAL SCHOOLS AND EDUCATION.

THE report of the United States Commissioner of Education for the year 1882 has just appeared, and it contains, as usual, a section devoted to medical education. These sections have heretofore been of much value, but we have to confess that the present one is rather behind the times. The labors of the Illinois Health Board have produced a work which is much later in date, and which shows much more fully, in most respects, the status of our educational system. There are, however, some facts in the present report which will be of interest.

The tables given show that in 1881, there were 96

medical colleges of all kinds, with 12,417 students, and that there were 4,019 graduates at the commencements in that year.

The figures for 1882-3 show that there were in that year 119 medical colleges in the United States, having 11,854 matriculates, and graduating 3,979 doctors of medicine. This shows that despite the increase in the number of colleges, there has been a slight decrease in the number of students and graduates.

Attempts have been made by the Commissioner to show the amount of property owned by the various colleges, and the incomes received by them. The figures given are imperfect, especially as regards the latter point. We observe, however, that there is annually a considerable increase in the amounts representing the value of grounds, buildings, and apparatus. Thus in 1879 the total sum for 68 regular medical colleges was \$1,872,970; for 1880 (72 colleges), \$1,920,170; for 1881 (76 colleges), \$2,208,470.

The Commissioner in his remarks upon medical education correctly states that there is evidence of a steady improvement in the schools, as shown by lengthening of the curriculum, and requirements of preliminary education. There are now 16 colleges in the United States requiring attendance upon three courses of lectures before graduation; while 56 colleges recommend and provide for this without requiring it. There are also 71 colleges which exact some evidence of preliminary education before matriculation. Figures do not show, however, how slight this exaction really is.

THE ADVERTISING RIGHTS OF GENERAL PRACTITIONERS AND SPECIALISTS.

THE venerable and esteemed editor of the *Journal of the American Medical Association* has made some official utterances upon the subject of medical advertising, to which we beg most earnestly to call the attention of our readers. We cannot but think that our Chicago contemporary is doing a serious injury to the profession by advocating for specialists and doctors generally a license, which it never has been and is not now considered decent to assume. We quote his words, referring to medical advertisements:

"No one is prohibited from *publishing* or *using* a professional card *as freely as he likes*, simply announcing himself as doctor of medicine, and giving his residence and office hours. . . . If he desires to limit his practice to the treatment of any particular diseases, he can say on his card that 'his practice is limited' to this or that class of diseases."

We regret keenly that statements like the above should go out stamped with the approval of the "highest exponent of the Code of Medical Ethics."

To say that any physician "can publish his professional card as freely as he likes," is to take down all the barriers at once against promiscuous medical advertisement. With such a liberty one could take up half a column in a daily paper and still keep within the pale of the Code. In the large cities of the East, and in most, if not all, of those in the West, reputable physicians do not put their card and office hours in the daily papers, as do the quacks and abortionists. If it, under the

sanction of the American Medical Association, became the custom to advertise in this way, we hardly know where the end would be. In small towns it is perhaps well enough to allow the local physicians to insert their cards along with the dentists, carpenters, and tinware men. But in cities where there are daily papers this practice furnishes too great opportunities for abuse. It is wisely looked down upon by those whom we most esteem, and we trust that it will continue to be.

The permission to announce the "practice limited to" will strike sensible people as being silly, if not actually dangerous. Where shall we find the censors to say that a practice is really limited as announced? And how many who read the sign will find therein any different meaning from that of "specialty." To those who know the wiles of human nature, the opportunities here for abuse are most apparent; while the attempt to make a distinction between "practice limited" and "practice special" appears to us to be a foolish quibble.

If we are to take the position that medical men should not advertise, let us maintain it in its integrity.

MEDICINE IN ALLEGHANY COUNTY.

WE have published editorially the statements on both sides of the question as to the ethical condition of the Alleghany County Medical Society, and as the subject has not a wide interest, we will dismiss it now and finally with but brief comments. We have perfectly satisfactory evidence of the good standing and good faith of our first correspondent, while that of our second is well known.

It is evident from facts admitted by both parties, that the Alleghany County Medical Society is a reputable organization, but that it has a few very weak members who, if not actual charlatans, are dangerously near the line. As to its prosperity, we are authoritatively informed that since 1870 it has increased in size from 100 to 116 members, and that there are in Alleghany County 1,268 registered practitioners; in Pittsburg alone, 376.

We are forced to believe that some Pittsburg physicians consider it proper to announce their names, and even their specialty, by advertisements in the daily press, and we believe it is true that a number of Pittsburg physicians designate their specialty upon their office signs. Such practices are certainly derogatory to professional dignity, and ought not to be countenanced.

While some bad practices thus undoubtedly exist, we do not wish to say that the Pittsburg physicians are not fully the equal of those of other cities in professional skill and character. Only it is unfortunate that they should allow their general standing to be injured by the practices of a few.

THE STRUGGLES OF A YOUNG DOCTOR.

WE have received a letter from a young physician residing in a large interior town, and publish the substance of it elsewhere. His complaint is that the older physicians underbid the younger ones, making visits for fifty cents and furnishing the medicine. These older offenders also trust patients, and continue to treat them, although unpaid accounts have been standing for years. We infer that there are mutual recriminations between the younger and older parties. Our correspondent says that he has

spent eight years in studying medicine—six in college, two in a hospital—yet now, with a fair number of patients, he can “barely scrape along, because if I dun I lose my patients.”

Although there may be much justice in our correspondent's complaints, we cannot altogether commend the spirit which his letter shows. The circumstances described are the inevitable result of a crowded profession and weak human nature. But neither these nor any other circumstances justify younger men from abusing the old, because the latter do not act fairly.

Our correspondent does not think that there are too many doctors in his town, but that all could live comfortably if patients would pay decently, and if the older doctors had more self-respect. But behind these incidental causes we can see the working of the law of supply and demand; and the demand is for the patients, not the doctors.

At the same time, it is truly disgraceful and unjust to the profession that members should sell their services for sums less than a good corn-doctor receives.

Let the younger men and the respectable older ones attack this abuse in a manly spirit. They will then obtain sympathy certainly, and perhaps success.

THE REPORT OF THE FRENCH CHOLERA MISSION.

At a meeting of the Société de Biologie, Dr. Straus, of the French Cholera Mission to Egypt, gave some account of the work done by the mission. We have already referred to this briefly. It was found that the rice-like stools consisted of epithelial debris, and that these epithelial cells had undergone the process known as *nécrose de coagulation*.

Micro-organisms were found in vast numbers and variety in the intestines. Among them were bacteria termo and bacilli, some resembling those of tuberculosis, but smaller, others resembling the bacilli of glanders, being the same as were described by Koch. But Dr. Straus did not think these could be the bacilli of cholera, because their presence was not constant, and because they were found in other places than the intestine.

There were discovered also in the blood elongated corpuscles, recalling to mind those of the *rouget*, but much smaller. Attempts to color and cultivate these failed. Attempts to inoculate lower animals with the discharges also failed. In fine, the French Cholera Mission accomplished nothing except to furnish some evidence against the findings of Koch, and to show by the death of one of the members that copper does not prevent cholera.

M. Paul Bert offered to Dr. Straus the consolation that he had at least succeeded in pointing out the error of Koch.

This is no doubt a comfort to the Gallic mind, but unfortunately the scientific world just now feels much more confidence in German than in French methods of mycological investigation.

THE STATE OF OHIO has no Board of Health. It is proposed, therefore, to organize a State Sanitary Society and a movement to this effect has begun.

News of the Week.

A NEW MEDICAL SOCIETY IN NEW YORK has been organized and called The New York Society for Medico-Scientific Investigation. The objects of the Society are, first, the introduction and proving of new drugs; second, the re-proving of drugs of which the pathogenesis is incomplete or inaccurate; third, the collection of data bearing upon disease in general, which would include the investigation of epidemics, their causes, the conditions present, such as atmospheric and climatic, the relation of drugs thereto, the so-called season remedy, the limit of drug attenuation, etc.

THE EXISTENCE OF A MICROCOCCUS OF PNEUMONIA has been confirmed by Professor Carl Friedländer, of Berlin, who has cultivated these organisms and produced croupous pneumonia by inoculating them in dogs and mice.

THE QUEEN'S LOCOMOTION.—It is gratifying to learn from the English medical journals that “the Queen's power of locomotion is considerably ameliorated.” It would be interesting to know how she walks with her locomotive powers thus ameliorated, and perhaps some successive instantaneous views might be of interest to her loyal subjects, who appear to be more loyal than grammatical.

DR. J. MARION SIMS is said to have left, ready for publication, a story of Revolutionary times, entitled, “Lydia McKay and Colonel Tarleton.”

THE SANITARY CONVENTION AT BALTIMORE, held on November 27th and 28th, was a very successful meeting. Papers were read by Dr. J. F. McShane, on “Vital Statistics”; by Colonel G. E. Waring and Mr. C. H. Latrobe, on “Sewage”; by Dr. W. S. Forwood, on “Canning Fever”; by Dr. John Morris, on “The Etiology of Baltimore Catarrh”; by Dr. W. S. Wyman, on “Quarantine”; by Dr. E. J. Henkle, on “The Last Small-pox Epidemic in Baltimore”; and by Dr. R. Gundry, on “The Conflict of State Power and Individual Rights in Sanitary Matters.”

“GOOD ON FITS.”—A contributor to our esteemed contemporary the *Mississippi Valley Medical Monthly*, reports that he has treated 765 cases of “fits” and has cured seventy-five per cent. of them. He ought to come East and teach his less fortunate brethren the secret of his skill. We suspect, however, that he has adopted the old plan of throwing all his doubtful cases into fits and then treating them.

TESTING THE CONSTITUTIONALITY OF MEDICAL REGISTRATION LAWS.—A graduate of the Louisville Medical College in the year 1873 recently presented his diploma before the State Medical Examining Board of Minnesota, and demanded a license. This he was refused on account of unprofessional conduct. He has now brought a suit to test the constitutionality of the law.

THE BACILLUS OF YELLOW FEVER has been found, according to Dr. Domingos Freire, Commissioner of the Brazilian Government. It is a cryptococcus and has

been appropriately christened with the name of *c. xanthogenicus*. Dr. Freire states that he has cultivated the organism and has, by a different method from that of Pasteur, obtained what he thinks may be a protective vaccine. His method is founded on the principle of "anti-microbism," that is, the cultivation of organisms antagonistic to those of yellow fever. Some guinea-pigs have been successfully protected by his virus. But it is a long way from the guinea-pig to man.

PROFESSOR LEUBE has been called to Zurich to take the chair of the late Professor Huguénin.

TEMPERANCE AND MUSCULAR EXERTION.—The pedestrian Weston has started out from London on a walking and lecturing tour. He intends to walk fifty miles a day for twenty days, lecturing at the same time upon temperance, and drinking only water. It is difficult to see what this ingenious advertising scheme will prove.

THE RUSSIAN PHYSICIAN, DR. ECK, sent to Egypt to investigate the cholera, says that it was undoubtedly imported from India.

A DEFAMER OF THE PROFESSION.—The *British Medical Journal* and the *Medical Press and Circular* unite in severely blaming Dr. H. Donkin, a physician who wrote an anonymous letter to a London daily paper criticizing Drs. Ringer and Murrell for having, as he said, experimentally used nitrite of sodium in dangerous doses. "Never do we remember," says the *Press and Circular*, "an instance in which cowardly resort to anonymous publication has been resorted to by any one of position in the world of medicine," as was done by Dr. Donkin. This is the person who was so quick to publish in the *Times* a denunciation of the late Dr. Beard for his experiments in hypnotism before the British Medical Association some time ago.

THE NEW YORK STATE BOARD OF HEALTH reports as a result of its investigation into the cause of malaria along the Hudson, that this disease has been brought about, in part at least, by the railroads making embankments which prevent free drainage into the river.

THE POST-GRADUATE MEDICAL SCHOOL has been obliged to enlarge its quarters, and has taken another floor in the building which it occupies. The School has had a very prosperous opening, and begins its second term with about sixty students, all of whom are graduates in medicine.

THE NEW YORK POLYCLINIC has at the present date seventy students in its various classes. These are also all graduates. Certainly post-graduate instruction is becoming popular.

THE CASES OF TYPHOID FEVER AT YALE COLLEGE are said to have been mostly imported. Local physicians say, however, that some of the fevers are due to drinking water from the wells on the campus, these being near drains.

ENLARGEMENT OF ST. VINCENT'S HOSPITAL.—A new wing to the St. Vincent's Hospital, containing thirty-four rooms, besides open wards, was opened this week. The cost has amounted to \$150,000. It is intended for pay patients.

A NEW MEDICAL COLLEGE AT WINNIPEG was recently organized, under the name of the Manitoba Medical College.

DR. DUDLEY S. REYNOLDS has resigned the editorship of the *Medical Herald*.

THE GERMAN CHOLERA MISSION has gone to Calcutta, instead of Bombay as at first intended. Better facilities are to be found at the former place. The Mission has been cordially received by the English authorities.

THE LATE DR. J. MARION SIMS.—At a called meeting of the Faculty of the Baltimore Medical College, held on November 27th ultimo, the following preamble and resolutions were offered by Professor Harvey L. Byrd, and adopted unanimously, viz.:

Whereas, We have learned with profound sorrow and deep regret of the death of Dr. James Marion Sims, which sad event occurred in the city of New York on November 13, 1883; and

Whereas, It behooves us as a corporation and as individuals, to bear testimony to his brilliant career and great achievements, which have enriched the profession of medicine so much, especially in the knowledge and skill he applied so successfully for the relief of suffering woman-kind; be it therefore

Resolved, That we deplore the decree of our Heavenly Father which called from the midst of the living James Marion Sims, and from the profession he so much honored, and thus stilled forever the cunning hand that had wrought relief to so many suffering women in both hemispheres.

Resolved, That these proceedings be spread upon the minutes of this meeting, and that a blank page of the records of this corporation be inscribed with his name and the dates of his birth and death; and that a copy of the foregoing be forwarded to his bereaved family with the assurance of our sincere sympathy and condolence in this their irreparable loss.

Resolved, That the editors of THE MEDICAL RECORD and *Medical Times* be respectfully requested to publish the same.

A MEDICO-LEGAL SOCIETY has been organized in Philadelphia. Professor John J. Reese delivered an address before it at its opening session.

ADULTERATION OF MILK IN LONDON has, according to G. W. Wigner, F.C.S., been reduced to a science. Of three hundred samples obtained in one day from different districts only three per cent. showed no adulteration. The average of all the milk showed nineteen per cent. of added water, and it is estimated that milkmen get \$1,330,000 annually by selling water.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.—The next meeting of this Society will be held Friday evening, December 21, 1883, instead of Christmas eve.

ORGANIZATION AND CO-OPERATIVE WORK AMONG STATE BOARD OF HEALTH OFFICERS.—At the last meeting of the American Public Health Association, it was determined to form some kind of organization among State Board of Health officers, for the discussion of matters belonging to their official work. A committee was appointed and it has been arranged to have a meeting

and organize, at Washington, D. C., in May next, during the meeting of the American Medical Association. The scheme thus proposed seems likely to be a most useful one.

A SUCCESSFUL CASE OF NEPHRECTOMY by the peritoneal method was recently performed by Mr. Richard Davy, of London. The patient, a man, aged fifty-three, had a large fibro-cystic left kidney.

THE NEW JERSEY SANITARY ASSOCIATION held a meeting in Trenton, December 7th. The subject of school hygiene was especially discussed.

SENSITIVE DRUG STUDENTS.—The students of the National College of Pharmacy at Washington, D. C., deserted their school because a colored student was admitted. Harmony was restored by the Faculty promising to admit no more of the offending race.

DRS. A. A. MACDONALD AND H. E. HUGHES, who were accused of falsely certifying that one Mr. Haas was insane, and of thus securing his confinement in an asylum, have been relieved of the charge. The well-known excellent standing of these gentlemen make the charge against them on the face of it absurd and unjust.

THE MONEY-VALUE OF AN ARM.—It may be of some interest to surgeons to learn that the money-value of an arm, lost in the Taunton Locomotive Works by Mr. E. H. Rankin, was, in the opinion of a jury, \$9,000.

NEW YORK ACADEMY OF MEDICINE—NOMINATIONS FOR OFFICERS.—The following candidates were placed in nomination at the stated meeting, December 6th, to be voted on at the first stated meeting in January, 1884: For *Vice-President*, Drs. Robert F. Weir, and Henry D. Noyes; for *Trustee*, Drs. Cornelius R. Agnew and Samuel S. Purple; for *Treasurer of the Board of Trustees*, Drs. Frederick A. Castle and John H. Hinton (to fill vacancy); for *Committee on Admissions*, Drs. Daniel Lewis and Edward H. Janes; for *Committee on Education*, Drs. W. Gill Wylie and John Shrady; for *Committee on Ethics*, Drs. C. Dixon Varley and Francis V. White; for *Committee on Library*, Drs. Abraham Jacobi and Henry D. Nicoll; for *Treasurer of the Academy*, Drs. William F. Cushman and Edward H. Peaslee.

PAPERS FOR THE ANNUAL MEETING OF THE STATE MEDICAL SOCIETY.—Dr. Hutchins has again sent out a notice requesting members and delegates to furnish papers for the meeting of the State Medical Society, in February next. We trust that his energetic efforts to secure a successful meeting will find a hearty response. We especially urge the general practitioners throughout the State to send in records of their experience. We do not think there is any doubt that plenty of papers will be forthcoming. It is the practice of medical men to put off writing as long as possible, and Dr. Hutchins's method of working for papers so long in advance is a good one.

MEDICO-CHIRURGICAL SOCIETY OF GERMAN PHYSICIANS OF THE CITY OF NEW YORK.—The following gentlemen have been elected officers of this Society for the ensuing year: *President*, Dr. Felix Nordemann; *Vice-President*, Dr. Otto Heubner; *Secretary*, Dr. George W. Rachel; *Corresponding Secretary*, Dr. C. A. Von Ramdohr.

Reviews and Notices.

MANUAL OF GENERAL MEDICINAL TECHNOLOGY, including Prescription Writing. By EDWARD CURTIS, A.M., M.D., Professor of Materia Medica and Therapeutics, College of Physicians and Surgeons, Medical Department of Columbia College, in the City of New York. New York: William Wood & Co. 1883.

THIS is one of Wood's series of pocket manuals written by a competent and painstaking teacher in this department of medicine. The lecture style has been retained, and the technicalities of prescription writing have received especial attention. The book is divided into two parts: first, the technology of medicines; second, the technology of medicating. In the first are chapters containing a concise synopsis, together with brief comments, on the naming, the forms, determining the quantities, and prescribing medicines. In the last, the conveniences of the metric system are pointed out, and a comparison made between it and the old system by writing the same prescription according to both methods.

The reviewer notices the following, which seem to be errors. On page 158 the word "tablespoonful" appears for "teaspoonful," and the reverse is seen on page 165, where the word "teaspoonful" is used for "tablespoonful." Again, the approximate metric equivalent for $\frac{1}{2}$ j. given in the author's table is 30.00 gms., while the approximate metric equivalent given in the example for $\frac{1}{2}$ jss. is 35.00 gms., and for $\frac{1}{2}$ ss. 20.00 gms. If these are not errors they will do to other readers just what they have done to the reviewer, give rise to an uncomfortable degree of confusion.

The reader will also notice that the author calculates on the basis of six teaspoonfuls for a fluidounce, and three tablespoonfuls for two fluid ounces. This is worthy of note because it varies considerably from the average quantities heretofore regarded as equivalents.

The book will interest those who wish exact instruction in prescription writing, according to the methods now in use.

EPITOME OF SKIN DISEASES, WITH FORMULÆ FOR STUDENTS AND PRACTITIONERS. By the late TILBURY FOX, M.D., F.R.C.P., and by T. COLCOTT FOX, M.B., M.R.C.P. Third American edition, revised, and with additions by T. Colcott Fox, B.A. (Cantab.), M.B. (Lond.), Physician for Diseases of the Skin to the Westminster Hospital, etc., etc. Philadelphia: Henry C. Lea's Son & Co. 1883.

AFTER the many crude and unscholarly volumes, yclept manuals, with which medical literature teems at present (and which are usually the abortive deliverances of ambitious gentlemen with an unfortunate aptitude for compilation, and which owe whatever popularity they may attain to the specious allurements they offer of a royal road to a lucrative specialty), it is a relief to turn to this little book, which one can distinctly and cordially recommend. It is an admirable condensation of the classical views of Tilbury Fox, developed and elaborated to conform to the more modern ideas of British dermatology. The classification of dermal diseases endorsed by the American Dermatological Association is inserted, a practice which more of our foreign authors would do well to imitate.

THE PATHOLOGY AND TREATMENT OF VENEREAL DISEASES. By FREEMAN J. BUMSTEAD, M.D., LL.D., and ROBERT W. TAYLOR, A.M., M.D. Fifth edition, revised and rewritten, with many additions, by Dr. Taylor. 8vo, pp. 906. Philadelphia: Henry C. Lea's Son & Co. 1883.

It is known to many that for some months before his death the health of Dr. Bumstead was so bad that almost the whole of the labor of preparing the fourth edition of this work for the press devolved upon Dr. Taylor, the

junior member of the firm of authors. That the work was well done is evident from the fact that but four years have elapsed since its appearance, and a fifth edition has already been called for and published.

In the new edition Dr. Taylor has made but few changes in the text, the principal alteration being the substitution of the first personal pronoun for his own name. He has, however, made many additions to it, about seventy pages in all being devoted to them. A mere enumeration of the more important of these will furnish an opportunity of judging how well he has succeeded in keeping the book up to the high position it had attained in the estimation of the medical profession under its original editor. The great merits of the earlier editions were so generally recognized that it would surely be a work of supererogation to point them out here.

Among the additional subjects discussed are: some additional means by which syphilis may be communicated, the possibility of inoculating animals with the disease (to this more than five pages are given), the theory of its nature advocated by Dr. Otis (which the author mentions but to condemn), excision of chancre, chancre of the cervix uteri, the influence of syphilis on the healing of wounds, the use of salicylic acid in palmar syphilides, of chromic acid in lingual affections, a modification of Schede's method of treating wounds as applied to ulcerating gummata, the use of local mercurial fumigations (illustrated by a new plate), congenital syphilis of the throat, the use of coca, the treatment of syphilis by the "chromwasser," so strongly advocated by Güntz, and even the decoction of various herbs recently praised by the late Dr. Marion Sims. Another important addition to the work consists of a chapter devoted to syphilis and marriage.

A careful perusal of all this new matter will undoubtedly convince the reader that in choosing Dr. Taylor as his literary heir and successor, Dr. Bumstead took the best possible step to render it certain that at least one good thing that he did should live after him, and it also warrants the belief that future editions of the work will be worthy of their predecessors. The present edition well sustains the enviable reputation that Dr. Taylor had already earned for himself as an original worker and thinker, a careful observer, a man of positive views, and as the author of a large number of valuable contributions to our knowledge of syphilis and kindred diseases.

Thirteen chromo-lithographic pictures have been added to the present edition. These will prove of great assistance to those who desire to become familiar with the appearances of such lesions, but who lack opportunity of observing them in the living subject.

Regarding the work as a whole it is confidently asserted that no physician or student who wishes to learn how to recognize, or to properly treat, the different venereal diseases, or to have an authority at hand containing the latest and best views on these affections, can afford to neglect to read and keep the latest edition of Bumstead and Taylor.

AN ETHICAL SYMPOSIUM; being a Series of Papers concerning Medical Ethics and Etiquette from the Liberal Standpoint. By A. C. POST, W. S. ELY, S. O. VANDER POEL, L. S. PILCHER, T. HUN, W. C. WEY, J. ORDRONAU, D. B. ST. J. ROOSA, C. R. AGNEW, A. JACOB, and H. R. HOPKINS. New York: G. P. Putnam's Sons. 1883.

This little volume is a campaign document, just as Dr. Flint's manual was part and parcel of a great medical canvass. Now that the active contest is as good as over, having resulted in victory for the New Code party, it will not be necessary to do more than glance at the contents of this ethical symposium. It embodies the best arguments clothed in plain English that the advocates of liberalism can advance. And it must be said that they appear in the shape of a formidable phalanx of common

sense, honesty of conviction, and fearless prediction of remote consequences. Gauged by the standard of these liberal essays, the Old Code has certainly outlived its period of usefulness, and it was well that it was thrown overboard as useless ballast. The progress of that noble vessel, called medicine, should now be all the quicker.

A HAND BOOK OF THERAPEUTICS. By SIDNEY RINGER, M.D., Professor of the Principles and Practice of Medicine in University College. Tenth Edition. New York: W. Wood & Co. 1883.

It is only necessary to chronicle the appearance of a new edition of this well-known hand-book. All other comment is superfluous. The general plan and arrangement of the volume remain unaltered. A concise account of new and important discoveries made in pharmacology and therapeutics since the appearance of the last edition has been incorporated with this the last issue. Ringer's therapeutics will be read with advantage by students, and will be occasionally referred to with benefit by the practitioner.

THE AIMS OF THERAPEUTICS.—At the recent Congress of German Naturalists and Physicians Professor Liebermeister delivered an address upon the aims of modern therapeutics (*London Lancet*). He said that owing to the "epoch-making" discoveries upon the nature of disease which have been made within the last decade, great changes were taking place in treatment which had by no means yet attained their full development. Although theoretically therapeutics is based upon pathology, advances in pathology had not always been followed by a similar advance in therapeutics, and he instanced the fact of the marked transition from the old symptomatological system of medicine to that based upon pathological anatomy which occurred early in the century, as leading to no corresponding change in methods of treatment. But as anatomical study increased and physical diagnosis improved a period of skepticism with regard to the influence of remedies and expectant treatment came into vogue. Regarded by some as a retrogression this was really a great advance in therapeutics. It was not only the liberation from the dogmatism of the schools and systems, but the opening up of a scientific study of the object. Then it came about that the anatomical standpoint yielded to the etiological the recognition of the important part played by micro-organisms in many diseases being the cause of this change. The doctrine of *contagium vivum*, strenuously disputed twenty years ago, has practically become generally accepted, and prophylaxis is now the first aim in dealing with disease. He pointed out how the pathogenetic organisms may be considered in two great classes—those, namely, which prevail everywhere, and those which require special conditions for their occurrence. In this way he contrasted the poison of pyæmia, septicæmia, osteomyelitis, etc., on the one hand, with those of malaria, cholera, typhus, scarlet fever, and other endemic and epidemic diseases on the other. Measures of prophylaxis were identical with general sanitation and public and personal hygiene. He strongly insisted upon quarantine as protective against the spread of epidemics, and rebuked England for allowing, in the face of the cholera, its mercantile interests to render it blind to the interest of the public welfare of the whole of Europe. When the infective germs have gained entrance into the body, then specific treatment is called for, as quinine in malaria, calomel in typhoid fever, salicylate of soda in rheumatism. Further, there are measures for direct prophylaxis, as in curing a susceptibility to catarrhs, which afford so favorable a soil for the tubercle bacillus. Other methods are symptomatic and alterative; and although therapeutics is still largely empirical, the path along which it must advance has been much cleared by the advance of general medical knowledge, so that there was much to hope for in the future.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, November 14, 1883.

GEORGE F. SHRADY, M.D., PRESIDENT, IN THE CHAIR.

(Continued from page 635.)

HYPERTROPHY OF THE HEART—CORS BOVINIS—WEIGHT FIFTY-THREE OUNCES—VENESECTION, BLISTERS, AND THE ACTUAL CAUTERY USED WITH BENEFIT FOR THE RELIEF OF SYMPTOMS.

DR. BEVERLEY ROBINSON presented a heart removed from the body of a man thirty-nine years of age, whose stature was very much above the average. His family history was negative. He had been a free drinker of malt liquor and spirits and gave a doubtful history of chancre, occurring seven or eight years ago. He came to St. Luke's Hospital suffering from the ordinary symptoms of chronic valvular disease of the heart, such as dyspnoea, etc., and there was well-marked anasarca. He was treated with all the ordinary cardiac stimulants, but without special benefit. A blister was applied over the precordium and it relieved the dyspnoea very notably. The Paquelin cautery also was applied over the precordium at sixty or seventy points, with the result of giving marked temporary relief from the dyspnoea. At one time eighty ounces of fluid were taken from the right pleural cavity, and forty ounces subsequently. Finally, the jugular vein in the right side being much distended and tense, the patient was bled and *fourteen* ounces taken, and again he was markedly relieved. There was some evidence of pericardial effusion, and a hypodermic needle was introduced, but only half a syringeful of pure blood was obtained.

The case was especially interesting on account of the size of the heart, the temporary relief afforded by venesection, and the absence of serious results following the puncture of the pericardium, although the needle entered the heart-wall.

The following notes of the autopsy were furnished by Dr. F. Ferguson:

The body is fairly nourished; rigor mortis is well marked and there is general anasarca. The peritoneum contains eight ounces of clear serum. The diaphragm on the right side is at the fourth interspace on the left side at the fifth rib. Thorax: There are old loose adhesions binding the right lung to the chest-wall at different points over its entire surface. There are nine ounces of fluid in the right pleural cavity. There are no adhesions or fluid in the left pleural cavity. The pericardium contains three ounces of pus and serum. Heart: The heart is enormously increased in size, it weighs with the pericardium attached three pounds and five ounces. Both the parietal and visceral layers of the pericardium are intensely congested. There are several areas of thickened pericardium on the surface of the heart and there are circumscribed areas of thickening in the walls of the coronary arteries. From the upper portion of the right auricle to the apex of the heart it measures twenty centimetres; and from the attachment of the segments of the aortic valve to the apex it measures fourteen centimetres. The ventricular walls, especially the left, are much hypertrophied. The thickness of the left ventricular wall varies from one to three centimetres, its greatest thickness is at the base of the heart. The ventricles are enormously dilated and distended with recently clotted blood. The mitral valve admits three fingers, and its segments are thicker than normal. There is fusion of two of the cusps of the aortic valve and a rupture between them which admits a cylinder one and a half centimetres in diameter. The edges of this opening are jagged and covered by shreds of fibrin. The cusps of the aortic valve are much thickened. There are extensive areas of endarteritis and patches of atheroma in

the aortic wall. Valves in the right side of the heart are normal. The lungs are intensely congested and oedematous. The spleen is normal in size, firm in structure, and deeply pigmented. The kidneys are firm in structure, surfaces slightly granular and lobulated. Markings are wanting, and there is fat in the tubules of both the cortex and pyramids. The stomach is intensely congested, and its mucous membrane is thickened slightly. The mucous membrane of the intestines is congested. The liver is small, stained with bile-pigment, throughout contains much connective tissue and some fat.

Microscopic examination.—The muscular fibre of the heart contains much fat, the transverse striæ are not generally visible. The vessels of the lungs are everywhere distended with blood, and the epithelium lining the air-vesicles is pigmented. The kidneys contain an excess of connective tissue, there is much fat in both the convoluted and straight tubules. There are also granular casts in some of the straight tubules and in some of the tubules of the cortex. The vessels are everywhere distended with blood. The liver contains much fat, in places arranged around the periphery of the lobules, but sometimes around the central vessels. It is stained with bile-pigment. The fibrous tissue is everywhere increased. There are areas of atrophy of hepatic cells around the central vessels and in the intralobular regions.

THE PRESIDENT referred to the fact that Dr. Alonzo Clark had presented to the society a heart that weighed fifty-seven ounces.

DR. ROBINSON also presented specimens which illustrated

THE INTESTINAL LESIONS OF TYPHOID FEVER.

They were removed from the body of John G—, twenty-three years of age, a native of Scotland, and a plasterer by occupation, who entered St. Luke's Hospital October 3, 1883. The notes of the history were furnished by Dr. Samuel T. King, acting senior assistant physician. The patient was admitted suffering apparently from a relapse of the fever which began six weeks previously. There was notable tympanites, marked adynamia, and elevated temperature. On October 3d the temperature was 104° F.; on the 4th, 101° F.; on the 5th, 103° F.; on the 7th, 98½° F.; and on the 8th, 101.5° F. On the evening of the 8th the temperature began to fall, and on the morning of the 10th it was 96.6° F., and during that time there was active delirium, which continued until death, which took place October 14, 1883.

The following is Dr. F. Ferguson's report of the autopsy: The alveolar walls of the lungs are thickened, the vessels are filled with blood, and the epithelium lining the alveoli and loose in their interior contain pigment granules. The epithelium lining the urinary tubules is excessively granular, but there are no casts nor increase in the fibrous tissue of the kidneys. There is pigment in the liver-cells surrounding the central vessels, the organ otherwise is normal. There are numerous irregular ulcers in the intestines with elevated edges and many of them with smooth bottoms. No tubercles were found associated with these ulcers, and microscopically they are surrounded by a zone of hyperæmia, and their edges and bottoms are composed of smooth muscular fibres and numerous small round cells.

There are no giant cells nor the bacilli of tubercle.

Remarks.—At the autopsy it was found that there were two distinct perforations of the small intestine, due to typhoid ulcerations. One of these, which seemed to be of somewhat older date, opened directly into the peritoneal cavity; the other, more recent, opened into a purulent cavity which was shut in, in part by intestinal convolutions, in part by false membranes which united these convolutions together. A moderate amount of purulent fluid was found in the peritoneal cavity, but it was doubtful whether or not this effusion took place before death, or was occasioned by rupture of the wall of the abscess during the autopsy, and at the time when the

contents of the abdominal cavity were examined. It will be noticed that on the evening of October 8th, the temperature fell rapidly from 101.4° until the morning of October 10th, when it marked only 90.6° .

During life it was not determined what the sudden and great fall of temperature could fairly be attributed to. The patient had excessive tympanites and had become delirious, and remained so until his death. In view of the fact that the patient was suffering probably from a relapse of typhoid fever, that a pneumonia of the left apex had shown itself a few days before, and that subcrepitan râles were found all over the lungs posteriorly, a condition of acute phthisis was strongly suspected. It now would appear, inasmuch as the lungs and other organs contained no tubercles, that the patient's temperature curve and general bad condition before death was brought about by the purulent formation in and around a portion of the intestine, as well as by the perforations themselves.

PERICARDITIS—CARDIAC HYPERTROPHY—CHRONIC DIFFUSE NEPHRITIS.

DR. F. FERGUSON presented specimens illustrating the above lesions, removed from the body of a man, aged twenty-five, single, a native of the United States, and a cigar-maker by occupation, who was admitted into New York Hospital on March 25, 1883.

There was no rheumatism or nephritis in his family, but he had himself suffered from rheumatism two years before his admission into the hospital. He was for a long time a steady drinker of beer and whiskey, but considered himself quite well, although not of robust physique, up to three months before his admission into the hospital, when he began to suffer from frontal headaches, dyspnoea, oedema of the feet and ankles, and cardiac palpitation on exertion. He also complained of disturbance of vision, slight pain in the lumbar region, nausea and vomiting.

On admission he was well nourished, there was no oedema, the post-cervical and inguinal glands were slightly enlarged. His heart was normal in position, there was a loud systolic bruit heard at the left nipple and over the base on both sides of the sternum, also in the left infra-spinous fossa. Respiration was intense, and blowing in character, and there were coarse râles heard over both lungs. His temperature was 99° , respiration 30, and his pulse 100 per minute.

He was given diuretics and appropriate diet, and his headaches disappeared and his condition in every respect improved markedly until April 16th, when his headache returned; he complained of anorexia, and suffered from a general sense of depression. At this time, as ever since his admission, he passed from fifty to sixty ounces of urine every twenty-four hours. Urine contained considerable albumen, small amount of blood and pus, also hyaline and granular casts.

On April 23d, and up to May 1st, he complained of a sense of oppression over the front of the chest, dyspnoea, and at times orthopnoea. At this time he was passing less urine, thirty-five to forty-two ounces a day, with a specific gravity of 1.014, and presenting the same chemical and microscopical character noted above. Examination of the heart at this time did not indicate any lesion of the pericardium. His symptoms continued—headache, dyspnoea, pericardial pain, and a sense of oppression over the anterior part of the chest.

On May 6th physical examination revealed an area of flatness one and one-half inch to the left of the apex beat, which was in its normal location. The area of flatness continued to increase, and on May 15th systolic roughening was appreciable over the entire precordial area. On the 18th there was a distinct pericardial friction murmur with the maximum of intensity at the apex. All the above symptoms were constantly becoming more aggravated; physical examination from time to time detected the presence and increase of fluid in both pleural cavities. His respiration was irregular, super-

ficial, and labored. He suffered much from nausea and vomiting. The quantity of urine diminished to twelve ounces in twenty-four hours. During the night of May 26th he was delirious, his heart-action was very feeble, sixty to eighty beats per minute, his respiration eighteen to twenty-eight per minute, and temperature not at any time higher than 99° . He died on the following day.*

At the autopsy the body was found emaciated. The peritoneum was normal. The pericardium contained 60 c.c. of bloody serum. Both layers of the pericardium were covered by recent fibrin, and the pericardium beneath the exudata was intensely congested and hemorrhagic in places. The left ventricular wall is much hypertrophied and the ventricle considerably dilated; the valves are competent. The sarcois elements of the cardiac cells are largely degenerated into fat. The lungs presented the condition of brown induration. The kidneys were firm, surfaces slightly granular; markings were obscure. They contain excess of connective tissue, and the epithelium of the tubules was very generally converted into fat. The mucous membrane of the stomach was intensely congested. The mucous membrane of the intestines was also congested. The liver was small; there was increase in its fibrous tissue; it was throughout deeply pigmented.

DR. HENRY J. GARRIGUES presented specimens illustrating

DISSECTING METRITIS.

In the last year I presented specimens from four cases of dissecting metritis (MEDICAL RECORD, vol. xxii., p. 413, and vol. xxiii., p. 215). Later I described the disease more at length in an article in the *Archives of Medicine* (April, 1883), adding two new cases. I present here the specimens from these two cases, besides two others from cases not yet published, which form my seventh and eighth cases.

CASE VII.—Jane K—, aged twenty-eight, Irish, tripara, was delivered in Maternity Hospital on March 3, 1883. The head was extracted by means of the forceps in left occipito-posterior position of the vertex.

The following days there was a somewhat increased temperature (101° to 102.5°). The lochia at the same time being fetid, an intra-uterine injection of two per cent. carbolyzed water was given, besides vaginal injections, quinine, and salicylate of soda.

On the fifth day (March 8th) the fundus was yet only one and a half inch below the umbilicus, and a little tender. Tenderness was likewise found on deep pressure in the right iliac fossa. She had no pain, and the temperature was normal. She was very anæmic and had a poor appetite. The lochia were fetid. At the posterior commissure and involving a slight laceration of the peritoneum were found several diphtheritic ulcers. The vagina was clean, but of a dull reddish color. On the anterior lip of the cervix was seen a small, suspicious spot. All these spots were cauterized with a fifty per cent. solution of chloride of zinc, and the uterus washed out with two per cent. carbolyzed water.

The next day (March, 9th) the patient was delirious. The uterus was washed out with a concentrated solution of boracic acid. An ice-bag was applied over the uterus and groin, and the patient was given ergot, quinine, and brandy.

The condition remained about the same until the nineteenth day after confinement when a body was seen protruding through the vulva. By means of a speculum it was seen to pass through the cervical canal, whence it was easily removed with a pair of dressing-forceps. It was oval and measured seven centimetres in length by two in width. Like similar specimens it showed many sinuses with thrombi, and microscopical examination revealed that it was composed of smooth muscular fibres interspersed with inflammatory elements. The highest temperature reached 102.5° F. (March, 7th). Mostly it was normal in the morning, with a slight rise in the

evening. The pulse varied between 80 and 102. After the expulsion of the muscular mass the patient made a rapid and complete recovery.

CASE VIII.—Bessie R—, aged twenty-three, Russian, primipara, was delivered in Maternity Hospital on September 15, 1883. Normal labor. Slight rupture of the perineum which was touched with tincture of iodine. The next day the fundus was somewhat tender, the lochial discharge not very free and somewhat fetid. On the vaginal wall was seen a diphtheritic ulceration extending from the perineum one inch backward, which was dressed with Peru balsam and iodoform four times a day. The vagina was syringed as often with one and a half per cent carbolyzed water.

The next day (September 17th) she complained of great pain in the abdomen. The lochia were profuse and fetid, the uterus very tender on pressure, and the temperature rose to 103.6°. Ordered flaxseed-meal poultice and salicylate of soda.

On September 20th the fundus was three and a half inches above the symphysis; pulse, 96, feeble; extremities cold. She vomited.

Five days later (September 25th) the fundus was yet three inches above the symphysis, and tender.

Ten days later (October 5th), the patient was still weak and downcast. The fundus was still three inches above the symphysis and a little sensitive on pressure. The lochia were no longer fetid; ice-bag.

On October 16th she sat up for the first time.

On October 20th, the twenty-sixth day after confinement, she passed, without any pain, more blood from her vagina, and a pear-shaped body, measuring 7.3 by 4 centimetres, exactly representing a cast of the uterine cavity. With exception of the part corresponding to the fundus, there ran a line of demarcation lengthways between the two halves, which, by slight pulling, were easily separated, showing that the specimen had been doubled up in the interior of the womb. It presented an appearance similar to the other specimens. The outer surface was gray, but the interior of the mass had the color of flesh. Everywhere were seen sinuses with thrombi. Microscopical examination showed that the whole mass was composed of uterine muscular tissue, the single fibres being in many places very large, as always in pregnancy, undergoing fatty degeneration, and interspersed with heaps of small round cells and sinuses filled with fibrin.

When I presented the first specimens a distinguished member said that in the last volume of the "Transactions of the Edinburgh Obstetrical Society," a series of such cases were reported, but neither he nor I, myself, have been able to find the article in question, and there was therefore probably some mistake about it. So far as I know, the disease has not yet been described as a feature of the puerperal state except by myself. All I have found in the literature about it are the two cases of the Russian physician, Siromjatnikow (*Centralblatt für Gynäkologie*, 1881, vol. v., p. 276), who tried to bring the disease in relation to a very problematic typhoid fever and to syphilis. But both his patients were puerperal, and the same was the case with all my eight cases and that of Dr. Kucher. In four of my cases there was diphtheritic inflammation of the vagina or cervix, and I feel much inclined to think that in the others a similar process went on unseen in the interior of the womb. This view is substantiated by an autopsy published in my article above referred to, in which there were no diphtheritic patches visible during life, but after death they were found in the interior of the womb, connected with a diphtheritic infiltration, which formed a layer extending out toward the subperitoneal part of the wall, by the melting of which a considerable part of the muscular tissue of the womb would have been cast off, exactly like the specimens I have presented.

The disease is at all events, as proved by the microscopical examination, an inflammation of the muscular tis-

sue, and must therefore be called metritis. It differs from *gangrene* or *putrescence of the uterus*, in which the destruction simply extends from the inner surface more or less deeply into the muscular tissue. It differs likewise from *endometritis desiccans* or *exfoliativa*, three cases of which are described by the Russian physician, Kubasow, in the last number of *Zeitschrift für Geburtshilfe und Gynäkologie*. In the latter disease it is the whole mucous membrane which is thrown off, in the shape of a sack, to the outer surface of which is attached in some places a very thin layer of the adjacent muscular tissue. The figures show that it is much thinner than the mucous membrane, and in one of the cases the author states that it measured only one-fourth of a millimetre. Two of his cases occurred in virgins and the third in a not pregnant married woman. Dissecting metritis, on the other hand, has so far only been observed as a puerperal disease.

DR. J. LEWIS SMITH presented specimens illustrating

MEASLES COMPLICATED BY CAPILLARY BRONCHITIS, after which the Society went into executive session.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, December 6, 1883.

FORDYCE BARKER, M.D., LL.D., PRESIDENT, IN THE CHAIR.

DR. T. GAILLARD THOMAS read a paper (see p. 646) on

THE PREVENTION AND TREATMENT OF PUERPERAL FEVER.

The paper being open for discussion, DR. W. M. POLK believed he echoed the voice of every Fellow when he said that we are deeply indebted to Dr. Thomas for the able and even eloquent presentation of this most important subject, and most of his views were too well recognized, and too generally accepted to require more than commendation on his part. Dr. Thomas had entered upon the subject so thoroughly that there was but little left to say, especially with reference to treatment. With regard, however, to the question of pathology, Dr. Polk thought that perhaps it would have been better, in view of the stress which the author of the paper laid upon antiseptic treatment, if he had planted himself squarely upon that pathological view which regards puerperal fever as identical with septicæmia and pyæmia. So long as there is any question on this part of the subject, it seemed to him that some doubt would still exist in the minds of many concerning the propriety of most of the remedial measures advocated by Dr. Thomas. So far as he was concerned, Dr. Polk was free to say that he considered the disease as identical with surgical septicæmia and pyæmia, and that the variations which exist in the clinical history or in the pathological lesions are simply those which are peculiar to the organs invaded. With regard to the view that there must be a special puerperal fever poison, or a multiplicity of poisons upon which the disease depends, Dr. Polk thought, if it were taken into consideration that a woman recently delivered had within her pelvis a large amount of rapidly retrograding material; that a large number of uterine and vaginal arteries, veins, and lymphatics were dilated and in places collapsed, giving areas of sluggish circulation; that the blood of such people, besides being deficient in red corpuscles (the oxidizing element) and containing an excess of fibrin, was so filled with waste material that its vital and chemical forces were often taxed to the utmost—then one could readily understand how an amount of septic poison, which in any other condition would be inoperative, would here be all-sufficient.

As to the question of treatment, standing as he did upon this basis of septicæmia and pyæmia, it seemed to him the principles of Listerism, as laid down by Mr. Lister and his followers, and advocated by Dr. Thomas,

entirely covered the ground. With regard to precautionary measures, there was absolutely nothing to be added. He would simply suggest, especially with reference to this city, that the question of purity of air is one which should be especially inquired into. Concerning measures of actual treatment, he had but a single suggestion to make, and it was this, that according to his experience intra-uterine injections had oftentimes been used when in reality the sole lesion which was killing the patient existed in the cervix. The stream of water, as it ordinarily flows from the interior of the uterus, is in many instances of insufficient weight to separate the closely applied surfaces, which are frequently in a sloughing condition. His rule, then, had been to thoroughly inspect, by means of Sims' speculum the entire vaginal canal as far as the external os, and then draw down the cervix with the tenaculum and separate its edges, and if he found that there was anything demanding attention, he applied directly to the spot a strong solution of carbolic acid, or some other similar strong disinfectant. In fact, in many cases it had been the only treatment which he had found necessary.

With regard to the interior of the uterus, if he did not find the vagina or cervix in conditions which seemed to be responsible for the disturbance, it had been a practice advocated to introduce borated cotton upon an ordinary applicator, wet in a strong solution of carbolic acid (two per cent.), into the interior of the uterus, and thoroughly wipe it out. He had introduced the broad curette (Skene's), when he suspected remaining portions of placenta or membranes, and removed whatever material might be found there. Of course his remarks were not at all at variance with the general principles advocated, but were simply items of personal experience concerning the details in carrying them out; but he believed that if we are to adopt the measures which have been so properly advocated by Dr. Thomas, we must go a little farther than the author of the paper had done and plant ourselves upon the ground that we have to do with a condition of things which differs in no essential respect from surgical septicæmia and pyæmia.

DR. JAMES B. HUNTER said that while Dr. Thomas had left but little to say, there were two or three points which he thought worthy of attention concerning the details of carrying out the method of treatment, and on which he should differ somewhat with the author of the paper. He had firm convictions with regard to the propriety of washing out the uterus, and was well aware of the great difficulty of accomplishing it thoroughly. He did not believe that *any nurse* should be trusted to administer the intra-uterine injections.

In the next place, it was important to disturb the patient as little as possible, and he thought this could be accomplished without moving the patient at all, if a bed-pan of large size is used, and the patient permitted to lie upon her back. He did not approve of the use of the Chamberlain tube of the size which had been exhibited, but preferred one of about half the calibre and half the length, and he had found it necessary to have the openings confined chiefly to the end of the tube. He had found that, after a few injections had been administered, the uterus contracts, so that it is difficult to pass a tube of large size into it. He then resorted to a smaller tube, and liked the silver tube of Dr. Lyman, or, what he had frequently used with more satisfaction, was Knott's double catheter. He had in some cases had occasion to dilate the canal before using the tube.

A point of special importance is regularity in carrying out this plan of treatment—thoroughness and gentleness without disturbance to the patient.

With regard to the effect produced by the injections, he had found, very commonly, fear of shock and other bad results, but he did not think these had at all been realized. Where the water had been used sufficiently warm, that is 100° F. to 110° F., the danger of chill was reduced to a minimum.

Again, when the water returns clear one is very apt to think he has made a mistake, but according to Dr. Hunter's experience, even though the water does come away clear, the temperature falls, showing the beneficial effects of the treatment. He had resorted to this method as late as the seventh week after parturition.

With regard to the use of the coil, he did not regard it as proper in simple puerperal septicæmia. In puerperal peritonitis he had the strongest possible confidence in it. He preferred the metal or Leiter's coil to the rubber coil, because he regarded it as more manageable, and as more easily kept clean.

DR. E. L. PARTRIDGE spoke with reference to a few practical points in the method of treatment. Concerning the pathology of the disease, he thought there could not be any essential difference in the minds of those who had had experience in the management of obstetrical cases. With regard to prophylactic treatment, he would impress the importance of personal cleanliness on the part of the medical attendant as strongly as Dr. Polk had spoken of the importance of the purity of the atmosphere. It is absolutely essential that the medical attendant observe the utmost strictness with regard to cleanliness, keeping the nails clean, etc., and as a prophylactic measure.

With regard to the management of the case after the disease is established, he was in favor of the use of intra-uterine injections, and would resort to them with the same frequency recommended. Concerning the agent employed, he had only to add that about one year ago the late Dr. Beverley Livingston introduced into the practice at the Nursery and Child's Hospital what Dr. Partridge believed to be a most excellent supplement to the intra-uterine treatment, namely, after cleansing the intra-uterine cavity, he used a mixture of iodoform and glycerine in the proportion of 1 to 10, and injected one, two, or three ounces into the uterine cavity after finishing with the uterine douche. Dr. Partridge regarded it as an excellent adjuvant, both in hospital and in private practice, and thought it possible that a certain amount of intra-uterine injection might be dispensed with by adopting this measure. With reference to the bichloride solution, he could declare himself in favor of its use. With regard to the coil, he believed in it for the reduction of temperature, and thought it the most efficient agent we have in our possession. He also thought we should not look for immediate and marked results from the plan of treatment, as Dr. Thomas had already stated. Again, absence of peritonitis is not a good reason why the agent should not be used. There is no area of the body where applications give the same results as when made over the abdomen. He favored, contrary to the opinion of Dr. Hunter, the rubber rather than the metal coil, and for precisely the same reason given by Dr. Hunter, namely, that it is more easily kept clean. In hospital practice he had not found any objections to its use arising from the patient *herself*, as to the liability to produce chilliness, etc., and he doubted if it produced any more discomfort than did the ordinary rectal injection administered for the first time.

THE PRESIDENT said the subject was a most important one, and, owing to the lateness of the hour, several gentlemen of large experience and competent to discuss the question were unable to have an opportunity to speak, and he therefore would suggest a proposition. Several years ago he himself advocated views with which not a single one present was in accord, and he had the pleasure and honor of presenting them to the London Obstetrical Society. But he thought that, at the present time, a very large number of prominent obstetricians in different parts of the world were in full accord with what he at that time expressed. The author of the paper of the evening did not consider it worth while to make allusion to these views, and inasmuch as he thought that opportunity should be given to have all views upon this important subject brought forward, and receive full discussion, he would propose that the subject of the paper be

made the topic of discussion at some future meeting of the Academy. With regard to the pathology of the affection, he should hold views which were at variance with those expressed by Dr. Thomas. He should accept in every particular the views expressed by the author of the paper so far as the description of septicæmia is concerned as it exists in the puerperal state, but he should differ with those stated concerning the sum total of the affection; that is, the various local inflammations which occur in the puerperal condition. So also with regard to several points in the treatment of these different conditions. He therefore suggested that the evening of the first meeting of the Academy in February be devoted to the discussion of this subject, and if it would not be regarded as improper he would ask the Academy that he be permitted to open the discussion.

On motion, the suggestion of the President was adopted.

DR. E. C. HARWOOD introduced a resolution, which was adopted, calling upon the delegates from the Academy of Medicine to the American Medical Association at its last meeting, held in the city of Cleveland, to report at the next regular meeting.

The Academy then adjourned.

Correspondence.

KAIRINE IN TYPHOID FEVER AND ALBUMINURIA IN INTESTINAL HEMORRHAGE.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In the recent discussion on typhoid fever at the Academy of Medicine I alluded to the value of kairine in controlling the temperature of typhoid fever, and to the appearance of albumen in the urine when intestinal hemorrhage occurred. I have been requested to give more in detail my experience with kairine, and likewise my authority for the statement as to the appearance of albumen in the urine after intestinal hemorrhage.

There are three varieties of kairine in the market, namely, kairine M. (or methylic), and kairine E. (ethylic), and kairine E. (ethylic), (W. Filehne, *Berlin. Klin. Woch.*, No. 6, 1883). Kairine M. is given in doses of 7.5 to 15 grains. The temperature is rapidly lowered, and rises very rapidly. The effect of the administration of 15 grains of kairine M. passes off in about three hours. Profuse sweats appear on the beginning, and cease with the action of the remedy. The temperature then rises rapidly.

The effects of kairine E. (kairine E. is said to act in the same way) are said by Filehne to persist for some six hours when administered in doses of 20 to 30 grains. Sweats occur as with kairine M. At the end of the six hours the temperature gradually rises. Filehne made many trials in acute and chronic febrile troubles and obtained always the same results.

He advises the use of kairine E., since the administration of it is more easily managed and the effects more lasting. He prescribes it in the following manner: The first day of any disease when antipyretics appear indicated, the temperature should be taken every two hours, and when it is decided to administer the remedy, $7\frac{1}{2}$ grains are given every hour until four doses have been taken; or, more exactly, this amount is administered until the temperature falls to 100.4° F. This result obtained, he gives from hour to hour only $3\frac{1}{2}$ grains, but as soon as the temperature begins to rise, or the patient complains of a chilly sensation, he resumes the administration of $7\frac{1}{2}$ grain doses. If hourly doses of $7\frac{1}{2}$ grains do not lower the temperature, the amount given hourly is increased to 10 or 15 grains until the temperature is lowered to 100.4° F.

I had not read the communication of Filehne when I first made use of kairine, and I was not then aware that there were several varieties of kairine. The method of

administration that I adopted was to begin with 7 grains of kairine, and have the temperature taken every hour. Unless the temperature was above 102° F. I did not regard the remedy indicated, but when the temperature was above this point I had the remedy administered and the temperature taken hourly. If after the first dose the temperature began to fall, say $\frac{1}{2}^{\circ}$ to 1° in the hour, I continued the drug in doses of $3\frac{1}{2}$ grains every hour or half hour, and as soon as the temperature had fallen to 101° F. I discontinued the medicine, and directed that the temperature be taken every hour or two, and that on the slightest indication of a rise of temperature that $3\frac{1}{2}$ or 7 grains be administered at once, and repeated as often as necessary.

I do not believe it wise to reduce the temperature below 101° , since, if the temperature is quickly reduced to a lower point it is more apt to rise rapidly, and if not, you may have some of the signs of collapse appearing—cold extremities, failing heart action, cyanosis, etc.

Moreover, if the temperature has been brought down to 101° the amount of tissue destruction will not be very great at that degree, and cardiac paralysis will certainly not be likely to occur.

Considerable attention has been given to the occurrence of chills during the administration of kairine, and this has been regarded as a very great objection to the use of the remedy, and indeed the chills have been regarded by some as having been induced by the drug. Bear in mind that there are two kinds of chills—one, well called a "nervous chill," which is often observed in hysteria, spinal irritation, and which is also observed in a certain form of epilepsy, but in these chills there is no rise of temperature, or no rise of over 100° F. The second variety, which *always*, I may say, accompanies the rapid rise of temperature. Given any disease in which the temperature rises above 102° F. in a few minutes or an hour, and you almost invariably find that a chill has occurred, and if closely watched it will be observed that the rise of temperature to a certain extent has preceded the chill—has been present throughout the cold stage. The peripheral temperature may be low, but the oral, rectal, urethral, and vaginal temperature will always be found high. The axillary temperature cannot be depended upon. The occurrence of a chill in any fever, as typhoid fever, treated by kairine, will always be found as succeeding and accompanying a rise of temperature. If a close watch be maintained as to the exact degree of temperature of the body, the early administration of kairine will prevent the occurrence of a chill.

The kairine which I have used has been the kairine E., and I am not aware that kairine M. can be found in this city.

It seems to me, however, that it is very important that the profession should know which form of kairine they are using, and be sure that the preparation is a good and pure one. I have come to look upon kairine as one of the most valuable antipyretics that we possess, and I trust that its use will be greatly extended.

I have transgressed much upon your space, and shall advert briefly to the appearance of albumen in the urine on the occurrence of intestinal hemorrhage in typhoid fever.

I remember having my attention directed to this matter some years ago, when in the hospital, I think. During the discussion of Dr. Delafield's paper, I asked how soon after intestinal hemorrhage albumen appeared in the urine, hoping to hear something on the subject from those present, but I did not succeed. Since then I have searched for some account of it, but have only the testimony of some three physicians as to its occurrence.

Very truly yours, T. A. McBRIDE, M.D.

47 EAST TWENTY-FIFTH STREET.

MEASLES IN WASHINGTON SCHOOLS.—Several schools in Washington have been closed on account of the prevalence of measles.

THE CHANCES OF THE YOUNG PRACTITIONER AND THE ADVICE GRATIS SYSTEM.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Will you kindly allow one of the younger members of the profession—who can, however, lay claim to the title of practitioner only by a species of *lux a non lucendo* courtesy—to extend to you his hearty thanks and congratulations upon the manly stand taken by your journal in the recent editorial upon the “Advice gratis system” and its *mélange* of abuses. We have all heard of the Irishman who endeavored to impress upon a credulous and somewhat myopic horse, through the medium of colored glasses, that a meal of shavings was as satisfactory as one of oats, with the usual result—“the operation was successful, but the patient died.”

The experience of the past few years of my life has evolved in me a most sympathetic and kindly feeling toward that horse. You will hence, I feel sure, pardon any “Green grow the glasses o’er me” expressions, or *morituri salutamur* symptoms which may be apparent in what I have to say.

The correspondent in your last issue (whose signature as one of the young practitioners, let us hope, is not so much a figure of speech as it would be in my own case) states very forcibly the truth, that any ameliorative action must come from the younger members of the profession. I think he will agree with me that any such action must be universal and constant, as well as decided, to accomplish any result. I also think he will agree with me that it would be bravado, and not intrepidity, in any one to hope or attempt to constitute himself a leader by *merely* resigning any position which he may believe helps to bolster up this crying outrage, or, indeed, by any spasmodic outburst of well-meaning but necessarily ineffectual enthusiasm. This would doubtless receive from the dignified Bumbles of the profession the same measure of success that greeted poor Oliver Twist’s plaintive request, “Please, sir, I want some more.” Though we may be the exact analogues of the pitiable “workus” lad, though we may be “desperate with hunger and reckless with misery,” we shall certainly get no “more” by the “commission of such an impious and profane offence.”

Plainly, all reform in this direction must be gradual, and—we may as well recognize it—slow. What we must all work for is to make it sure. The unfortunate phase of the subject is that the contest which thinking men admit is inevitable is not to be decided by one blow, or even one united effort, but by a persistent, continuous, conscientious struggle; and, what is hardest to accept philosophically, is that the benefits will accrue to those who follow us, and not to ourselves.

The evils of our present charity system are easily traced to the naturally fierce competition in an overcrowded profession, and to our national anxiety to obtain a short cut to fame and fortune. The solution of the whole difficulty is merely to put down the brakes on each. If we can do that, we can do all. The task is hard, but not impossible. The present agitation about State examining boards is a hopeful sign. The mills of diplomas, like the mills of the gods, must be made to “grind slowly and grind exceeding small.” It is worse than a farce, it is a disgrace, that, because it is considered the best and most ethical advertisement for a man to be a professor in a medical college, that medical colleges must exist to advertise the professors. Policlinics, polyclinics, post-graduate and practitioners’ schools, sprout up in profusion to give the finishing touches to the crude material the colleges claim to have educated, and I suppose ere long there will be post-polyclinics, with a corps of professors and a large clinical *clientèle*. Now colleges mean clinics, dispensaries mean clinics; these obliging schools which will make over the aged practitioner as good as new mean clinics, and—here’s the rub—clinics mean ma-

terial, and material means money from the pocket of the young doctor.

In one of Elia’s most piquant essays, the human species is divided into “those who borrow and those who lend.” Now it would not require an extraordinary knowledge of algebra for one to go the imaginative *littérateur* one better, and calculate, from the present rate of production, the exact date at which the population of the world will consist of equal parts of medical profession and clinical material—each doctor enthusiastically holding his individual clinic upon his own individual patient, while those lucky individuals who preside over a twin confinement, appoint the mother janitor, to open a medical college.

I have already transgressed too freely upon your valuable space; I should like, however, to offer one more suggestion, which is simply this: That it is not alone in the indiscriminate gratuitous treatment of patients that our charities are at fault, but likewise, and perhaps equally, in the gratuitous treatment of the physicians who do the drudgery part of the work. No doctor, no dispensary, no hospital, has any more right to expect (what we tacitly allow them to claim) gratuitous services from a legally qualified practitioner of medicine, than they have from a member of any other calling. It is “whipping the devil around the stump” in the most barefaced manner to pretend in an unctuous and owl-like manner, “That these gentlemen who compose our hospital house-staffs and clinical *corps* get an adequate return in training and experience; it is really a part of their education.” Granting that it is, the colleges are at fault. But look at the other professions: when their members are licensed, they claim a fee for their services and get it. The young theologian gets his hand in as chaplain at a hospital, the young lawyer draws up the papers for a damage suit in the wards. They get valuable experience, and what is more, they get paid for their crude efforts. The attending doctor even gets a fat fee from a private hospital patient, while the interne, who has the immediate personal care, responsibility, and the larger part of the treatment, gets—rarely, a “Thank you.”

THE MEDICAL RECORD has started a good work, and may God speed it. Young men are beginning to think for themselves, if the fact that they are almost unanimously opposed to any and all codes has any significance. They respectfully, but firmly, decline to impale themselves upon either horn of the dilemma so assiduously proffered them. All they want is a “fair field and no favor.” Let THE MEDICAL RECORD stand by and see fair play.

M. D.

FAILURE OF THE HOT-WATER DOUCHE IN THE TREATMENT OF A CASE OF POST-PARTUM HEMORRHAGE.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: The use of hot water as a hæmostatic, especially in hemorrhage after parturition, is coming to be pretty generally recognized by the profession. Many of its advocates, however, appear to me to regard it as infallible in its effects, and not without some justification if one were to judge from the number of successes recorded. But I am not sure that cases of failure are as industriously brought to the knowledge of the profession as frequently as they occur, and therefore I hope you will consider the following history of sufficient interest to lay before your readers:

Mrs. K—, aged twenty-nine; primipara. Has always enjoyed excellent health and is of good constitution. Was delivered of twins at 7 A.M. July 14, 1883, after a labor of four hours. Gave 3 jss. of ergot (fl. ext.), which was followed by expulsion of placenta in fifteen minutes and firm contraction of uterus. I was suddenly summoned at 1 P.M. and found slight amount of blood flowing from vaginal orifice; removed binder immediately and found uterus enlarged to nearly midway between umbilicus and ensiform cartilage. Gave ergot by mouth and hypodermically, cleaned the uterine cavity of clots,

and performed pressure over fundus with little effect. Then water as hot as could be borne was injected in large quantity, which was followed by good contraction, but in short time relaxation took place. The douche was again tried and followed by contraction and relaxation as before. Becoming exhausted by my efforts at douching and pressure on fundus, I sent for assistance. Hot water was now used a third time, but with no better result than on the two previous occasions, notwithstanding the constant and powerful pressure of Dr. Martin Burke, who assisted me. About three ounces of tincture of iodine were now thrown into uterus, with the same result as followed the use of hot water. We finally had recourse to electricity, with the effect of causing firm and continuous uterine contraction. Found it safe to leave patient at 4 P.M., after applying a compress over fundus strapped down tightly with adhesive strips, with binder over all. Patient after this did well.

THOS. J. KEARNEY, M.D.

107 LEXINGTON AVENUE, NEW YORK.

Army and Navy News.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from December 1 to December 8, 1883.

CARTER, W. F., Captain and Assistant Surgeon. Relieved from duty at Washington Barracks, D. C., to take effect at the expiration of his present leave of absence, and assigned to duty at Little Rock Barracks, Arkansas. S. O. 224, par. 4, Department of the East, November 30, 1883.

SHUFELDT, R. W., Captain and Assistant Surgeon. Now on sick leave, relieved from duty at Jackson Barracks, New Orleans, La. S. O. 224, par. 3, Department of the East, November 30, 1883.

RICHARD, CHARLES, First Lieutenant and Assistant Surgeon. Assigned to duty at Jackson Barracks, New Orleans, La. S. O. 224, par. 2, Department of the East, November 30, 1883.

Official List of Changes in the Medical Corps of the Navy, for the week ending December 8, 1883.

KINDLEBERGER, D., Medical Inspector. Ordered to the U.S.S. Hartford, Pacific Station, per steamer of the 10th inst.

GIHON, A. L., Medical Director. Detached from duty as Member of Board of Inspection and Survey on the 15th inst., and placed on waiting orders.

PECK, GEORGE, Medical Director. Ordered to report on the 15th inst. as Member of the Board of Inspection and Survey.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending December 11, 1883:

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.

December 11, 1883.....	0	4	8	3	6	28	0	0

THE STRUGGLES OF A YOUNG DOCTOR.—A correspondent writes: "In the town in which I am located we have twelve physicians and enough patients to go around, and myself and two other young physicians could do well enough but for a crime the older ones have committed, and are still committing, against the well-being and dignity of the profession. They prescribe for fifty cents and furnish from one- to six-ounce mixtures, either giving themselves away or the medicine. They make calls for one dollar and furnish medicines most of the time. They trust patients, and continue to do business for them, when accounts have not been settled for years. Of course they abuse us, patronize us, consult with us (the last is the worst, for we are very apt to lose our patient when they do), and sometimes let us assist at a surgical operation. We, on the other hand, are obliged to collect our bills in order to live, and so have adopted the rule of sending bills every thirty days; we charge the same fees without furnishing the medicine, and can you blame us if we retort upon their stories of drug clerks' mistakes, by stating our belief that their drugs must be poor, and that the patient has often to take what the doctor has in his office, not what would be the best thing for him. Lest this locality should be recognized, I would say there is one honorable exception, one who charges as is his right, is kind and just to the young men, and honest with his patients. Can you wonder, Mr. Editor, that in this place the physician is not treated with the respect due to his profession? Here his standing is something between that of a man who labors and the village storekeeper."

HINTS FOR MEDICAL STUDENTS.—According to the *Boston Medical and Surgical Journal*, the following was found posted on the bulletin board of the Harvard Medical School after the late examinations: "Dr. Edes wishes to call the attention of the graduating class to the following facts, which may be important to them and their patients. The doses referred to are NOT all from books which failed to receive 50 p. c. The following are too large doses: Half a grain of morphia, ten drops of Fowler's solution, to begin with; 10 c.c. of fl. ext. of conium; calomel, 7 grams; $\frac{1}{8}$ or $\frac{1}{4}$ grain of sulphate of atropia; 1 gram of sulphate of copper; half a gram of aloes every night, in habitual constipation. The following would make inconveniently large pills: One gram of pil. aloes et myrrh (no such pill made is officinal); 390 grams of sulphate of quinine and 130 grams of confection of roses made into six pills; 7 grams of calomel and 6 centigrams of blue mass. Pepsine and bismuth should not be given together. Lactopeptine is less efficient than pepsine. A teaspoonful of lime-water in a tumbler of milk does neither good nor harm. Calomel should not be used as an habitual cathartic (as was recommended in a good many books). Mercury alone cannot conveniently be made an ingredient of an extemporaneous pill. Blue-pill does not contain calomel. An apothecary cannot reasonably be expected to go out and kill a pig to make fresh pepsine for each prescription that comes in."

THE DIAGNOSTIC VALUE OF THE TUNING-FORK IN AURAL DISEASE.—Dr. Charles H. Burnett, of Philadelphia, after giving the conclusions on the above subject from a paper read by Dr. Sexton, before the American Otological Society, July 17, 1883, submits some original and practical reflections on the erroneous deductions made from the use of the tuning-fork, regarding the nature of aural disease, especially in reference to so-called cochlear inflammation, supposed disease of the auditory nerve, and altered perception of sound in syphilitic disease of the ear. Burnett thinks the phenomena of the vibrating tuning-fork when placed on the head or teeth have been misunderstood, and that false conclusions have been drawn in considering that the results thus obtained are reliable data for estimating the *perceptive* power of the nerve, rather than the *conductive* power of the auditory apparatus in the external and middle ear.

He therefore concludes that in the attempt that has been made to "establish" the existence of a "syphilitic cochlitis," the so-called acoustic phenomena may be accounted for much more easily by the supposition of altered conduction by reasons of changes in the mucous membrane, so well known to occur in syphilis, than by the difficult and entirely untenable view that the changes in audition are due to alteration in the nerve, and hence are phenomena of altered perception. This endeavor to remove the diagnosis from the nearer and more probable ground to a remoter and less known one has been not only unnecessary, but misleading; unnecessary, because the experiments of Helmholtz, Politzer, Buck, Hensen, C. H. Burnett, and McKendrick, upon the mechanism of the ossicles, and their relation to audition have been demonstrable *ad oculos* and have made clear the phenomena of condition of sound and how it may be interfered with; whereas we now know positively nothing about the mechanism of perception of sound in the labyrinth. Considering these statements to be correct, the endeavor to refer phenomena most probably occurring in the tympanic cavity, and attributable to changes in the conductive region, to a part of the ear unknown, excepting that it is concerned in all probability with perception, cannot but be regarded as unscientific, and misleading to younger minds. Moreover, it by no means follows that, because in the sudden deafness in syphilis a patient has been cured by an antisiphilitic remedy, that the disease lay in the cochlea and was due to "cochlitis," since it would be just as much proof, perhaps more, that the disease lay in the mucous membrane of the drum cavity, or of its contents, and, by interfering with sound conduction, had caused deafness, and that the latter had been removed by the anti-syphilitic action of the drug upon the mucous membrane. The writer furthermore believes that were we to encounter inflamed cochlear nerve-tissue, a cure could not be so easily accomplished as has been claimed, by any remedy, or, if the disease were removed, hearing would not be under such circumstances either quickly or completely restored.

THE USE OF THE RECTAL LEVER IN AMPUTATION OF THE THIGH.—Mr. Crowell, of Westminster Hospital, recently amputated through the left hip-joint for old-standing disease of that articulation. The common iliac artery was successfully compressed by Davy's rectal lever. Only four ounces of blood were lost. The patient is reported to be progressing favorably. Recently Mr. Turner tied the right gluteal artery at the Seamen's Hospital, Greenwich. Mr. W. Johnson Smith communicated the following note on the case to the *British Medical Journal*: "Mr. Turner's patient was the subject of a very extensive traumatic aneurism of the gluteal artery, which vessel it was thought necessary to expose by dissection so as to tie it above and below the opening. As the patient was old, and had been much weakened by hemorrhage, it was very necessary to do all this without causing much further loss of blood; and as the abdominal compressor is an uncertain instrument, and likely by itself to cause shock, the operation on this patient would have been difficult, if not impossible, without the use of Davy's lever. This was applied, by the house surgeon, with thorough success. We saw the opening in the artery, and the double ligature was applied in an almost bloodless wound, and, beyond the blood already extravasated into the sac of the aneurism, there was not a further loss than of, at the most, half an ounce."

A SCHOOL FOR RICKETY CHILDREN.—Mr. Bernard Roth, of London, gives an interesting account in the *Lancet* of a school for rickety children, in Milan, Italy. He writes: "I paid in 1877 a long visit to the school for rickety children in Milan (Pio Istituto dei Rachitici in Milano), which is under the able medical superintendence of my friend Dr. G. Pini. The object of this school and of the similar one at Turin is to have rickety

and deformed children under regular daily treatment for some years during school life. The afflicted children are fetched daily by omnibuses from the various public schools, and returned the same evening to their homes. At the School for Rickets a portion of each day is devoted to special orthopædic treatment by "medical gymnastics," rubbing and splints where necessary, while the rest of the day is devoted to lessons under certificated teachers, and to out-door games in a spacious playground. The children are also fed at the school, and receive the diet most suitable for rickets—viz., plenty of milk, phosphates, cod liver oil, etc., according to each case. Forty children were present at my visit; most of them had more or less severe rickety deformities of the extremities, but I saw one case of severe spinal caries, and another of severe lateral curvature. Children as young as two years of age are received. There is a well-arranged bath-room on the premises. I noticed several rocking-horses and three different sizes of tricycles for the use of the children. Froebel's Kindergarten educational system is followed as far as possible.

PLASTIC CLAY FOR SUPPOSITORIES.—The use of plastic clay as a convenient material for suppositories in some cases is recommended by Dr. Trippier (*L'Union Pharmaceutique*, xxiv., 398). The ordinary sculptor's modelling clay is used, the medicaments being dissolved in water and then worked into the mass; in this way salts of iron and copper, alum, or even vegetable extracts may be incorporated by taking proper precautions. It is proposed to supply patients with the medicated clay, so that they can break off a portion and mould it between the fingers as required. There are difficulties in the way of maintaining the proper consistence. These accidents may be overcome by keeping the clay under a bell-glass in a moist atmosphere, or by the employment of glycerine, which is also said to have the additional advantage of giving stability to a mixture containing iodide of potassium. The formula for such a mass is: clay, 500 grammes; water, 50 grammes; potassii iodidi, 30 grammes; glycerine, 100 grammes.—*Pharmaceut. Journ.*

PREMATURE SEXUAL DEVELOPMENT.—The following interesting case is reported in the current number of *Amer. Jour. of Obstetrics*: Child now two years seven months old, began to menstruate when four months old. Flow comes regularly every twenty-eight days, and lasts four or five days. She weighs forty-nine pounds. Has features and form of a girl ten or twelve years old. Mammary glands as large as small oranges. The mons veneris is well developed and covered with a full growth of hair. The external labia large, and all parts of the vulva fully formed. All functions seem to be performed normally. Has never shown any disposition to handle her parts or masturbate in any way. Is quite modest with her mother, and particularly so with her father. Her tastes belong to a child much older. She is bright and intelligent, but easily irritated, especially at the beginning of the menstrual epoch. Parents not related. Family history good. No other case of the kind ever known in family. Her future sexual history will be very interesting. At what age can the menopause be expected? In a Brooklyn Museum the "Baby Venus" is on exhibition. She is a child three years old, weighs sixty-five pounds, health perfect, has never been sick, features of a young lady, and mammary glands fully developed. Pelvis and vulva much more fully developed than in children of her age. Has never menstruated. In our last number we mentioned two cases of temporary sexual development in children, caused by local irritation and reflex action it was thought. These two cases have no local cause and are permanent.

CHLOROFORM AND CARBONATE OF AMMONIA IN LABOR are recommended by Dr. W. C. Van Bibber (*Maryland Medical Journal*). Dr. Van B. thinks that the combination is safer and less depressing than chloroform alone.

CEREBRO-SPINAL FEVER.

(SPOTTED FEVER. CEREBRO-SPINAL MENINGITIS.)

By J. LEWIS SMITH, M.D.,

CLINICAL PROFESSOR OF DISEASES OF CHILDREN, BELLEVUE HOSPITAL MEDICAL COLLEGE.

(Continued from p. 646.)

Prognosis.—Cerebro-spinal fever is justly regarded as one of the most dangerous maladies of childhood. It is dreaded not only on account of the great mortality which attends it, but on account also of its protracted course, the suffering which it causes, the possible permanent injury of the important organ which is chiefly involved, and the not infrequent irreparable damage which the eye and ear sustain.

I have the records of the result in 52 cases which I attended or saw in consultation in the epidemic of 1872. Of these just half recovered. Sixteen of the twenty-six who died were hopelessly comatose within the first seven days, most of them dying within that time, and some even on the first and second days, while others of the sixteen lingered into the second week and died without any sign of returning consciousness. The remaining ten, who subsequently died, but did not become comatose in the first week, were nevertheless seriously sick from the first day, but their symptoms, though severe, were not such as necessarily indicated a fatal result, so that there was some expectation of a favorable ending till near death, which occurred for the most part from asthenia. One succumbed to purpura hæmorrhagica, the hemorrhages occurring from the mucous surfaces, and two died after a sickness of more than two months, in a state of extreme emaciation and prostration. The twenty-six who recovered convalesced slowly and usually after many fluctuations.

Their highest temperature and most severe and dangerous symptoms occurred in the first week. Most of them were several weeks under observation and treatment before they sufficiently recovered to be out of danger. The statistics of this epidemic therefore show, and the same is true of other epidemics, that the first week is the time of greatest danger, and if no fatal symptoms are developed during this week recovery is probable with proper therapeutic measures and kind, intelligent, and efficient nursing, the latter of which is very important.

Since the epidemic of 1872 I have treated, or seen in consultation, 35 cases that I was able to follow to the close, most of them in the last four years. Of these 19 recovered and 16 died. Of the 16 fatal cases 8 died in the first week, 5 in the second week, 1 on the twenty-fifth day, 1 on the thirty-first day, and 1 in the sixteenth week. This last patient, a boy of ten years, would, in my opinion, have recovered with better nursing. His death occurred from large bed-sores which extended to the bones, produced, though attended by his mother, by lying a long time in one position on a hard bed when he was too weak to move, and often with soiled bed-clothes underneath him.

There is probably no disease which falsifies the predictions of the physician more frequently than cerebro-spinal fever. This is due partly to the severity of the cerebral symptoms in the commencement, which, did

they occur in other forms of meningitis with which he is more familiar, would justify an unfavorable prognosis, and partly to the remissions and exacerbations, the occurrence alternately of symptoms of apparent convalescence and recrudescence or relapse, which characterize the course of this malady. Grave initial symptoms, which may appear to have a fatal augury, are often followed by such a remission that all danger seems past, and in a few hours later, perhaps, the symptoms are nearly or quite as grave as at first.

Under the age of five years, and over that of thirty, the prognosis is less favorable than between these ages. An abrupt and violent commencement, profound stupor, convulsions, active delirium, and great elevation of temperature, are symptoms which should excite solicitude and render the prognosis guarded. If the temperature remain above 105° death is probable, even with moderate stupor. Numerous and large petechial eruptions show a profoundly altered state of the blood, and are therefore a bad prognostic, and so is continued albuminuria, since it shows great blood change, or nephritis, while other organs than the kidneys are probably also involved. In one case, a boy, whom I examined nearly a year after the cerebro-spinal fever, the kidneys were still affected. He had anasarca of the face and extremities, with albuminuria. Chronic Bright's disease had occurred from the acute nephritis, which complicated cerebro-spinal fever. Profound stupor, though a dangerous symptom, is not necessarily fatal so long as the patient can be aroused to partial consciousness and the pupils are responsive to light; so long as it does not pass into actual coma it is less dangerous than active or maniacal delirium, which is apt to eventuate in this coma.

A mild commencement, with general mildness of symptoms, as the ability to comprehend and answer questions, moderate pain and muscular rigidity, some appetite, moderate emaciation, little vomiting, etc., justify a favorable prognosis, but even in such cases it should be guarded till convalescence is fully established.

We may repeat and emphasize the important fact shown by the above statistics, that patients who live till the close of the second week without serious complication will probably recover. The danger after this period is, in most instances, from exhaustion and feeble action of the heart, resulting from the impaired nutrition and protracted course of the disease.

Complications, which most frequently pertain to the lungs, increase greatly the gravity of many cases and contribute to the fatal ending. The fact that Webber, in his prize essay, describes a variety of cerebro-spinal fever which he designates pneumonic, and that those who make post-mortem examinations find that "cedema, hypostatic congestion of the lungs, bronchitis, atelectasis, and broncho-pneumonia, are extremely common lesions in cerebro-spinal meningitis" (Welch), indicates a source of danger in addition to that located in the cerebro-spinal system. One close observer of an epidemic writes: "In all the fatal cases which came under my notice, the most prominent symptoms which preceded death were those which indicate impairment and perversion of the respiratory functions. As the breathing became more hurried and difficult, the general depression became more intense, the pulse became weaker and quicker, and the temperature of the skin more elevated."

Parenchymatous degeneration of the liver and kidneys

is another serious complication. The kidneys are probably more frequently, and to a greater extent, diseased than the liver. Acute diffuse nephritis was present in one of the eight cases examined after death by Prof. Welch. In the *Revue Médicale* for June 3, 1882, M. Ernest Gandier published the case of a female who died comatose on the sixth day of cerebro-spinal fever. Examination of the urine had revealed the presence of "retractile albumen of Prof. Bouchard, attributable to renal lesions, and non-retractile albumen, considered as an indication of some general infection of the system." Microscopic examination of the kidneys "showed considerable swelling and granular degeneration of the renal epithelial cells, with effusion of granular matter within the lumen of the tubules." We have seen from the case alluded to above that the renal complication may persist and become chronic. Those who fully recover often exhibit symptoms usually of a nervous character, as irritability of disposition, headache, etc., for months after convalescence is established.

Diagnosis.—Cerebro-spinal fever, on account of the nature and severity of its symptoms and the suddenness of its onset, may be mistaken for scarlet fever, and *vice versa*. In one instance, to my knowledge, this mistake was made. High febrile movement, vomiting, convulsions, and stupor, are common in the commencement of scarlet fever, and the same symptoms commonly usher in the severer forms of cerebro-spinal fever. It will aid in diagnosis to ascertain whether there be redness of the fauces, for this is present in the commencement of scarlet fever, and a few hours later the characteristic efflorescence appears on the skin.

The diagnosis of cerebro-spinal fever from the common forms of meningitis is ordinarily not difficult, for while in the former the maximum intensity of symptoms occur in the first days, in the latter there is a gradual and progressive increase of symptoms, from a comparatively mild commencement. Moreover, cases of ordinary or sporadic meningitis occurring at the age when cerebro-spinal fever is most frequent, are commonly secondary, being due to tubercles, caries of the petrous portion of the temporal bone, or other lesion, and are therefore preceded and accompanied by symptoms which are directly referable to the primary disease. We have seen how different it is in cerebro-spinal fever, which in most patients begins abruptly in a state of previous good health. Again, in cerebro-spinal fever, after the second or third day, hyperæsthesia, retraction of the head, and other characteristic symptoms occur, which are either not present or are much less pronounced in ordinary meningitis. Some of the milder cases of cerebro-spinal fever might be mistaken for hysteria, but the pain in the head and elsewhere, muscular rigidity, and especially the occurrence of more or less febrile movement, enable us to make the diagnosis. Continued fever, typhus or typhoid, resembles cerebro-spinal fever in certain particulars, but it lacks the muscular contraction and rigidity which characterize the latter. It does not usually begin so abruptly, with such severe symptoms, especially such severe headache, has less marked fluctuations, and a more definite duration. These facts, in connection with the character of the prevailing epidemics, will enable us to make the diagnosis. In one instance commencing retro-pharyngeal abscess, probably associated with vertebral caries, was at first mistaken by me for cerebro-spinal fever. The patient was an infant, had a temperature of 104, stiffness of the neck with some retraction of the head, and cried from pain when the head was brought forward. The speedy occurrence of two large abscesses in other parts of the system, difficult deglutition and noisy respiration, led to a digital exploration of the fauces, when the abscess was found and lanced.

Treatment.—Since in epidemics of cerebro-spinal fever cases are most frequent and severe where anti-hygienic conditions exist, it is evident that measures looking to the removal of such conditions, measures designed to

procure pure air in the domicile, wholesome diet and a quiet and regular mode of life, in fine, measures designed to produce the highest degree of health, are of the first importance for the prevention of the disease. Cleanliness of the streets and areas, as well as apartments, perfect sewerage and drainage, the prompt removal of all refuse matter, avoidance of over-crowding; in a word, the strict observance of sanitary requirements in every particular, will, there can be little doubt from what we know of the causation and nature of cerebro-spinal fever, diminish the number and severity of the cases. The avoidance of fatigue and overwork, of mental excitement, the use of plain and wholesome diet, sufficient sleep, the utmost regularity in the mode of life with the least possible exposure to depressing agencies, are the important preventive measures which should be recommended wherever an epidemic of cerebro-spinal fever is occurring.

It is probable that the young man who, still weak from an attack of typhoid fever, applied himself closely to his business, of a perplexing nature, which had suffered from his absence, and in a few days was seized with headache and vomiting and soon died of this malady, would have escaped by a more prolonged rest, and less mental excitement and worryment. It has seemed to me that those children whose cases are embraced in my statistics, that left home in the morning entirely well, and when engaged in their studies, subject to the noise and discipline of the public schools, which is often too severe and rigorous for sensitive children, were attacked with this disease, would probably have escaped in the quiet of their own homes. The girl that, failing of promotion in her school, returned home crying, and closely applied herself to her studies till she was compelled to desist by the severe headache which ushered in cerebro-spinal fever, perhaps would have remained well had her experiences in the school been more pleasant and less depressing. In a similar manner the two children that were attacked with cerebro-spinal fever immediately after mild punishments which they had received, but which produced mental excitement, perhaps would have escaped under less severe family discipline.

The enjoining of a quiet and regular mode of life as a preventive measure, during the occurrence of an epidemic of cerebro-spinal fever, is not inconsistent with the theory that the cause is a micro-organism. It is not unreasonable to suppose that the system may be more or less under the influence of the specific principle, that this principle may obtain lodgment in the blood or tissues without result until some exciting cause occurs which depresses the system and disturbs the functions, when the resisting power fails and cerebro-spinal fever appears; just as those exposed to Asiatic cholera may remain well until some imprudence in the diet or the mode of life causes an outbreak of the malady.

Curative treatment.—In the commencement of cerebro-spinal fever, intense inflammatory congestion occurs of the cerebral and spinal meninges, and also to a certain extent of the brain and spinal cord. As regards treatment, the obvious indication is to reduce the hyperæmia of the vessels as quickly as possible and subdue or diminish the inflammation. For this purpose bags or bladders of ice should be immediately applied over the head, and to the nucha, and constantly retained there as long as there is no complaint of chilliness, no marked diminution of the temperature, and the patient experiences some relief from the intense headache and other symptoms. Bran mixed with pounded ice produces a more uniform coldness and is sometimes more agreeable to the patient than the ice alone. The bag or bags should be about one-third full, so as to fit upon the head like a cap, and the nurse should be instructed to renew the ice as soon as it melts. In severe cases, with marked elevation of temperature, it is proper to apply cold over the dorsal and lumbar vertebrae, as well as upon the head and nucha. A hot mustard foot-bath or a general warm bath in those

cases in which convulsions are present or threatening, or there is delirium or great agitation or severe peripheral pains, is also useful, since it has a calmative effect and acts as a derivative from the hyperæmic nerve-centres. One writer states that he obtained marked benefit in a case by immersing the body to the neck in hot water.

The abstraction of blood, usually by leeches applied to the temples, behind the ears, or along the spine, has been employed, but even in the commencement of the present century, when it was customary to bleed generally and locally in the treatment of inflammatory and febrile diseases, a majority of the American physicians whose writings are extant discountenanced the use of such measures in the treatment of this disease. Drs. Strong, Foot, and Miner, though under the influence of the Broussaisian doctrine, were good observers, and they soon abandoned the use of the lancet and leeches in the treatment of these patients for more sustaining measures. Strong, who published a paper on spotted fever in the *Medical and Physiological Register*, in 1811, states that certain physicians employed venesection as a means of relieving the internal congestions, but finding that the pulse became more frequent after a moderate loss of blood, they soon laid aside the lancet. Some experienced physicians of that period, however, continued to recommend and practise depletion, general as well as local, as, for example, Dr. Gallop, who treated many cases in Vermont, in the epidemic of 1811.

Venesection in the treatment of cerebro-spinal fever is universally discarded at the present time in this country and in Europe, but some intelligent physicians, as Sanderson and Niemeyer, approve of local bleeding in certain cases. It is, in my opinion, after examining the histories of many cases, uncertain whether the abstraction of blood should ever be recommended, but if it be prescribed, it should be on the first day, when the hyperæmia is greatest, by the application of only a few leeches behind the ears, and never except when convulsions or coma are present or threatening, and the patient is robust. The fact should not be forgotten that cerebro-spinal fever is in its nature asthenic and protracted, and that the intense inflammatory congestion of the nervous centres can ordinarily be relieved, if relieved at all, by the other measures recommended, which do not reduce the strength. The alarming symptoms which usher in an attack, the intense headache, restlessness, delirium, sometimes eclampsia or coma, seem to demand the most energetic treatment, and yet it is surprising to one who has his first experiences with this malady how patients under proper treatment, without the abstraction of blood, emerge from an apparently almost hopeless state and ultimately recover. There may be total unconsciousness, the pupils dilated like rings and insensible to light, the head intensely hot, tonic convulsions present or alternating with frequent clonic convulsions, and yet these symptoms, which in any other disease would be regarded as sufficient to justify the prognosis of certain death, may gradually pass off toward the close of the first or in the second week, and the case afterward progress favorably. In the New York epidemic of 1872, previously to which physicians of this city had no personal experience with cerebro-spinal fever, many cases were pronounced hopeless which ultimately did well without abstraction of blood. In a case occurring in the practice of Dr. Griswold the patient was comatose for three days, with pupils not responding, or but very feebly responding to light, but he recovered without the abstraction of blood, and with the remedies ordinarily employed. In a case which we will presently relate, in speaking of another local treatment, the patient was still insensible in the third week, with pupils greatly dilated and insensible to light, and yet recovered without losing blood. Such cases show that the most urgent symptoms, such as seem to indicate the prompt employment of leeches in order to reduce the meningeal hyperæmia and the consecutive congestion of

the nerve-centres, may be relieved and the patient recover without such depletion, and with the preservation of the blood, which is so much needed in the subsequent asthenic course of the malady.

In only one case have I recommended the abstraction of blood, and this was so instructive that I will briefly relate it: A girl, four years of age, was seized on March 7, 1873, with vomiting, chilliness, and trembling, followed by severe general clonic convulsions lasting about fifteen minutes; was semi-comatose; pulse, 132, and a few hours later, 156; temperature, $101\frac{1}{4}^{\circ}$; respiration, 44; eyes closed, pupils moderately dilated and feebly responsive to light, dusky mottling of skin, constant tremulousness with twitching of limbs. Bromide of potassium was administered in hourly doses of four grains, ice applied to the head and nucha, and a hot mustard foot-bath followed by sinapisms to the nucha. On the following day, March 8th, she was partly conscious, when aroused, but immediately relapsed into sleep, head retracted, bowels constipated; pulse, 136; temperature, 102° ; vomits occasionally. It was thought proper, on account of the extreme stupor, to apply one leech to each temple and the bites trickled slowly nearly five hours. The other treatment was continued. On the 9th the pulse was 180, so feeble that it was counted with difficulty; temperature, $101\frac{1}{2}^{\circ}$. The patient was evidently sinking. It was necessary to order whiskey in teaspoonful doses every two hours, with beef-tea and other most nutritious drinks. Evening, pulse, 172, still feeble. March 10th, pulse, 180, barely perceptible; great hyperæsthesia; axillary temperature, 100° ; axes of eyes directed downward. After this the patient gradually rallied for a time, the pulse becoming stronger and less frequent, but death finally occurred after nine weeks in a state of extreme emaciation and exhaustion. Slight convulsions occurred in the last hours.

It is seen that in the above case, which may be regarded as typical, the patient passed into a state of extreme prostration after the application of the leeches, so that for three days I did not believe that she would live from hour to hour, and death occurred after an illness of nine weeks, apparently from sheer exhaustion. Experience like this, which corresponds with that of most other observers, shows the necessity of preserving the blood and thereby the strength, however urgent the initial symptoms, inasmuch as cerebro-spinal fever in its subsequent course is attended by such marked asthenia. On May 3, 1878, a boy of ten years was admitted into one of our best hospitals, in the service of a prominent New York physician. It was stated that he had been four days sick with cerebro-spinal fever, and among other characteristic symptoms he had had delirium every night and on May 2d delirium in the daytime, which had abated considerably after free epistaxis. In the hospital the application of ten leeches along the spine was ordered, but it does not appear to have diminished the delirium or any other symptom, and on the following day the pulse was so frequent and feeble that active stimulation by brandy was resorted to. He had three severe convulsions on May 13th, which were relieved by ice to the head and nape of neck, and by six minims of Magendie's solution. Severe pains occurred at times in the back and limbs, and on the 29th, one month after the commencement of the disease, the severe pain frequently recurring, twelve leeches were ordered to be applied to the spine. On June 2d the limbs were flexed and quite stiff, and the effort to move them was attended by great pain. The pain in the back was also more constant, and in consequence sixteen leeches were applied to the spine. The next day there was no pain, but the patient was very stupid. On June 6th the records state that he was obviously losing strength day by day, that his emaciation was extreme and his anæmia very marked. But he had great vitality, and although he had strabismus, bed-sores, incontinence of urine and feces, and extreme prostration, he lingered till August 1st. At the autopsy,

"body, a skeleton; brain, dura mater, and pia mater appear normal, except a little thickening of latter at base of brain; ventricles much enlarged and full of clear serum; surface of walls of ventricles looks normal but is soft; spinal cord and membranes appear normal to the naked eye." No disease was discovered in other organs except that the liver appeared congested and the kidneys pale. It can scarcely be doubted that, although some temporary relief from the pain may have resulted to this patient by the repeated application of leeches, which diminished the meningeal hyperæmia, yet his chances for ultimate recovery would have been far better without such depletion. Therefore the histories of cases show that the result of abstraction of blood has been unsatisfactory, on account of the asthenic nature and protracted course of cerebro-spinal fever, and it should be very rarely, if ever, recommended as a remedial agent.

Some benefit is apparently derived from the application of stimulating and moderately irritating lotions along the spine. A liniment consisting of equal parts of camphorated oil and turpentine briskly applied by friction with flannel up and down the spine till redness is produced, appears to cause some alleviation of the suffering and it does not conflict with the use of the ice-bag. Dr. William H. Sutton, of Dallas, Texas, has published the following interesting case, showing the benefit from stimulating and irritant applications over the spine made in an unusual manner. A child, aged three and one-half years, had been three weeks under treatment through error of diagnosis for supposed continued fever. When Dr. Sutton assumed charge of the case on November 20, 1877, the pupils were greatly dilated and insensible to light; features pallid and pinched; pulse, 130; temperature, 103°; patient totally unconscious. November 21st, morning temperature, 105°; pulse, 140; evening temperature, 101½°; pulse, 120. November 22d, morning temperature, 106½°; pulse, 160; restless; evening temperature, 105½°; pulse, 120; had not slept except for a few moments for nearly two weeks. A strip of flannel saturated with turpentine was placed over the spine from the neck to the sacrum, and a hot smoothing iron was run up and down it, and eight drops of the fluid extract of ergot were given every three hours. Dr. Sutton adds: "The father stated to me that as soon as the application was finished the child fell asleep, and slept several hours—the first for two weeks—and the fever rapidly declined. From this time he began to improve and gradually and fully recovered. The use of irritating applications over the spine in the treatment of cerebro-spinal fever has been long and favorably known, but the mode of applying it practised in the above case is novel.

Internal treatment.—It will aid in the selection of the proper remedies to recall to mind the pathological state which we know to be present from the many autopsies which have been recorded. We have seen that the largest mortality, and consequently the most dangerous period, is in the first days, when there is intense suddenly developed inflammatory congestion of the meninges, with more or less secondary hyperæmia of the underlying brain and spinal cord, producing great headache, delirium, or somnolence, with exaggerated reflex irritability of the spinal cord, so that eclampsia is a common and fatal complication.

Fortunately a remedy has been discovered in modern times, the bromide of potassium, which acts promptly and efficiently. It can be safely administered in large and frequent doses to the youngest child. It is quickly eliminated from the system through the kidneys and other excretories in children, so as to prevent the occurrence of bromism, at least to the extent of causing any unpleasant consequences. It causes contraction of the minute vessels of the nervous centres so as to diminish the hyperæmia, as shown by the experiments and observations of Dr. Putnam-Jacobi and others, and at the same time it diminishes, in a marked degree, the reflex

irritability of the spinal cord, two most beneficial and important effects of its use in this disease. Many children by its timely employment are saved from the dangers of eclampsia, and by its sedative effect on the nervous system and contractile action on the capillaries it probably diminishes the intensity of the inflammation and the amount of exudation. I usually prescribe it, as recommended by Dr. Squibb, dissolved in simple cold water. In ordinary cases not attended by eclampsia or marked symptoms which show that eclampsia is threatening, I usually prescribe at my first visit about four grains every two hours to a child of two years, who has the usual restlessness and apparent headache, and six grains to a child of five years. If eclampsia occur, the bromide should be given more frequently, as every five or ten minutes till it ceases. It is important to be able to determine when the quantity of the bromide administered should be diminished, and when its use should be discontinued. I have very rarely observed bromism in children, and never to the extent of doing any serious harm, though for many years I have administered it in large and frequent doses whenever the occasion seemed to require it, but the symptoms of bromism cannot readily be discriminated from those which may result from cerebro-spinal fever such as muscular weakness, dilated pupils, with perhaps impaired vision, unsteady gait, nausea, or vomiting, and abdominal pains. If the case progress favorably, frequent and large doses should, in my opinion, be given only in the first week, after which the doses should be at longer intervals or smaller. But during exacerbations, which are apt to occur from time to time till the patient is well on the way to recovery, the use of the bromide in full doses is again indicated till the urgent symptoms begin to abate.

Ergot is another very important remedy. It is scarcely less useful than the bromide, from its known action in contracting the arterioles and diminishing the flow of arterial blood. The fluid extract, tincture, or wine of *secale cornutum* can be employed, or its active principle ergotine. In this city I think that Squibb's fluid extract has been more used than any other preparation. I have commonly prescribed it except for patients old enough to take ergotine in the pill. The doses employed by different physicians vary greatly. Dr. William A. Thomson, Professor of Materia Medica in the New York University, has prescribed, so far as I am aware, the largest doses in the treatment of this disease, to wit, one teaspoonful of the fluid extract of *secale cornutum* every three hours to a boy of ten years in Roosevelt Hospital in 1878, with apparent benefit as regards the meningeal hyperæmia, although the case was fatal after the lapse of several months from asthenia. The alkaloid ergotine, to which the beneficial effects of the *secale cornutum* are due, may be given in the pill or in solution. In case of much irritability of the stomach it can be employed hypodermically, dissolved in water with glycerine. The efficacy of this agent is most marked during the first and second weeks, when the congestion of the nervous centres is greatest. At a more advanced stage, when there is less congestion and the danger arises from the inflammatory products and structural changes, the time for the use of ergot is passed, or if it is still of some service it is less needed than at first and should be given less frequently.

The severe headache and restlessness which attend many cases, require the occasional use of an opiate, or the hydrate of chloral. The chloral in proper dose never fails to give quiet sleep, and it is supposed by some who have studied its therapeutic action that it diminishes the cerebral circulation. It is therefore an useful adjuvant to the bromide. Five grains usually suffice for a child of six to eight years. The chloral is especially useful in cases attended by eclampsia, or symptoms which threaten eclampsia, since it acts promptly and decidedly in diminishing reflex irritability. Formerly it was considered injudicious and unsafe to prescribe opiates in meningeal inflammation, since it was supposed that

they increased the liability to coma, but experience shows that they are sometimes very useful in this disease when administered in small or moderate doses, and without the risk which was once supposed to be incurred by their use. The thirty-second part of a grain of morphia administered at intervals of some hours was sufficient to relieve the suffering of one of my patients at the age of six years.

Quinia does not seem to exert any marked controlling effect on the course of cerebro-spinal fever or its symptoms, although the paroxysmal character of the severe pains in many patients suggests the use of this agent as an antiperiodic. It was frequently prescribed by New York physicians in the epidemic of 1872, but I believe that the opinion was unanimous that it was not the proper remedy. I have prescribed it in large and small doses, in one instance giving fifteen grains to a child of thirteen years, but do not know that I ever derived benefit from its use in this malady.

When the acute stage has abated, measures designed to remove the serum, which is apt to remain, constituting a hydrocephalus, are indicated. For this purpose the iodide of potassium is probably more useful than any other agent. It is administered by some physicians early, along with the bromide, as they have been in the habit of treating other forms of meningitis. I have prescribed it with the bromide, and alone when the bromide was discontinued, but whether it produces a sorbefacient effect in this disease seems to me doubtful.

The result depends to a great extent on the nursing. The skill of the physician may be thwarted and the life of the patient lost by inefficient nursing. No other disease more urgently requires kind, intelligent, and constant attendance night and day on the part of the nurses. Not only should the medicines and nutriment be given punctually and regularly, but the great restlessness of the patient in the first days requires constant readjusting of the ice-bags, and during the long period of convalescence the utmost care is required to remove at once the excretions in order to prevent bed-sores, and to give the proper amount and kind of nutriment to prevent the emaciation and weakness from which many perish. Among my cases are those who owe their recovery largely to the untiring devotion of mothers. The one that died of bed-sores I have little doubt would have recovered had the nursing been such as some of the others received.

The diet, from the beginning to the end of the malady, should be the most nutritious, and such as is easily digested. It is necessary to give it in the liquid form, unless in mild cases in which the appetite may not be entirely lost. It is proper to aid the digestion by pepsine preparations. Nutritive enemata, consisting of beef-tea, or Leube's extract of beef, milk, and brandy aid in averting the fatal prostration in protracted cases. After the acute stage has passed by and the meningeal hyperæmia has abated, the alcoholic compounds in moderate doses, which in the beginning would be very injurious, may now be useful, administered regularly by the mouth. The room should be dark, well ventilated, and quiet. All sympathizing friends who are not required in the nursing should be excluded. I know no other disease in which this is so necessary, for mental excitement may produce dangerous aggravation of symptoms. Recently a young lady, to whom I made one visit in consultation, and whose recovery seemed probable, was allowed to receive the visit of a young gentleman. Immediately after his departure her headache was intensified, the symptoms became generally aggravated, and the result in a few days fatal.

THE PROPORTION OF MEDICAL PRACTITIONERS TO POPULATION OF DIFFERENT COUNTRIES.—The proportion of medical practitioners in different countries is as follows: France, 2.91 per 10,000; Germany, 3.21 per 10,000; Austria, 3.41 per 10,000; England, 6 per 10,000; Hungary, 6.10 per 10,000; Italy, 6.10 per 10,000; Switzerland, 7.06 per 10,000; United States, 16.24 per 10,000.

WIRING OF FRACTURED PATELLÆ.

By FRASER C. FULLER, M.D.,

LATE HOUSE-SURGEON BELLEVUE HOSPITAL, NEW YORK.

THE following cases were operated upon by me in Bellevue Hospital during the visiting service of Dr. Charles McBurney, and my obligations are due to him for his kindness in deputing to me the treatment of cases during his absence from the city on summer vacation, it being during this time that these cases entered his wards.

I am prompted to report them thus early in their history, and during the convalescence of one case, as the reading of Mr. Lister's paper at the meeting of the Medical Society of London on October 27th has excited an active discussion in that city, evidencing wide differences of opinion as to the propriety of the operation in certain cases.

It gives me great pleasure, then, to have this opportunity to report three successful cases; firstly, as evidence of the success of the operation in securing bony union of the fragments; and, secondly, as to the dependence of success upon antiseptic methods, the laying open of a knee-joint presenting the best of opportunities for testing the value of one special form of operating.

As the details of the operation have differed somewhat in my cases from those described by Mr. Lister in his paper (*vide Lancet*, November 3d), I will, for brevity's sake, omit a formal description of the operation and include it in the history of the cases.

CASE 1. *Compound comminuted fracture of left patella.*—Alex. C—, aged forty-five, contractor's foreman, entered Ward 8, July 22d, 11 P.M. About two hours before, when under the influence of liquor, he fell from the second story of a building, striking his knee on an iron grating covering a coal chute. On entrance patient still alcoholic. Examination revealed a compound comminuted fracture of the patella. The wound was on the front of the joint, directed downward and outward, somewhat ragged, and one and one-half inch in its long diameter. A temporary dressing of iodoform and bichloride of mercury was applied for the night; a posterior splint and an ice-cap.

On the following day, Dr. McBurney being engaged in a private operation, he directed me to attend to the case. The operation was performed under almost constant irrigation with bichloride of mercury—one part to two thousand; the limb having been previously prepared by shaving, washing with soap and water and the bichloride solution, and the arrangement of wet towels about it having been made, the extremities of the wound were extended, the incision then being oblique to the axis of the limb. The capsule was found only moderately lacerated. This moderate degree of laceration I believe to be the case in fractures due to direct violence. The lower half of the patella was found badly comminuted, and the fragments so loosely attached to the periosteum that it was necessary to remove all but two pieces. The larger of the two was about the size of an ordinary chestnut, the smaller half that size. The patella now consisted of three pieces, the upper fragment comprising a little more than one-half the bone. With a common bradawl I then drilled one channel in the upper fragment, the drill passing obliquely down to, but not through, the articular cartilage. A corresponding channel was bored in the larger of the two lower fragments, and they were brought together with a suture of silver wire. The hospital wire was so fine and brittle that I was obliged to use it double. The smaller lower fragment I found was best kept in position by suturing it to the larger lower fragment. For this I used a large violin string, which I had prepared and made aseptic after Kocher's method. The next step was to wash out the joint, which I thoroughly did through a Nélaton catheter, using the bichloride solution. Mr. Lister does not mention this step in his description of his operation, and I am told

that he does omit it, but it seems to me that freeing a joint of blood clots and bloody serum renders it purer than it would be if they were permitted to remain in.

Next the insertion of the drainage-tubes and the suturing of the capsule occupied my attention. The wound in the capsule was about an inch in length on either side of the patella, and I was satisfied to place a drainage-tube at each extremity of the wound, believing that with the subsequent elevation of the foot the tubes would be at nearly the most dependent portion of the joint. The tubes were of rubber, medium size, and their inner ends were just within the capsule, not more. I then, with cat-gut, sutured the capsule, finding no difficulty in taking it up laterally to the patella, and in front of the bone where it is continuous with the periosteum it can be sewed with little trouble. This suturing of the capsule I regard as a very important procedure. Mr. Lister omits it in his description of his operation, and, I believe, also in his practice; but to my mind it is one of the most important steps in the operation. If the capsule is well sutured the joint is practically closed and shut, and what serum exudes or synovia forms, drains through the tubes into the dressing, and not into the loose cellular tissue between the capsule and the skin, where it must drain if the capsule is not sutured. Again, with the capsule sutured it heals independently of the skin, lessening the danger of an adherent cicatrix. Moreover, the soft tissues in front of the joint must be thicker and stronger with a sutured capsule than without it.

The ragged edges of the skin were trimmed and then united with cat-gut. Three short drains leading into the areolar tissue between the capsule and the integument were employed. I neglected to mention that the disposition I made of the twisted ends of the wires was to turn them down between the fractured surfaces. I think this preferable to hammering them into the anterior face of the patella. Of course it is intended that the wire should remain permanently in the bone. When drawn tightly, and the ends disposed of as above, it becomes embedded in the bone, and I have never heard of it causing trouble either in patellæ or in long bones where I have employed it in resections. If the wire is employed for a temporary purpose, complete healing of the skin is delayed, and its removal is not always an easy matter. A final washing-out of the joint through the tubes was made, the fluid running through clean and clear. The tube ends and the wound were well dusted with iodoform, protectives applied, more iodoform, then moist bichloride gauze to act as the absorbent part of the dressing. Then a thick boracic acid cotton dressing, an evenly compressing bandage, and the wound dressing was complete. I should have mentioned that all vessels were ligated, as cut, with cat-gut, and the wound was perfectly dry in a vascular sense when closed. An anterior plaster-of-Paris splint was applied, reinforced with a wire-gauze frame. Patient put to bed and the leg suspended at an angle of 45°. No special after-treatment was employed. Patient's temperature never went above 100°, and after the fourth day it was normal.

August 7th.—Fifteen days after the operation, the dressings were changed to remove the tubes. Primary union of the skin had taken place. The joint looked normal.

August 17th.—Again dressed, and the sinuses formed by the tubes were found closed.

August 24th.—Splint removed and patient allowed to move the leg as much as he felt inclined. Motion was gradually established, and October 15th patient was discharged.

No passive motion had been employed, and he could flex his leg to a right angle with the thigh, and there was no doubt but that there was bony union. One leg was as good as the other.

CASE II. *Simple fracture of left patella, due to muscular action; wide laceration of the capsule.*—James S—, aged twenty-three, watchman, entered Ward 10,

September 6th. The history pointed directly to a fracture from muscular violence. Up to the day of the operation patient was treated on a posterior splint, with foot elevated and an ice-cap over the joint.

September 24th.—The inflammation having nearly subsided I proceeded to wire his patella. A transverse incision about one and half inch in length was first made, and either extremity of it extended until the incision in the skin corresponded to the rent in the capsule. This was nearly four inches in length. I would digress from the description of the case to discuss the relative merits of the vertical and the transverse incision. In this case especially, and in the two others to a greater or less extent, a vertical incision would not have permitted me to examine the torn capsule, or the joint, or the fractured bone as I desired to. Mr. Lister and the other gentlemen in Great Britain who have done this operation all employ the vertical incision, and it is noticeable that they omit to say anything about the capsule. If the capsule is disregarded the vertical incision is all sufficient for purposes of wiring the bone, and leaves a smaller and perhaps a better situated scar than does the transverse incision; but to my mind the capsule is all important, and the incision through the skin should be made to facilitate getting at it for the purpose of suturing it. In a fracture due to direct violence, be it simple or compound, the vertical incision may be sufficient, for in such a case the rupture of the capsule is insignificant; but in a fracture from muscular violence the transverse incision will be necessary, as the capsule in that class of cases is widely ruptured. To return to Case II., the direction of the fracture was transverse, and exactly through the middle of the bone. The separation of the fragments was about an inch. Fringes of aponeurotic and fascial structure hung down between the fragments, and on each fractured surface was a blood clot so hard and tenacious that it could only be detached by means of a sharp spoon. Underlying this was healthy bleeding bone. The joint contained blood clots and bloody serum. It was washed out as in the first case. Two wires were employed, the fragments accurately adjusted, and the wire ends thrust down between the fractured surfaces. The edges of the capsule were trimmed, sutured with one line of catgut, the skin with a second. A similar arrangement of tubes as in the first case; dressing the same.

This patient's highest temperature was 100.5°. Dressing changed and tubes removed on the eleventh day. A narrow line of the sutured integument had sloughed, probably due to pressure over the patella from the dressing, but a few skin grafts rapidly closed the ulcer. At the end of seven weeks patient was allowed to walk about the ward, the joint being kept stiff by light pasteboard splints. At the end of the eighth week motion commenced, and November 29th patient was discharged with 30° flexion, increasing every day from simply walking upon his leg. Patient is a professional base-ball player, and now runs well, feeling his leg to be as strong as ever.

CASE III. *Simple fracture of left patella from muscular action.*—C. R—, aged twenty-four, driver, entered Ward 10, October 9th. Operated upon twenty-four hours after injury. It was with some trepidation that I operated in this case so soon after the injury; but I looked upon it as a radical way to relieve the inflammation then commencing in the joint, and that it was successful is proven by the fact that when I removed the dressing at the expiration of twelve days, the circumference of the joint was four inches less than when the dressing was applied. In this case the lower fragment was very small and tilted, so that the broken surfaces were greatly at variance with each other. This class of cases, although not so pleasing to operate upon, are surely the most appropriate, as it is difficult to imagine a good result accruing from any treatment that would not direct the fractured surfaces in a measure toward each other. Treated in the ordinary way it is impossible to do this, the lower fragment being so small that one is unable to

obtain any purchase upon it. Two wires were introduced, and a mortise cut in the upper fragment to partly contain the lower, good apposition being obtained. The rupture in the capsule in this case was at least three inches, and was treated similarly to the others. As stated above, the case was dressed on the thirteenth day. Primary union of the skin was perfect. His temperature was once 101° , at all other times not above 99.5° . Patient allowed to walk about ward with knee kept stiff by splints at seventh week, and to-day, December 5th, they have been removed, and he is allowed to commence motion himself. There is no doubt but that he has good bony union.

The secret of success in these cases, and I think the remark is applicable to all surgery, instances of pure luck being excepted, is antiseptic surgery in the true sense of the term, and in detail especially. The reading of Mr. Lister's paper at the meeting of the London Medical Society, October 29th, immediately excited an active interest in the operation. The discussion of the paper by the society, November 5th (vide *Lancet*, November 10th), brought forward opinions from many surgeons for and against the operation. It is gratifying to notice, however, that those gentlemen who advocated the operation are those who practise antiseptic surgery. The unbelievers have not yet been converted. In *The Lancet* for November 17th appears a report by Dr. Wm. McEwen of four cases, all successful.

At the meeting of the London Clinical Society, November 9th (vide *Lancet*, November 17th), Mr. G. R. Turner presented a table of fifty cases, this table not including cases operated upon in his country. Of the fifty cases there were two deaths. In the same number of *The Lancet* is a fatal case published, occurring in the practice of Mr. John Wood. Antiseptic precautions are claimed to have been employed, yet a horse-hair drain appears to me to be insufficient for the purpose of drainage from a knee-joint. The reporter refers to the joint as being very tense at subsequent dressings. For the same reason I prefer a rubber to a bone drain, on account of the danger of the capsule cutting the tube or collapsing it.

Regarding the results from the old treatment of fractured patella, I do not consider them satisfactory. Many cases recover with fairly good function, but as many go about with weak, unreliable joints; and, whether it has been my particular experience to meet them, I have seen many examples of refracture of the bone, fracture of the opposite patella, rupture of the ligament, and other injuries resulting from falls due to an unreliable limb. Regarding the results following wiring, I believe bony union to be the rule, especially in recent fractures, otherwise a very close ligamentous union. Regarding the danger of the operation, and it should be the first consideration, I conscientiously believe it to be fractional, if the case is treated thoroughly antiseptically. It is proper, however, that I should leave the discussion of the ethics of the operation to such a man as Mr. Lister, and they are to be found fully analyzed in his most interesting paper.

SULPHATE OF SODA may be advantageously substituted for sulphate of magnesia. According to Fothergill, the soda salt acts on the liver, while the magnesia salt acts on the intestinal glands. It has the disadvantage of a more nauseous taste than the common salts. Dr. T. Curtis Smith, of Aurora, Ind., in the *Medical and Surgical Reporter*, recommends the following method of disguising the taste. Put a half ounce or an ounce of the powdered sulphate of soda in a gill of hot water, add to this twenty to thirty drops of arom. sul. acid. and an ounce or two of sugar. This is easily taken. This should be taken fasting—generally just after rising in the morning. It is useful whenever a cholagogue saline, so to speak, is indicated. Dr. Smith finds it useful in acute articular rheumatism occurring in plethoric subjects.—*Medical World*.

THE CURE OF URETHRAL STRICTURE IN ONE SITTING.

BY GEORGE M. SCHWEIG, M.D.,

NEW YORK.

WHEN, some years ago,¹ I published a description of a new stricture-dilator, I laid claim to nothing further than furnishing the profession an instrument which, for certain recognized and established purposes, was superior to any other then known. I was, at the time, myself unaware of the possibilities of the method when carried out in a more perfect manner than it had been with the instruments previously in use. It is only within the last year or two that clinical experience has taught me the facts that justify the title of this monograph. Be it understood, moreover, that the claim implied by that title is by no means intended to be universal. But while I freely admit that many cases of urethral stricture present collateral conditions that render it either difficult or inadvisable to pursue such a course, yet a very respectable majority admit of permanent removal at a single sitting without any appreciable risk of harm or injury.

Prior to the introduction of my instrument, "divulsion," or "forcible expansion," was a term synonymous with violence and more or less traumatism, accompanied frequently by very disagreeable accidents or sequelæ, such as shock, hemorrhage, laceration of mucous membrane, urethral fever, etc., and was always a painful operation. The results, moreover, were not such as to compensate for the attendant risks. As the lesser of two evils internal urethrotomy became gradually more popular. Those who have frequently practised this last, however, will admit that a mode of treatment which is painful, accompanied by hemorrhage, often of so alarming a nature as to tax the utmost skill of the surgeon to check; that, as a rule, confines the patient to bed for some days, confessedly requires more or less after-treatment, and withal shows a certain percentage of relapses, does not present a very acceptable substitute for even the crude divulsion of former days. My experience for the last five years (I have used my instrument since 1878) has only the more firmly convinced me of the truth of the statement made in the paper above referred to, that "dilatation carried to a *sufficient extent* is not only the *safest* method of treating the great bulk of cases of organic stricture, but the one which is at the same time the most likely to secure *radical and permanent results*."

In THE MEDICAL RECORD of August 2, 1879, I published a paper entitled "The Treatment of Urethral Stricture by Slow Divulsion." I am free to admit that I have almost entirely abandoned *slow* divulsion. If I had recourse to it at first it was for lack of boldness. It was because the experience with divulsion of others bade me be cautious. As I treated case after case, however, without any of the dreaded accidents occurring, I became gradually less conservative, until I was finally brought to realize that, performed with a proper instrument, rapid divulsion is as harmless a proceeding as passing a sound.

Now as to results. These are, so far as I have been able to judge, absolute, perfect, and permanent. I will not say that I have never failed. I did fail in one case last summer. It was that of a gentleman with an exceptionally large urethra. The largest instrument I possessed at the time dilated to 40 only. His natural meatus was 36. Urethral calibre a trifle above that. By dilating to 40 I did not obtain a *sufficient* degree of over-distention; hence the failure. The patient was anxious to leave town, and I had no time to get a specially large instrument made for him. I performed internal urethrotomy with Otis' instrument, obtaining at the time a urethra with a minimum calibre throughout of 36. The patient left for the West shortly after the operation. He returned a few weeks later for a stay of only a few days prior to his departure for Europe. There had

¹ MEDICAL RECORD, May 3, 1879.

then been some recontraction, although not much, at the site of the stricture. He wrote to me not long since to the effect that a slight urethral discharge that he had had right along still continues. I have no doubt that had I possessed at the time an instrument dilating to 44, the result would in this case have been as satisfactory as it was in all my others.

The one fixed rule to go by is to dilate to a *sufficient extent*. When it is borne in mind that the object is to destroy the continuity, or at least the resiliency of the stricture-fibres, it becomes obvious that to accomplish such a result with certainty the expansion must go, to some extent, *beyond* the normal urethral calibre; yet, if confined within proper limits, the distensible urethral walls will remain intact, and the traumatism be submucous, and limited to the unyielding stricture tissue.

I have dispensed with after-treatment altogether. An occasional bulb or sound for the purpose of observation within the first year completes the attendance, and even this I have thus far found superfluous. I will give a few aphoristic cases from private practice by way of illustration.

CASE I.—A. S.—, traveller, about thirty years of age. Saw him first January 5, 1882. Stricture in penile portion. Would not admit large dilator. Introduced small dilator and stretched to 32. January 7th, introduced large dilator. Stretched to 40. January 20th, passed a 28 sound (full size of meatus). Saw him again May 5th; passed 28 bulb; all clear.

CASE II.—Mr. S.—, collector, twenty-seven years of age. First examination August 18, 1882. Had gonorrhoea three years prior to that. Contracted meatus. Urethral discharge. Urethra unevenly strictured at from 4 to 6 inches. After some preparatory treatment, cut meatus and dilated strictures to 40, on September 17, Dr. Henry Herman assisting. Passed 33 sound after operation. Passed sound and 30 bulb several times by way of observation until November 1st. All remained well and discharge had ceased. I saw him recently. He had married, and had felt none of his former symptoms.

CASE III.—J. J.—, letter-carrier, twenty-seven years of age. Seen first November 9, 1882. Strictures at 2½, 5½, and 6½ inches, the two anterior ones exceptionally hard, unyielding, and resilient. After some preparatory treatment I introduced dilator on December 31st; dilated to 40. On account of the large amount of residual callus I gave him some after-treatment, consisting of sounds and electrolysis, to produce absorption. There was never any further obstruction. March 11, 1883, callus had wellnigh disappeared. April 1st, passed bulb 26, which came back unchallenged.

CASE IV.—R. M.—, merchant, thirty-five years of age. Had gonorrhoea seven years ago. First examination January 1, 1883. Found well-marked stricture at 4½ inches. By passing sounds of increasing size in rapid succession, I made way for dilator, and at once stretched to 40. January 6th, passed 27 sound. January 27th, passed 29 sound; slipped in easy. He called next July 17th, when on examination I found all as I had left it.

CASE V.—C. H.—, cattle-dealer, twenty-eight years of age. Called February 21, 1883. Found multiple stricture at from 5½ to 6½ inches, also contracted meatus. Next day, February 22d, cut meatus. March 5th, stretched strictured portion to 40. There was no after-treatment whatever. He left at once for his home in Montana. From late advices he remained well.

CASE VI.—E. D.—, salesman, thirty-five years of age. Examined July 2, 1883. Stricture extending from 5 to 5½ inches. July 3d, passed small dilator, stricture being too close to admit large one. Stretched to 32. July 5th, stretched to 40. July 6th, passed 28 sound (full size of meatus). Did not see him again until the beginning of November. Passed 26 bulb. All clear.

CASE VII.—F. B.—, merchant, fifty-five years of age.

Called August 23, 1883, accompanied by his family physician, Dr. F.—. Found contracted meatus, imperfect phimosis, and strictures at 1½ and 5½ inches. September 18th, operated for phimosis and cut meatus. Strictures being close, especially the posterior one, dilated with sounds at intervals of several days until wide enough to admit large dilator. October 12th, dilated anterior stricture to 38. October 20th, dilated posterior stricture to 40. October 30th, passed 31 sound. November 11th, passed 30 bulb and 31 sound. No recontraction.

CASE VIII.—H. W.—, merchant, twenty-seven years of age, from western part of New York State. Called August 26, 1883. Found stricture at 5½ and 6½ inches. Dilated at once to 40. Passed 30 sound (full size of meatus) August 27th, and again August 28th. He then left for home. Returned October 28th; passed bulb 26 and 30 sound. All clear. Called again November 25th. A like examination showed not the slightest recontraction.

CASE IX.—Mr. R.—, aged fifty-eight, from Albany, called September 22, 1883, accompanied by Dr. B.— of Brooklyn. Found stricture at 5½ and 6½ inches. Urethra highly hyperæsthetic. Put him on sedative treatment. He left for home and returned October 27th, again accompanied by Dr. B.—. I then dilated to 40, followed with a 35 sound, which slipped to bladder by its own weight. He left at once for home. Came down again November 24th, no instrument having been passed meantime. Passed 33 sound, which slipped in without the slightest halt. There was no sign of a recontraction.

Now I am well aware that most, if not all, of the above cases are of too recent a date to warrant permanence of results. I give them merely to illustrate the feasibility of rapid divulsion with perfect safety. Still, I think I may justly expect *at least* as good results from them as have been obtained from those where *slow* divulsion has been practised; and as of this latter class I have had cases under observation for about five years without any relapse, I shall continue to believe, until I have evidence to the contrary, that the results obtained in the cases given are permanent. I may add here that not one of my stricture patients has been confined to bed for a single hour as the result of this treatment, and that not a single undesirable accident has occurred.

It may not be out of place here to say a word concerning the electrolytic treatment of stricture, more especially in that I have been quoted as a *quasi*-advocate of that method. I employ electrolysis for the removal of residual callus in persons of advanced years, or others where spontaneous absorption does not go on readily. As for galvanism removing or curing a stricture—while I do not desire to deny possibilities—I confess I have never had the patience to see a case through. At any rate, even if feasible in favorable cases, it would be taking a long, tedious, roundabout way to accomplish what can be obtained with infinitely more speed and certainty, and with less discomfort, by a short cut.

157 EAST FIFTY-FIFTH STREET.

AMERICAN *versus* ENGLISH DENTAL EDUCATION.—The President of the American Dental Society of Europe, at their meeting at Cologne in August, made the following remarks during a discussion on the causes of failure of gold as a filling material: "I am an examiner at one of the dental hospitals in London, and I have been surprised and pleased to remark the excellence of the operations made by the students. The skill in operating is accompanied, as you all know, by a most thorough theoretical knowledge. I have myself passed seven different medical examinations. The easiest of these was that for M.D. at the University of New York. My subsequent examinations for D.D.S. at the Philadelphia Dental College amounted to absolutely nothing; and I am convinced that the English system of education, combining, as it does, thoroughness both in theory and practice, must in the long run triumph over the American system."

THE MILD WINTER CLIMATE OF NEWPORT, R. I., AS THE EFFECT OF THE GULF STREAM.¹

By H. R. STORER, M.D.,

PRESIDENT OF THE NEWPORT MEDICAL SOCIETY.

SEVERAL months ago I had somewhat to say in the *Sanitarian*,² and subsequently in the *Boston Medical and Surgical Journal*,³ concerning the fitness of Newport for the residence during winter of delicate people and convalescents, who desired to avoid the inclemency and extreme changes of temperature of the main land at that season, and who did not care to have the fatigue, expense, uncertainty of comfort, and distance from home friends, of the journey to Florida, Bermuda, or the West Indies. The facts that I presented upon evidence, from personal and other medical testimony, and from meteorological and mortuary statistics, could not be gainsaid; the only criticism that was attempted having been to the effect that, however valid the facts, they conflicted with another person's preconceived theory. Since the dates of my previous communications, additional proof has been given by Mr. Ernest Ingersoll, of the very direct effect upon the Newport waters, and therefore upon its climate of the neighboring Gulf Stream, and to cite this may interest the readers of THE MEDICAL RECORD.

In speaking hitherto of the general effect of the gulf stream in this connection, I might have quoted the following, by Lorin Blodget, of Philadelphia: "Climates distinctly maritime, or directly controlled by adjacent water surfaces, exist in but few positions on the eastern borders of the continent. At Norfolk, Newport, Nova Scotia, and Newfoundland on the Atlantic coast, there are quite decisive maritime influences, particularly at or near Newport, and over most of the Nova Scotian peninsula; but these are due to unusual exposure and close proximity to the Gulf Stream."⁴

In one of my former papers I alluded to the absolute difference in the temperature of the sea-water north and south of Cape Cod, produced by the outward projecting of that promontory as an abrupt dividing line between the eastward flowing Gulf Stream and the inner and westward arctic current, and to the evidence of this afforded by the distinctly northern and southern character of the marine floræ and faunæ of these portions of the Atlantic coast. This fact seems first to have been intimated, in a general way, in reference to the geographical distribution of our coast-fishes, by my father in 1839, nearly fifty years ago.⁵ A dozen years later, in 1852, Professor Harvey, of Dublin, in describing the sea-weeds of North America, indicated the following as the "regions of algæ into which the eastern and southern shores of the North American States may be divided:

"First.—Coast north of Cape Cod, extending probably to Greenland.

"Second.—Long Island Sound to the sands of New Jersey.

"Third.—Cape Hatteras to Cape Florida.

"Fourth.—The Florida keys and shores of the Mexican Gulf."

Of the first region, including Massachusetts Bay, "all the species," he said, "are arctic forms, confined in the European waters to very high latitudes, and all appear to vegetate nearly as far south as Cape Cod, to which limits they are almost all confined. The marine flora of this region as a whole bears a resemblance to that of the shores of Iceland, Norway, Scotland, and the north and northwest of Ireland." Of the second region, that of the neighborhood of Newport, "in comparing its plants with those of the first, a very marked difference is at once seen. We lose the arctic forms whose place is sup-

plied by sargassum¹ (one species of which is the distinctive weed of the Gulf Stream), etc." Of the third region, some of whose forms are "tropical," "many of the species found within these limits are common to the second region."²

Twenty and twenty-seven years later, in 1872 and 1879, Professor Farlow, of Harvard University, was still more explicit in his statements. "As long ago as 1852," he said, and this I have already quoted, "when the first volume of the 'Nereis Boreali-Americana' appeared, it was understood, in a general way, that Cape Cod was the dividing line between the northern and southern marine ora. The question has since been raised whether Cape Cod is as strictly the dividing line as Harvey had supposed; whether northern species do not occur at exposed southern points, as Gay Head and Montauk, and southern species wander northward to Cape Ann. Most decidedly, I think, such is not the case. None of the characteristic algæ of the north, with a solitary exception, are found south of Cape Cod."³ To the above I might have added also from Professor Farlow, in a subsequent year, the following: "Cape Cod is the dividing limit between a marked northern and a southern flora. In fact the difference between the floræ of Massachusetts' and Buzzard's Bays, which are only a few miles apart, is greater than the difference between those of Massachusetts Bay and the Bay of Fundy, or between those of Nantucket and Norfolk. This difference in the flora corresponds precisely with what is known of the fauna. That Cape Cod formed a dividing line was known to Harvey, and subsequent observation has only shown, on the one hand, that the floræ north of Cape Cod is more decidedly arctic than he supposed, and that, on the other hand, south of the Cape it is more decidedly that of warm seas."⁴ That most of the more than one hundred species of sea-weed or algæ collected for the United States Fish Commission by Professor Farlow in the vicinity of Newport are southern or subtropical as compared with those of Massachusetts Bay, and almost none of them northern, shows that the difference in the temperature of the waters north and south of Cape Cod must, as has been said, be absolute. This difference must necessarily be a permanent one, and comparatively very nearly as decided during winter as in summer.

Of interest in this connection is the apparently accepted fact that the cold Labrador southward or shore current is less marked in winter than in summer, or descends beneath the surface during that season at a higher latitude, so that during winter the Gulf Stream itself is thus permitted a more northerly set, and its inner margin comes nearer than to the Rhode Island coast. This question is discussed at length, and charts are given of the summer (July) and winter (January) direction of the currents, by Petermann, of Gotha, in his very elaborate paper upon the Gulf Stream, and thermometrical knowledge of the Atlantic Ocean.⁵

It may be well, such is the great importance of this subject, not merely to students of the natural history of open sea, and to climatologists, but to all practising physicians, having as they do frequently to consider what are the most favorable localities for them to utilize for general and special purposes in the treatment of their patients, to present Professor Farlow's evidence as to the two floral regions above mentioned in even greater detail. "If we regard," he says, "the marine vegetation of the northeastern coast of the United States as a whole, we see that, beginning at Eastport, we have a strongly marked arctic flora, which is a direct continuation of that of Greenland and Newfoundland. As we proceed

southward toward Boston, although the luxuriance of growth is less, the general appearance of the flora is still unmistakably arctic, if we except a few sheltered localities. As soon as we pass to the south of Cape Cod, however, the flora assumes an entirely different aspect. The Arctic and Northern European forms have disappeared, except at a few exposed points, and in their place we find a number of species characteristic of warmer seas." "The general fact," he continues, "of the distinctness of the two floræ is not weakened by the knowledge that we now possess, owing to the investigations of the Fish Commission, of the existence in a few sheltered localities north of Cape Cod of some of the characteristic species of Long Island Sound, and in a few exposed spots south of the Cape of northern species." And again, "the marine flora of Southern New England is much like that of the Mediterranean."²

What has been stated by Professors Harvey and Farlow of the marine flora of the vicinity of Newport, has been shown to be also true of its marine fauna. Professor Verrill, of Yale College, has particularly referred to this in his "General Remarks upon the Habits and Distribution of the Invertebrate Animals of Southern New England Waters." "In prosecuting our explorations (for the United States Fish Commission)," he said, "we soon found that there are in the waters of this region quite distinct assemblages of animal life, which are dependent upon and limited by definite physical conditions of the waters which they inhabit." The first of these regions is that of the bays and sounds "along the coast from Cape Cod westward and southward," at the mouth of one of which Newport is situated. "These shallow waters consist of nearly pure sea-water which has a relatively high temperature, for it is warmed up both by the direct heat of the sun and by water coming directly from the Gulf Stream, and bringing not only its heat but also its peculiar pelagic animals. Owing to this influence of the Gulf Stream, these waters never become very cold in winter, for some of the small, shallow harbors never freeze over. The greater part of the animals inhabiting these bays and sounds are southern forms."³

In his recent article upon Professor Alexander Agassiz' laboratory or aquarium for research at Newport, in the September number of *The Century* magazine, Mr. Ingersoll corroborates Professor Verrill, and is even more distinct in his language. "There is found," he says, "to be a startling difference in the oceanic fauna north and south of Cape Cod. The bather who has tried the surf at Nahant and then at Newport needs no thermometer to understand the immense contrast of temperature between the two coasts. The reason is plain: into Massachusetts Bay pours the icy flood from Labrador and the berg-haunted Banks of Newfoundland, while the south shore is washed by the great tepid current from the tropics, which the Cape swerves off until it strikes straight out to sea to warm the Irish coast. North of Cape Cod one picks up on the beaches and dredges from the bottom of the bay few sea-animals (at least of invertebrates) except those of arctic habit, and these grow more abundant as he proceeds northward; while he misses dozens and dozens of species that he knows may be collected merely by crossing the narrow peninsula which has stood for ages in some shape, a barrier to the southward extension of northern forms, and to the northward travel of those animals whose home is in the southern seas."⁴ And again: "This particular locality (Newport) is highly favorable to the study of marine zoölogy, because the jutting headlands on each side of the harbor make a funnel into which, twice a day, the entrapped tide drives the pure ocean waters fresh from the warm path of the

Gulf Stream, bringing a harvest of living things that elsewhere along the coast remain far outside. Mr. Agassiz is therefore able to get, at the very door of his laboratory, a large series of thoroughly pelagic animals, which other naturalists (at least everywhere north of Hatteras) must go far afloat for, and would regard as wholly extra-littoral."¹

Now, to those who may claim, however unreasonably, that the researches of Professor Agassiz and those of Professor Verrill have thus far been confined to summer types and species, and that the lower marine fauna of Newport, even to the molluscs, echinoderms, annelids, and sponges, may, like the higher forms, seals, porpoises, sea-turtles, and fishes, be but migratory in their character, and disappear as winter draws on—although, in point of fact, some of these vertebrates appear in greater number during this very season—it may be replied that the criticism cannot be true of a great many of the marine invertebrates studied by Professors Verrill and Agassiz, nor of that very large portion of the sea-weeds and mosses constituting the marine flora, which remain permanently attached to the rocks of their birth, and indeed are, some of them, in full fructification during the winter months. Since they are southern species, they would of course be destroyed were the water very materially chilled at any season of the year. It is well known that Newport's outer harbor and the mouth of Narragansett Bay are seldom or never frozen, even close along the shore. If, accordingly, the water thus keeps moderately warm, the atmosphere in contact with it must necessarily be favorably affected to a corresponding extent, and even if we grant that from the thermometric condition of the neighboring coast, and of the slightly brackish water of upper Narragansett Bay, twenty and thirty miles away, at Fall River and Providence, there is a tendency, during certain winds and at ebb-tide, to chill the waters of the lower Bay, it must not be forgotten that each incoming tide brings in a fresh supply of warmth from the never-failing source close at hand, the inward sweeping curve of the Gulf Stream, before it is deflected eastward by Cape Cod.

That the average winter climate of Newport is a very mild one, has long been known. That the temperature of its atmosphere during winter is raised through the warmth of its surrounding sea, has become a matter of evident demonstration. That its climate, in the truest sense, is to be called oceanic, can therefore no longer be denied.

From the meteorological data collected by the late Professor Henry, of the Smithsonian Institution, I have prepared the following tables. In each instance, it will be noticed, the evidence is from Government observers, whose instruments and methods of observation were presumably identical. The comparisons of the winter climate of Newport, with those of Boston, New York, and Philadelphia, are therefore the more reliable.

I. MEAN YEARLY TEMPERATURE. (Isothermal.)—The curve for Philadelphia passes near Sandy Hook, south of and parallel with Long Island.

Boston (Fort Independence, Castle Island), 48.76°, 26 years, during 1824-70.

Newport (Fort Adams), 50.14°, 19 years, during 1842-70.

New York (Fort Columbus, Governor's Island), 51.82°, 48 years, during 1821-70.

Philadelphia (U. S. Naval Hospital), 52.25°, 8 years, during 1843-69.

II. MEAN SUMMER TEMPERATURE. (Isothermal.)—The curve for Philadelphia passes to the ocean near Atlantic City.

Boston..... 68.47° | *New York*..... 72.64°
Newport..... 69.90° | *Philadelphia*..... 72.44°

III. MEAN WINTER TEMPERATURE. (Isocheimal.)—

¹ *Ibid.*, page 731.

¹ Loc. cit.: *The Marine Algae of New England*, pages 3, 4.

² Loc. cit.: *List of the Seaweeds, etc., of the South Coast of New England*, page 282.

³ Report upon the Invertebrate Animals of Vineyard Sound and the Adjacent Waters, etc. Report U. S. Fish Commission, pages 298, 299. Washington, 1873.

⁴ Ernest Ingersoll: *Professor Agassiz' Laboratory*. *The Century*, September, 1883, page 728.

The curve for Philadelphia passes near Sandy Hook and the eastern extremity of Long Island, close to Newport, and by the elbow of Cape Cod.

Boston.....	28.60°	New York.....	31.30°
Newport.....	31.46°	Philadelphia.....	32.25°

IV. WINTER MONTHLY AVERAGES.—

	December.	January.	February.
Boston.....	31.24°	26.85°	27.72°
Newport.....	33.63°	30.23°	30.53°
New York.....	33.50°	29.87°	30.53°
Philadelphia.....	33.26°	30.79°	32.71°

From the above it will be perceived: *First*.—That the difference in mean winter temperature between Boston and Newport, 2.86°, is nearly four times greater than that between Newport and Philadelphia, which is 0.79°; and that the mean winter temperature of Newport is 0.16° warmer than that of New York.

Second.—That while there is a difference of 2.39° in the monthly average for December, between Boston and Newport, in favor of the latter, Newport is during that month warmer by 0.13° than New York, and 0.37°, an even larger fraction, warmer than Philadelphia.

Third.—That the difference in the monthly average for January, between Boston and Newport, 3.38°, is six times greater than that between Newport and Philadelphia, and that during this month Newport continues warmer than New York by 0.36°, a third of a degree.

Fourth.—That in February, the coldest month of the year in a great many places, the monthly average for Newport is higher than during January; that it is now precisely the same as that of New York for this month; and that the difference between the averages for Boston and Newport for February, 2.81°, is greater by nearly a degree (0.63°) than that between those for Newport and Philadelphia, 2.18°, although the latter of these places has already begun to feel the influence of approaching spring.

Fifth.—In other words, that while the isothermal, like the isothermal line of Philadelphia, passes to the southward of Newport, their isothermal or winter curves but slightly vary.

In view of the above, and the peculiar equability and "softness" of the Newport climate, of which I have elsewhere given evidence, it is not perhaps too much for me again to claim that Newport is better adapted, all things considered, than any other point upon the northern coast, and perhaps than any other in the Northern States or Canada, for the residence of delicate persons and invalids during fall and winter, as can easily be determined for himself by any physician who will take the trouble to visit the place at those seasons, or to put himself in correspondence with any of the following members of the Newport Medical Society: Drs. Francis, Rankin, Rives, Barker, J. P. and P. F. Curley, News, Sears, Wheeler, Goddard, Angell, Hurley, Dyer, Mason, Powell, and Fisher; or with Drs. Turner, Engs, Odell, Birkhead, and Brackett, also of Newport, or Drs. Argyle Watson and W. D. McKim, now of New York City. As to the advisability of Newport for invalids at other seasons of the year, evidence will doubtless willingly be given by Drs. Marion Sims, E. S. F. Arnold, Cleveland, Roosa, J. C. Peters, Beverley Robinson, Weir Mitchell, Stearns, and many other New York, Philadelphia, and Southern and Western physicians who have had personal experience of its curative effects. To Dr. Sims is undoubtedly due the credit of having commenced the sanitary agitation at Newport, which has given the city a better water supply, and will soon result in perfected sewerage, and a general conformity by hotels, boarding-houses, and dwellings for lease, to the requirements of modern hygiene.

The question is often asked as to what quarter of New-

port is best suited for winter residence? My reply is always unhesitatingly, "the Point," and this not merely because it best suits my own taste for quiet and yet accessibility to the centre of the town, and that it is the only shore whence the use of boats is possible in all weather and at all seasons of the year, and that as the residence *par excellence* of Philadelphians, especially of Germantown people, during the summer, it is becoming better appreciated with every year, but it is completely sheltered from easterly weather. The drier northwest winds are temperable by a furnace and outer sashes; easterly winds, even the comparatively mild ones of Newport, are not to the same degree.

That the writer sought Newport as an invalid six years ago, and solely for its winter climate; that he has remained there, partially convalescent, but in far better health than theoretically he could ever have hoped to regain, and that he is no longer in active practice, may possibly render his opinion, as to the advantages of the place as a winter health resort, of the more weight with the profession.

As the result of the present inquiry, it may be seen that, despite the theoretical assumption sometimes urged, that the main Gulf Stream lies too far off shore from Newport to exert any real influence upon it—

I. The southern character of both the fauna and flora of Newport prove the immediate proximity, presence, and direct influence of the warm waters of the Gulf Stream; and that—

II. The contact of its atmosphere during winter with this relatively warm sea produces a sensible modification of the local climate of Newport to such an extent that, already insular, it becomes, and even more distinctly than its favorable thermometric averages would imply, truly oceanic as compared with that of the neighboring mainland coast.

Progress of Medical Science.

THE SEVENTH SENSE.—Sir William Thomson, Professor of Mathematics in the University of Glasgow, in a recent address, broached the idea of the existence of a magnetic sense. This sense he called the seventh sense, to distinguish it from our other six senses—namely, those of sight, hearing, taste, smell, heat, and force. He said that, in speaking of a possible magnetic sense, he in no way supported that wretched grovelling superstition of animal magnetism, spiritualism, mesmerism, or clairvoyance, of which they had heard so much. There was no seventh sense of a mystic kind. Clairvoyance, and so on, was the result of bad observation chiefly, somewhat mixed up with the effects of wilful imposture, acting on an innocent and trusting mind. If there were not a distinct magnetic sense, it was a very great wonder that there was not. The study of magnetism was a very recondite subject. One very wonderful discovery that was made in electric magnetism was made by Faraday, and worked out very admirably by Foucault, an excellent French experimenter, showing that a piece of copper, or a piece of silver, let fall between the poles of a magnet, would fall down slowly, as if through mud. Was it conceivable that, if a piece of copper could scarcely move through the air between the poles of an electric magnet, a human being or living creature, in the same position, would experience no effect? Lord Lindsay got an enormous magnet, so large that the head of any person wishing to try the experiment could get well between the poles; and the result of the experiment was marvellous, the marvel being that nothing was perceived. Sir William Thomson, however, was not willing to admit that the investigation was completed. He could not but think that the quality of matter in the air which produced such a prodigious effect on a piece of metal, could be absolutely without any

¹ Schott; Tables, Distribution and Variations of the Atmospheric Temperature in the United States, etc. Smithsonian Contributions to Knowledge, vol. xxi. 1876.

perceptible effect whatever on a living body. He thought the experiment worth repeating; and it was worth examining whether or not an exceedingly powerful magnetic force was without perceptible effect on a living vegetable or animal body. His own speculations had led him to conclude that there might be a seventh or magnetic sense; and that it was possible an exceedingly powerful magnetic effect might be produced on living bodies that could not be explained by heat, force, or any other sensation.—*British Medical Journal*, October 13, 1883.

MALIGNANT TUMOR OR TUBERCULOSIS OF THE TESTIS.—Mr. Butlin, in the *Medical Times and Gazette*, records two cases where tuberculosis of the testicle was mistaken for cancer. In both cases there was a rapid enlargement of the body of the testis, perfectly smooth, oval, and firm, without any sign of inflammation, characteristics which pointed to the presence of a malignant tumor rather than to a tuberculous testicle. Mr. Butlin, however, points out that the absence of elasticity is a great point in favor of the tumor being non-malignant. Another feature worthy of notice is, that in both cases the tumor was punctured, and yielded bright blood, which very quickly ceased to flow, and the hemorrhage was not subsequently renewed. In conclusion, the author remarks that the diagnosis in a difficult case will often rest chiefly on the importance attached to one or two symptoms, among which sufficient weight has not been given to the unequal consistence, and especially to the elasticity of the tumor.

DESQUAMATION OF THE INTESTINAL EPITHELIUM.—In his lectures on general pathology, Cohnheim considers the separation of the epithelium from the intestine in cholera to be entirely a post-mortem phenomenon. Virchow protests strongly against this view, insisting that exfoliation of the epithelium of the small intestine not only occurs during life, but that sometimes during life the exfoliated epithelium is evacuated. This occurs not only in cholera, but in spotted fever, and sometimes in typhoid. In reference to these observations of Virchow, Boehm (*Virchow's Archiv*, vol. xciii., 1883,) notes that a similar desquamation of the epithelium may be produced during life by the administration of poisons. It occurs in acute arsenical poisoning, and in poisoning by substances of the muscarin group. The animals in which this phenomenon is best observed are cats, which, after injection of muscarin or similar substances, exhibit choleraic symptoms, vomiting and purging, the motions being at first fecal, and afterward white and slimy; the slimy masses consist partly of isolated epithelial cells and partly of epithelial tubes like the fingers of a glove. In arsenical poisoning the epithelium undergoes peculiar alterations within the intestine; the body of the cell swells up to a hyaline ball, the margin splitting into the form of small cilia, cells thus altered looking very like flagellate monads, from which they are distinguished, however, by the absence of motion, and by the fact that all the intermediate forms, from an unaltered intestinal epithelial cell to a ciliated ball, can be seen together in a single field.

THE ETHER DOUCHE OR LAVEMENT FOR LOCAL PAIN.—In the *Medical Times*, September 8, 1883, Dr. C. H. Hughes says: A recent paragraph, referring to the ether spray in the cure of neuralgia, prompts me to call attention to the fact that ether lavements have been employed by me in all painful surface affections for many years, whether with or without inflammation, but mainly in neuralgic affections. In facial, sciatic, and cervical neuralgias, no remedy except galvanism has given me such signal satisfaction during the past ten years of my practice in neurology. These lavements will cure some cases of recent origin; they will relieve all. I use the ether douche, not the spray, and Dr. McLane Hamilton is in error in his reference to my treatment of the intense pain of cerebellar abscess by ether spray. In the case

referred to, which I reported in 1877 (*Journal of Mental and Nervous Diseases*, October), I simply poured the ether on the head so copiously as to benumb all sensibility and restore a state of ease and mental tranquillity to a patient absolutely maddened with pain. The ether douche or lavement in trigeminal neuralgia is quite uncomfortable to many persons, on account of the unpleasant impression of the ether on the nose and eyes; and when applied to the supra-orbital region great care should be taken to keep the ether out of the eyes by laying the head back and covering the eyes with a handkerchief. If the ether should get in the eyes, the patient should be cautioned not to rub them, but simply to sponge the eyes with cold water and wait patiently till the ether evaporates. The same is true in regard to ether getting in the ears. There is no need of a spray apparatus for ether. It should be used freely, in quantities adequate to the effect desired. It should be poured on the part till relief is obtained. I apply it in this way to the motor regions of the head and down the spine in general or unilateral chorea likewise. No better agent can be employed for cephalalgia and for acute muscular tremor than the ether douche or lavement. Of late years I have heard of the ether spray, but the ether *douche* or lavement has been with me a most common and efficient agent in the local therapy of pain, especially superficial pain, for more than a decade, ranking with electricity, and better than mechanical vibration.

PARALDEHYDE AS A HYPNOTIC.—Paraldehyde has during the past year been made the subject of occasional contributions from various sources to the journals. Its introduction as a drug is due to the Italians, and especially to Cervello, of Palermo, and Morselli, of Turin. The medicinal dose is from thirty minims to two fluidrachms. Dr. J. C. Wilson has found a drachm to be the average dose for an adult under ordinary circumstances. It is to most patients disagreeable, and must be administered with a considerable draught of water. The taste and odor are ethereal and penetrating. Patients complain of this taste several hours after taking it, and it may be recognized by its odor in the breath. It is probably eliminated unchanged by way of the lungs. Dr. Wilson has prescribed it in nine cases, with a view to its influence as a pure hypnotic. In one hysterical patient it acted well for a short time, but lost its effect, and was discontinued. In a patient who could not sleep, after having acquired the habit of watching an invalid at night, it procured prompt and refreshing sleep. In a lady rendered sleepless by a sudden and appalling bereavement, it caused sleep, but was abandoned on account of the nausea which followed its administration. A gentleman who had sleeplessness and great mental depression after a debauch, and who failed to sleep for several nights after reasonable doses of the bromides and chloral, took a drachm of paraldehyde, and slept seven hours, waking refreshed and hungry. On the next day, this patient, being disturbed after he had taken it, failed to sleep, but succeeded in sleeping on taking a second dose. The other cases were sleeplessness from ordinary causes, and were all more or less fully relieved. It appears to speedily require an increase of the dose. Dr. Wilson ventures to express the personal view, that paraldehyde will prove a useful addition to our sleep-inducing drugs, but will supersede neither chloral, which it resembles in its effects, nor any others among them. It is, like new products of the chemical laboratory, at present expensive. There is no reason why a demand for it should not cheapen it.

ON LEAD POISONING.—Harnack came to the conclusion from his experiments that lead was a muscular poison, causing a peculiar loss of irritability of the muscular substance, so that when a muscle was subjected to the action of stimuli at regular intervals, it responded by very unequal contractions, which were sometimes large, sometimes small, and sometimes entirely absent, al-

though the stimulus was of equal strength in each case. A number of experiments have been made by Von Wyss (*Virchow's Archiv*, vol. xcii., 1883) on this subject, and he finds that lead tri-ethyl causes in frogs restlessness, quivering of the whole body, and loss of spontaneous movement, followed by loss of reflex action. The result was exactly the same as that obtained by Harnack, but the author thinks that it is simply that of complete paralysis of the central nervous system. At this time the muscles of the body were readily irritable, and continued to be so for several hours. After twenty-four hours, when the animal was entirely dead, the muscles presented a peculiar whitish discoloration and stiffness. This appeared earliest, and was most intense in the neighborhood of the injection, and presented the greatest similarity to a weak caustic action, while the general action on frogs was exactly that observed by Harnack; the author could not find any marked evidence of muscular paralysis. The muscles become paralyzed at a very late period after poisoning, and no difference could be detected between the irritability of a poisoned muscle and one from which the poison had been excluded by ligation of the afferent artery. These experiments, therefore, appear to show that lead has no special affinity for the muscles, and is not to be regarded as a muscular poison. On the other hand, the acetate of lead tri-ethyl is a powerful poison for frogs, and appears to paralyze the central nervous system. When lead is administered to frogs internally in increasing doses the animals die with epileptic convulsions. These facts appear to indicate that lead has a tendency to affect the central nervous system rather than the muscles, and that the cause of lead-poisoning is to be sought in an affection of the nervous system rather than of the muscles.

LOCAL ANÆSTHETIC ACTION OF CHLOROFORM.—Dr. Heusner writes, in the *Deutsche Medicinische Wochenschrift* of October 31, 1883, concerning a little procedure adopted by him to facilitate the local application of chloroform for the relief of superficial pains. Although chloroform will be absorbed in greater or less degree in whatever way it is applied to the skin, yet its irritant action is much less marked and its anæsthetic effect equally as great if it can be applied only in the form of vapor. To obtain this mode of application easily and without any waste of the drug, the author had made some shallow cups of tin, curved in such a way that they might be applied closely to the skin of the face, trunk, or extremities. To render them air-tight when on the skin, the rims of the cups were provided with rubber edges. To the outside was attached an elastic band, to retain the cups in whatever position might be desired, and inside was fastened a pledget of lint. When used, a few drops of chloroform are poured on the lint and the cup then inverted over the painful part. A sensation of tingling and warmth is first felt, which soon passes on to pretty severe burning, while the original pain becomes more faint. A moderate pain may be entirely cured, and even very severe pain is rendered quite tolerable. Dr. Heusner has used this mode of application successfully in pleurodynia, dry pleurisy, gastralgia, earache and headache. It is of little use, however, in deep-seated pain, and often the worse forms of neuralgia are uninfluenced. Instead of the specially made cups a simple wine-glass will answer the purpose. The applications should not be too long continued for fear of causing vesication.

A NEW METHOD OF TREATING CHRONIC RHEUMATISM BY ELECTRICITY.—Professor Seeligmüller claims to have met with remarkable success in the treatment of chronic articular rheumatism by electricity. He uses a metallic brush electrode with stiff wires, which he connects with the negative pole, the positive pole being attached to a flat sponge electrode. The latter is dampened and placed on the limb near the offending articulation, then the metallic brush is applied over different parts of the

joint, being held in contact with the integument in each place for the space of from one to ten seconds. The application is very painful, but the professor remarks that the patients soon grow used to it. After a sitting the skin is covered all over with little dots, looking as if the Baunscheid instrument had been employed. The mode of action, the author does not explain, but thinks it cannot be entirely owing to the counter-irritation, for he has used other equally severe cutaneous irritants without meeting with anything near the success obtained by this method. One patient, who had been treated for eight years for chronic rheumatism by all sorts of methods, was able, after the first application of electricity, to raise his arm, which had been powerless for six months; after the third application all the movements were normal. Another man was unable to move either his wrist or his shoulder, owing to rheumatism, and after five sittings was discharged as cured, and was able to resume his work as a stone-mason.—*Deutsche Medicinische Wochenschrift*, October 17, 1883.

ANGINA PECTORIS AS A SYMPTOM.—In a recent clinical lecture, Dr. Landouzy (*Le Progrès Méd.*, 1883, Nos. 35 and 36), reminded his hearers that angina pectoris should not be regarded as a morbid entity. Like epilepsy, it is not an autonomous disease, and, like it, there is no such thing as angina pectoris as a unity. No doubt there is a dramatic completeness about an attack of this affection: retrosternal pain, anxiety, painful immobility, pallor, cold sweat, painful irradiations down the cervical and brachial nerves. This completeness attracts the attention of the patient and physician, so that it has come to be regarded as always presenting the same characters and bearing the same grave prognosis. But this involves an error, not only doctrinal, but of great practical importance. Just as there are epilepsies which depend on this or that condition, more or less transient or amenable to treatment, so there are anginas which may be due to transient or curable conditions. This form of purely nervous angina is well attested, but deserves to be better known. These patients have more to complain of than to fear; the angina is one of the numerous phases of their neurosis, which may depart after a time never to return, is never dangerous to life, and depends on a mere functional derangement of the nervous system. In another type, the occasioning causes are obscure, irregular in their effects, and instead of the kind just related are usually a little fatigue, an emotion, or some slight digestive trouble. No doubt, there is some pathological element which determines the occurrence within one minute of an attack which was absent a minute before. But this is often hard to define, as such attacks may come on when the patient is in perfect repose, sometimes in bed, and often during the first sleep. It may sometimes happen that a patient with some slight cardiac lesion, who is also nervous, may have angina, which should be ascribed rather to the neurotic temperament than to the cardiac lesion. Thus Mme. K.— had a slight aortic obstruction; but after the menopause she became decidedly nervous, with sudden attacks of flatulence, outbursts of laughter and tears, œsophageal spasm, neuralgia, transitory paraplegia, palpitations, asthma, loss of memory, difficulty of articulation, slight convulsive seizures, etc. Upon these supervened an attack of angina, which, in virtue of her cardiac lesion, was alarming. The aortic lesion under treatment appeared to improve; but the neurasthenia increased, diabetes supervened, and then new attacks of angina appeared, and these were regarded as rather the results of the neuropathy than of the cardiac condition; and she was told that they were no more dangerous than the asthma, palpitation, neuralgia, etc., which had so long troubled her.

A NEW CODE SOCIETY has been organized in St. Louis, Mo. It is called the Pathological Society.

THE MEDICAL RECORD:

New York, December 22, 1883.

THE PATHOGENY OF RICKETS.

WE are indebted to the philosophical treatise of Bouchard on "Diseases Due to Retardation of Nutrition,"¹ for one of the best expositions yet given of the pathogeny of rickets.

Rachitism may be defined as an anomaly of nutrition in the child giving rise to an excessive growth of the osseous tissues, with imperfect calcification of those tissues; this entailing as a consequence temporary or permanent deformity of divers parts of the bony framework of the body. Rickets was for the most part unknown in Europe till the sixteenth century, and even during this epoch but one well-pronounced case is reported, and that by Theodosius in 1554, of a child, seventeen months old, which presented the characteristic deformities of the vertebral column and ribs. This appearance of rachitism in Europe just after the first great outbreak of syphilis, gives some support to the thesis so ably maintained by Professor Parrot (though on the whole not consistent with all the facts), that rachitism is always a manifestation of hereditary syphilis. Coming down to the seventeenth century we find the classic description of Glisson, bearing date 1650, and abundant evidence that the disease was prevalent in Switzerland, France, Holland, and Germany, as well as in England.

Many opinions have been advanced as to the nature of this disease; some authorities, as Portal, regard rickets as common to these four diatheses, syphilis, scurvy, scrofula, and gout, of any one of which it may be a manifestation. Hufeland ascribed it to scrofula, Boerhaave to syphilis; Glisson considered it as identical with osteomalacia, an opinion supported by Trousseau, though ably combated by Virchow.

Rachitism exists in all parts of the world, but is especially frequent in cold, damp climates. It develops preferably in houses deprived of pure air and sunshine, and hence is more known among the poor than among the rich, and is especially a disease of crowded cities. It manifests itself during the period of first dentition. Very frequent between six and thirteen months, its frequency diminishes between the ages of one year and five, and it is rare at puberty. Glisson was the first to remark the influence of defective alimentation on what he considered the osteomalacia of infants. Premature weaning is assigned as the principal cause by Petit, and too long deferred weaning by Zeviani. The experiments of Guérin

have often been appealed to in explanation of the pathogeny of this affection, this experimenter having succeeded in rendering dogs rachitic by feeding them exclusively on meat. It has also been sought to establish experimentally the influence of an alimentation poor in phosphate of lime; Dusard, Wegner, and others have thus succeeded in producing rachitic deformities in animals, recognizable by their histological lesions. The experiments of Heitzmann and Tessur go to show that the ingestion of lactic acid by animals whose food is poor in phosphates favors rachitism. Thus far one of the essential elements of rachitism is grasped, the lack of phosphate of lime in the ossifying tissues, but no explanation is given of the increased formative activity of the bony medulla. Bouchard believes it to be the consequence of the failure of calcification; the protoplasmic elements finding themselves no longer imprisoned in their calcareous envelope, are free to proliferate luxuriously.

Too prolonged nursing, premature feeding of the suckling with meat or potatoes, are conditions which may be attended with imperfect supply to the growing organism of lime and even of phosphates. Insufficiency of acidity of the gastric juice, excess of alkalinity of the intestinal juices by diminishing the solubility of phosphate of lime or favoring the precipitation, oppose the absorption of this salt. The use of the salts of lime, lime water, calcic carbonate (so much employed in the therapeutics of infantile complaints), has certainly the effect, judging from the experiments of Kletzensky and Rehn, to prevent the absorption of phosphates in any notable proportion, and increase their elimination by the feces.

In this question of phosphate of lime and its fixation in the anatomical elements, it will not do to lose sight of this particularity, that in all probability the phosphate of lime utilized does not enter the economy in the state of phosphate of lime. The lime penetrates on the one part, in the condition of chloride, or in combination with a vegetable acid, for in the form of phosphate only minute quantities can be absorbed; the phosphoric acid enters the circulation as an alkaline phosphate, or very probably, as Bouchard thinks, as phospho-glyceric acid. But if the theory of Bencke is true, if the phospho-glyceric acid is generated in the duodenum and absorbed in the intestine, its production demands the concurrence of numerous circumstances and almost complete integrity of all the digestive functions, for it supposes a high degree of acidity of the gastric juice, a notable alkalinity of the intestinal juices, and integrity of the biliary and pancreatic secretions.

The different steps in the formation of this complex organic acid are probably as follows: ingestion of fat and ingestion of soluble or insoluble phosphates; setting free of a part of the phosphoric acid of the phosphates by the hydrochloric acid of the gastric juice; emulsification, then breaking up of the fatty substances under the influence of the pancreatic ferment; production of glycerine, which combines in the nascent state with the free phosphoric acid. If the phospho-glyceric acid thus formed in the intestine combines later with lime in the recesses of the organism to form the phosphate of lime of ossification, it is at once seen that the question of pathogeny is removed from its once supposed basis, and that we are not so much concerned with the ingestion of phos-

¹ Ch. Bouchard: *Maladies par Ralentissement de la Nutrition*. Paris, 1882.

phate of lime with the food, or with its faulty elaboration, as with the divers physiological processes by which phospho-glyceric acid is produced in the alimentary canal. If now rachitic children ingest enough of fat, and even of alkaline phosphates, and even if the acidity of the stomach be sufficient, it is too often the case that they become sufferers from digestive troubles, the result of too rich food or a diet unsuited to their time of life, and that as a consequence of such faulty alimentation lactic acid predominates over hydrochloric acid in the stomach, a condition not favorable to the setting free of phosphoric acid; moreover, the alkalinity of the intestinal secretions may be insufficient, or these secretions may even be acid; a circumstance unfavorable to the decomposition of fat and the production of glycerine.

There are in rachitic persons other circumstances which interfere with the union of lime and phosphoric acid in the ossifying tissues, and the precipitation of this salt in the bone-forming cells. There are acid conditions of the blood which keep the phosphate of lime in solution, or cause it to be dissolved again after it has fixed itself in the cells. The fluids of rachitic patients are acid in a marked degree, and the peccant element has generally been found to be lactic acid, though acetic, formic, and even oxalic have been detected. What is the cause of this excessive acidity of the "humors" of rachitic patients? The solution of this question leads us deeply into the mysteries of nutrition and denutrition, of which we are just beginning to learn some facts. In a given time a healthy man completely transforms a determined quantity of organic alimentary matters, which, by successive steps of digestion and nutrition, pass in downward metamorphosis to the state of carbonic acid, water and urea. If during the same time only a lessened quantity of organic material can be completely oxidized, or if the same quantity is brought down only to inferior or intermediate degrees of metamorphosis, and if the various emunctories are called upon to eliminate not merely water and carbonic acid, but organic acids, fixed or volatile, not merely urea, but an excess of uric acid and of extractive matters, then we have retardation of nutrition, with all its attendant evils.

This nutritive languishment may result from insufficiency of alimentation, or from excess; in the latter case the blood becomes charged with imperfectly elaborated materials. It may also result from hygienic influences, which interfere with and retard respiration and circulation, and thus lessen the activity of the nutritive metamorphoses. Under these circumstances, the organic acids are not burned, the alkalinity of the fluids of the economy diminishes, uric acid augments in the urine, and the urates are more readily precipitated, and oxaluria supervenes. In these cases volatile fatty acids are eliminated by the sweat and perspiration. The histological integrity of the tissues is altered by the fact of the too ready solution or the imperfect fixation of the mineral ingredients which constitute the framework of the anatomical elements. The whole organism suffers, certain tissues more especially, and among these the osseous tissues.

Among the circumstances which favor this retardation of nutrition, it is needless to say that confinement in

impure air, such as results from residence in damp, shady, and ill-ventilated tenements, and want of outdoor exercise, are especially influential.

In its application to the disease under consideration, this fact of retarded metamorphosis explains why the *best fed* children as well as the *poorest fed* sometimes become rickety, as alimentary principles may be imperfectly digested, and fail to be appropriated, or the forces of denutrition may predominate over those of assimilation, as a consequence of alteration of the fluids of the economy entailed by some serious hygienic vice.

A field of profitable inquiry is opened by these considerations, which Bouchard improves by showing how other diatheses, as gout, rheumatism, glycosuria, are explicable by facts pertaining to retardation of nutrition. Pathologists have hitherto been too exclusively occupied with one side of the question of nutrition—that pertaining to the primary digestion, to assimilation, to organization. Therapeutics has been fruitful in suggestions as to the supply of nutritive principles believed to be wanting, and feeding and dosing has been believed to be the chief end of the physician.

There is another and no less important side—that of denutrition, of destructive metamorphosis, of waste, which is destined in the coming years to have more prominence, and to be more studied.

HOSPITAL SATURDAY AND SUNDAY.

CONSIDERING the preparations that have been made the coming week for the reception of Hospital Saturday and Sunday funds, and the conveniences that have been offered to that end in the admirable systematic distribution of the yellow boxes, the promises are good for a large contribution. At least there will be no excuse for even the humblest giver that ample opportunities are not afforded for the display of charity toward the sick and suffering poor in our hospitals.

No form of charity appeals more directly to the public sympathy than that which insures for the man stricken by disease or the victim of accident, the proper help in time of direst need.

The public are being gradually educated to the point of understanding how necessary it is to support the hospitals that are always so ready to help the sick poor. On the part of the hospitals, also, there is a commendable rivalry to do their utmost in that direction. It is indeed a matter of ambition, which cannot be too highly appreciated, to show a large list of urgent charitable cases that were promptly and efficiently cared for. Willing to encourage this disposition, the Hospital Committee has wisely decided to distribute the funds collected in proportion to such work done.

As we have said on previous occasions some of the hospitals on the list are running in debt on account of their free-heartedness, and the managers and other friends of these institutions bear the brunt of the deficiencies by personal donations. This certainly should not be allowed by a public capable of appreciating good intentions and of encouraging true charity.

The hospitals belonging to this Association have altogether over one thousand free beds for the use of poor patients. Even this number falls far short of the actual

requirements of a great city in which the population of the sick poor is very large, and in which the chances of sudden accidents are proportionately increased. It is really the poor who are oftener sick, and who are more frequently the victims of accidents. They are the emergency cases which must be provided for at all hazards and without question as to expense. If the hospitals stand ready to bear the burden and render necessary help besides, they should not be allowed to become pecuniarily embarrassed. But it is only necessary to bring these facts to the notice of the public to invite liberal responses. There is a reasonable promise that the auxiliary associations, of which there are now several, will do good work. Each dollar subscribed by these auxiliaries will insure for each sick member one day's treatment in hospital. Under such an arrangement any trade society of large membership can care for all its sick poor without any extra expense.

The wide distribution of collection-boxes gives opportunity to all. Even the humblest contributor can drop in his mite, and feel that he is doing as much in his way as the millionaire whose charities, disproportionately small, are often proclaimed from the house-tops.

PREMATURE SURGERY OF THE LUNGS.

WE noticed recently the pulmonary experiments performed on dogs by Biondi, whereby it was shown that considerable portions of one or both lungs could be removed with impunity, and even when one entire lung was extirpated recovery was as much the rule as the exception. Indeed, Dr. Biondi seems to think that the operation *per se* is attended with but little, if any, danger, for he remarks that his failures were attributable chiefly to the neglect of antiseptic precautions.

But we do not stop with dogs. The term pulmonary surgery already sounds familiar in our ears, and the reports of operations upon these vital organs in the human subject are appearing with increasing frequency in various journals, especially in the continental periodicals. In the *Deutsche Medicinische Wochenschrift* of July 18, 1883, is an account of an operation by Dr. Kaczorowsky upon a young girl who presented signs pointing either to an empyema discharging through a bronchus or to a cavity formed from bronchial dilatation. A portion of the sixth rib was removed, and through the opening thus formed the operator introduced his finger, pushing it through the lung-tissue until the cavity was reached. This was washed out and drainage established. Some improvement followed, but owing to a number of unfortunate circumstances the wound in the lung closed, and a reaccumulation of pus in the cavity occurred. The parents of the child objecting to a second operation, Dr. Kaczorowsky dismissed the case, and was unable to report upon the ultimate result.

In a journal published in this country, the *Medicisch-Chirurgisches Correspondenz-Blatt* for September, 1883, is contained a notice by Dr. Proegler of two instances of cauterization of the walls of a cavity, performed by Koch. The first case was that of a man with an enormous cavity in the lower lobe of the right lung. After resection of a portion of the sixth rib, the thermo-cautery was passed through the lung-tissue into the cavity, the

walls of which were then carefully cauterized. Some improvement in the quality and quantity of the expectoration resulting, the operation was repeated in four days, this time a piece of the eighth rib being removed. It was Koch's intention to operate a third time, but the patient meantime had died. The second case was that of a woman, who presented a cavity the size of a fist in the upper lobe of the right lung. The operation was performed as in the preceding case, and the patient was said to be greatly improved. Unfortunately, she died of septicæmia at the end of a week.

May we not express the hope that these examples will not be generally followed, at least for the present, for the measure of success thus far met with is not such as to give much encouragement to others. It would certainly appear preferable to let the poor consumptive end his days as peacefully as may be permitted him, rather than to subject him to the pain and distress of a formidable surgical operation, with a fair prospect of cutting short the few remaining weeks or months that might have been his on earth.

There certainly seems need of further experimentation upon animals before the human lung shall be considered a legitimate field for the exploits of the surgeon. And these experiments should be genuine efforts to relieve diseased conditions. Because a healthy dog will survive the removal of a part or the whole of one lung, it by no means follows that a like result is to be anticipated in the case of a man whose lungs are infiltrated with tubercles and whose vital power is already greatly reduced. When it is found that an animal with tuberculosis can be cured, or even greatly benefited, by the cauterization or exsection of the diseased pulmonary tissue, it will then be time enough to make cautious attempts in the same direction upon the lungs of the human subject.

THE EXTENT TO WHICH A MEDICAL EXAMINATION CAN BE FORCED BY LAW.

AN interesting case, touching the extent to which a medical examination of the person can be forced for the purpose of obtaining testimony to be used in court, has recently been decided in the northern part of this State. The plaintiff, a lady, sued the Ogdensburgh and Lake Champlain Railroad Company for injuries said to have been incurred in a collision by reason of the negligence of the company and its employees. The defendant claimed that no serious injury was received by her, and that she was either feigning sickness or was suffering from a disease not caused by the alleged accident. In order to carry out this theory of a defence, the railroad company obtained an order requiring her to submit to an examination of her person by three physicians selected by the company, under the direction of a referee. The order also provided that such other physicians as the plaintiff desired, might be present at the examination, and that she should answer such questions as the physicians chosen by the company should put to her regarding her sensations and feelings at that time.

The plaintiff appealed from this order, and it was reversed by the higher court in an opinion, some parts of which are of interest and are as follows: "It is undoubtedly true that not unfrequently plaintiffs suing for

bodily injuries, do exhibit in court the injured part. Nor do we know of any reason why they should not do this, notwithstanding the exhibition may excite sympathy. And on the other hand, all unreasonable concealment of an injured part (not justified by any dictate of modesty or otherwise) may excite a doubt in the mind of the jury as to the genuineness or extent of the alleged injury. But we cannot admit the principle that, either in the presence of the jury, or in the presence of a referee, a party can compel his opponent to exhibit his body in order to enable physicians to examine and question and testify.

"Section 834 of the Code, forbidding a physician to testify to information obtained while attending a patient, necessary to enable him to act, is not strictly applicable to the question now under consideration.

"But, if the law will not permit a physician, voluntarily consulted, to reveal what he has learned, can it be that the law will compel a party to reveal, by exposure of the body and by answers to questions, facts to a physician to which he may afterward testify in court?

"There may be danger that in actions of this nature plaintiffs will exaggerate the injuries they have received, and that defendants may be at a disadvantage in ascertaining the exact truth. But this evil is far less than the adoption of a system of bodily and perhaps immodest examinations, which might deter many, especially women, from ever commencing actions, however great the injuries they had sustained."

THE VALUE OF RECREATION.

SIR JAMES PAGET has been addressing the Workingmen's College on "Recreation," and a great treat it must have been to the members to hear the "golden-mouthed" surgeon. It is certainly good for one whose position places him above all suspicion, as his good nature and sincerity puts him above envy, to display this interest in workingmen. He discoursed to them on change as the essential of recreation, but said that wonder should be awakened and the exercise of skill called forth. Then he tried to show that special pleasures are a sort of survival of our ancestral instincts. Our forefathers had to clear the forests, make roads, fish, hunt, and so on. Sir James is strong on hereditary habits and instincts, but we do not suppose he would go in this direction further than to the time when all were hunters. Perhaps after all those are right who look for the greatest degree of change in employment as recreation. Thus mental should give way to physical exercise. At any rate, it has been found that students, although relieved from fatigue by sedentary change, do not benefit so much as when they cease to make mental efforts. A game of chess may be very well after a spell of medical study, but a game of cricket would be better for any one who has physical energy enough to enjoy it. So to workingmen an evening at their college should be regarded as recreation—the process being merely reversed.

M. CHARCOT has been elected a member of the Academy of Sciences, Section of Medicine and Surgery, in place of the late Baron Cloquet.

News of the Week.

THE LATE DR. J. MARION SIMS.—At the last meeting of the Newport (R. I.) Medical Society, Dr. Samuel W. Francis, Vice-President, presented the following resolutions, which were adopted:

Whereas, It has pleased Almighty God to remove from this earth Dr. J. Marion Sims; therefore

Resolved, That, in his death, Science has lost a star; Surgery a pioneer: Gynecology an originator; America one of her philanthropists; and the fair sex their best friend.

Resolved, That the name of J. Marion Sims will live till woman dies.

Resolved, That the boldness of his operations was only equalled by his tenderness and sympathy at the bedside.

Resolved, That, as he belonged to the world, both hemispheres will mourn his loss and cherish his memory.

Resolved, That a copy of these resolutions be transmitted to the family.

THE PROPOSED MONUMENT TO THE LATE DR. J. MARION SIMS is taking a definite shape. We have received the first contribution for the same to the amount of ten dollars from R. C. Derby, Newport, R. I., on behalf of the Sanitary Protective Association of that place. This example will doubtless be followed by others. THE RECORD will gladly do anything in its power to make the project a success. No more worthy name than that of Sims could be chosen to represent the genius of the profession of this day and generation. As suggested by Professor Byrd, of Baltimore, the monument should be erected in Central Park. There is no more appropriate place than this. Any subscriptions to the fund will be duly acknowledged in THE RECORD.

SIR PRESCOTT HEWITT RETIRES FROM PRACTICE.—One of the recently created medical baronets has already disappeared from London practice. Sir Prescott Hewitt, always fond of sport, retires to the country, where we may wish him long life to enjoy his *otium cum dignitate*.

ACCUSED OF MANSLAUGHTER FOR TRACHEOTOMY.—A further illustration of the risks medical men run has turned up recently. A London surgeon is now accused of manslaughter for a tracheotomy after which the patient died. The father of the child when the operation was performed sucked the tube to free it, and thus contracted diphtheria from which the patient was suffering. He brought an action against his doctor for damages for not preventing him sucking the tube—the lawyers thinking with the father that the doctor should have himself taken the risk! Failing in this action, the bereaved parent, or his lawyers, seek to convict the doctor of manslaughter of the patient, which the operation did not save. When patients talk of gratitude and what they owe the profession such things as this should be remembered. One cannot help feeling that such actions are got up by an inferior class of lawyers.

THE MANUFACTURE OF CIGARS IN TENEMENT-HOUSES.—The act of the last Legislature prohibiting the manufacture of cigars in tenement-houses has already been brought before the Court of Appeals. The constitution-

ality of the act is disputed on the ground that it is an unauthorized interference with the private pursuits of citizens, and defended on the ground that it is a legitimate exercise of police power for the protection of the public health. The real question is whether cigar-making in tenement-houses is injurious to the public health in the sense that justifies an interference by the State to prevent it, or whether the real object of the law is not to prevent the competition of tenement-houses with the regular factories in cigar-making.

FEMALE PHYSICIANS IN INSANE ASYLUMS.—Dr. Sarah Stockton has been appointed physician to the female department of the Indiana State Insane Asylum.

SELLING ADULTERATED DRUGS.—In the test case against Billings, Clapp & Co., wholesale druggists, the defendants were found guilty last week of selling tincture of opium containing a less quantity of morphine than that prescribed by the Pharmacopeia. They were fined a nominal sum, and will take the case to the Superior Criminal Court.

CHARITY ORGANIZATION.—A very successful meeting was held at the Union League Club Theatre last week, for the purpose of popularizing the methods of the Charity Organization Society. Mr. Joseph H. Choate, Mr. Curtis, Judge Daly, and a number of others spoke. We can only regret that the medical side of the matter, which is not the least important, was not represented. The following interesting facts regarding the need and the supply of charity were given: In New York one in every twenty-seven receives charitable help. The experience of other cities which have adopted organization proved that only one-third of the applicants were entitled to immediate money relief; that only one-tenth required continuous relief; that between ten and twenty per cent. were impostors, and that one-half only needed advice and encouragement to help themselves.

BROOKLYN VITAL STATISTICS.—In his annual report to Mayor Low, Health Commissioner Raymond says the health of the city of Brooklyn during 1883 has been better than in any year since 1879. The total number of deaths in the city in the twelve months ending November 30, 1883, was 13,833 or 1,180 less than the actual mortality during the calendar year 1882. Estimating the population at 624,118, the death rate is 22.16 in each thousand of persons. Among other things Dr. Raymond says: "I am impelled to state my conviction that the efficient operations of the Department of City Works have vastly improved our sewer system, and for some months at least have given us pure air to breathe by giving us relatively cleaner streets under the new contract, and have thus indirectly come to the aid of the sanitary authority in its fight against zymotic disease." Attention is called by Dr. Raymond to the great need for new sewers in the outer wards of the city, which are now being so rapidly built up, and he also recommends that the slaughter-houses be removed from the crowded portions of the city.

A NATIONAL VETERINARY ASSOCIATION FORMED.—Delegates from various State Veterinary Associations held a meeting at Chicago on December 13th, for the purpose of forming a National Association. Among the

Eastern representatives were S. V. Plageman, of Brooklyn; J. Finley and W. J. Connody, of New York City. The morning session was devoted chiefly to a discussion of the eligibility of delegates. In the afternoon a permanent organization was effected under the title of the National Veterinary Medical Association, and the following officers were elected: *President*—L. V. Plageman, of Brooklyn; *Vice-Presidents*—W. C. Fair, Cleveland; William Sheppard, Ottawa, Ill.; W. T. Connody, New York; *Secretary*—R. A. Harding; *Treasurer*—A. J. Chandler, Detroit; *Corresponding Secretary*—Joseph Hughes, Chicago. In the evening a banquet was held, a constitution adopted, and the organization perfected.

A "NATURAL BONE-SETTER" SUED FOR MALPRACTICE.—One of the family of Sweets, of Connecticut, who have long been known for their reputed skill in setting bones, has been arrested and will be sued for malpractice. We believe that "natural bone setters," taking it all in all, do a great deal of harm, and ought to be abolished as public nuisances.

CINCINNATI AS A MEDICAL CENTRE.—Cincinnati has, according to a correspondent of the *Chicago Medical Journal*, four hundred and sixty-three doctors, "regular, irregular, and defective," five hospitals, two medical colleges, two medical libraries, five medical societies, three medical journals, and a health board, and an extra proportion of midwives and bogus medical colleges.

A NOVEL STRIKE.—It is rumored that the wet-nurses (*nourrices*) in the pay of the Assistance Publique, intend to strike. They receive from fifteen to eighteen francs a month, but consider it insufficient, as private families pay at a higher rate. The director of the Assistance Publique has enumerated in this year's budget a sum of one hundred and fifty thousand francs for the benefit of wet-nurses. It is unknown whether this is a coincidence or a result.

DR. H. Z. GILL has accepted the chair of Clinical and Operative Surgery in the medical department of Wooster University, Cleveland, O.

DR. W. H. HOOVER, of Philadelphia, died December 18th of Bright's disease, aged fifty-nine.

PROFESSOR ALONZO CLARK reminds us that we have, in speaking of the medical fathers of New York, bestowed on him more years than he deserves, he having been born March 1, 1808. We are only too glad to transfer the difference in calculation to the credit side of hopeful realization—and more, too.

ENLARGING THE OPPORTUNITIES FOR DISPENSARY WORK.—Several New York City dispensaries have evening hours, and recently a Philadelphia dispensary has adopted Sunday morning hours.

A CREMATORY ASSOCIATION has been formed in Washington, and Congress is to be asked to give it a charter. A German physician has given a lot on which to erect a crematory similar to that in Washington, Penn. One of its members says that the expense of burning a body will not be more than \$35, and that soon they may be able to reduce it to \$20.

TRICHINOSIS IN ILLINOIS.—Several cases of trichinosis have appeared in a German boarding-house at Bloomington, Ill. The disease was caused by eating raw sausage made from a hog raised in the place.

CHOLERA STATISTICS.—A communication from the United States Consul-General in Cairo, Egypt, to the State Department, gives an official statement of the cholera epidemic in Egypt, in which it appears that from forty-eight to fifty thousand persons have died of the scourge during the period from June to September 1, 1883. Dr. Salem Pasha, President of the Egyptian Sanitary Council, states that the Council of Health is engaged in collecting precise statistics of the number of victims. He also states that the disease broke out anew at Alexandria after it had disappeared, with a daily mortality of three to twelve persons. It has not re-appeared elsewhere. He says that the "Sanitary Bulletin," which was published during the prevalence of the disease, gave erroneous accounts, and instances one case in Cairo where the "Bulletin" gave the number of deaths on July 24th at 456, when in fact there were more than twelve hundred. It is believed the total mortality for four months will reach nearly seventy thousand.

In many villages a majority of the laboring population have died, while in others entire communities have disappeared, hardly leaving enough people to cultivate and harvest the crops. At Calcutta the deaths from cholera for the week ending October 27th numbered 20 out of a total mortality of 243.

YELLOW FEVER deaths at Havana, Cuba, for the week ending December 8th amounted to 23. Only two suspicious vessels sailed for American ports during the week: American schooner Elwood Burton, for Pensacola, and Spanish bark Antonieta, for New Orleans. In Mexico the disease still prevails, with twenty deaths at Acapulco, and several sporadic cases at Vera Cruz. A new outbreak of the disease at Orizaba is reported by Assistant-Surgeon Main, consequent upon too early raising quarantine against Vera Cruz.

EGYPTIAN RAGS are hereafter to be disinfected before shipment to this country. This precaution has been inaugurated by the State Department at the request of Surgeon-General J. B. Hamilton of the Marine Hospital Service. Pressure under steam and such other measures as may be found to be efficient for the purpose will be used.

MEASLES IN WASHINGTON.—Washington, D. C., is undergoing a siege of measles, and many of the public schools have been forced to close on account of the epidemic.

THE DWIGHT INSURANCE CASE.—Apropos of this now celebrated case, we have received a letter from Dr. Daniel G. Burr, of Binghamton, N. Y., criticising the action of the medical experts for the insurance company. There were, he writes, a well-known New York physiologist, a neurologist, and an Albany physician, who were most prominent as expert witnesses and "coachers" for the counsel. Dr. Burr says that these gentlemen worked and associated together, although two were staunch Old Code adherents, while the third was of homœopathic affiliation.

The turning-point in the suit was the post-mortem appearance of the neck of the deceased, the defence claiming that the person deceased had committed suicide by hanging himself in bed, the plaintiffs that he

did not. Fifty-eight hours after death an autopsy was held, which was conducted by Dr. Francis Delafield, of New York City, in the presence of thirteen or fourteen other physicians. Some six or seven of us average doctors who witnessed the autopsy were subpoenaed by the plaintiffs to testify to the question of fact, *i.e.*, whether there was any mark of a cord across the windpipe. Our testimony was duly given, we stating that *no such mark was present*. Despite this, the experts in question testified that his death was caused by hanging. At the time when this case came up, we expressed that opinion, based upon Dr. Delafield's careful autopsy that there was no evidence of suicide. Under our present system, however, it is expected that medical men will help the side for which they are engaged if they can conscientiously do so. Our correspondent is particularly indignant that the absolute facts, testified to by half a dozen "average doctors," should be ignored, or their existence practically denied under oath, by learned experts. And he concludes: "Is our civilization a failure? and the 'average doctor' played out?"

Obituary.

THOMAS S. KIRKBRIDE, M.D.,

PHILADELPHIA, PA.

THOMAS STORY KIRKBRIDE, M.D., Superintendent of the Pennsylvania Hospital for the Insane, died on December 17th at his home in Philadelphia. Dr. Kirkbride suffered a protracted illness about four years ago, from which he never fully recovered. Last spring he was again prostrated, and never rallied to any hopeful extent. For more than forty years Dr. Kirkbride's name has been familiar to the medical world as associated with the study of insanity. He was born near Morrisville, Bucks County, Pa., July 31, 1809. He was a descendant of Joseph Kirkbride, of the parish of Kirkbride, in the county of Cumberland, England, who came to America with William Penn. He received his education at Trenton, N. J., whence he came to Philadelphia and graduated at the medical department of the University of Pennsylvania in March, 1832. One month later he was appointed resident physician to the Friends' Asylum for the Insane, situated near Frankford, where he remained for one year; and in the spring of 1833 was elected to the same position in the Pennsylvania Hospital, which he held for two years, after which he engaged in private practice in Philadelphia. In the autumn of 1840 a new institution for the insane, now well known as the insane department of the Pennsylvania Hospital, commonly called "Kirkbride's," was so near its completion that it became necessary to select a superintendent. To this post, in October, 1840, Dr. Kirkbride was elected, and he remained the head of the institution until his death.

Under the promptings of Dr. Kirkbride and kindred spirits the association of the Medical Superintendents of the Insane Asylums of America was formed in 1866, of which he was President for eight years. He was elected a Fellow of the Philadelphia College of Physicians in 1839, was a member of the Philadelphia County Medical Society, the American Philosophical Society, the American Medical Association, and the Medical Society of the State of Pennsylvania. He was the author of the volume on "The Construction, Organization, and General Arrangement of Hospitals for the Insane," and on "Rules for the Government of those Employed in the Care of the Insane." In addition, he contributed a number of valuable monographs and reviews to the *American Journal of Insanity* and other periodicals. Personally

Dr. Kirkbride was remarkable for his genial temperament, which quickly endeared him to those members of the profession with whom he was thrown in contact. He was a man of modest and retiring character, but exceedingly clear and pronounced in all his social, political, moral, and professional opinions.

Reviews and Notices.

A PRACTICAL TREATISE ON MATERIA MEDICA AND THERAPEUTICS. By ROBERTS BARTHOLOW, A.M., M.D., LL.D. Fifth edition, revised and enlarged. New York: D. Appleton & Co. 1884.

THE author has adapted the present edition to the changes made in the sixth edition of the United States Pharmacopœia. He has also given the whole work a careful revision, incorporating the more recent improvements and additions to therapeutics. About one hundred pages are thus added to the volume. The valuable practical character of Dr. Bartholow's treatise has been recognized by the profession, and probably no one has succeeded better in popularizing the physiological in distinction from the empirical mode of studying therapeutics. The book is so excellent a one that we can hardly pick out any faults without venturing dangerously near hypercriticism. It appears to us, however, that there is a certain lack of definiteness in his description of the physiological action of the drugs; thus it is not enough to say that a drug increases the strength of the heart-beat and the volume of the pulse, we must know, and pharmacology does know in very many cases, upon what part of the nervous mechanism the action takes place. The book contains notice of several recently introduced drugs. The author would not, perhaps, recommend muscarin so readily if he knew that it was sixty cents a grain. He is, perhaps, a little too ready to recommend drugs, and to endorse their usefulness. All this, however, does not prevent the book from being a most admirable one, and a credit to American medicine.

SUICIDE: History of the Penal Laws relating to it in their Legal, Social, Moral, and Religious Aspects, in Ancient and Modern Times. By R. S. GUERNSEY, of the New York Bar. Read before the New York Medico-Legal Society, September 23, 1875. Revised and enlarged. New York: L. K. Strouse & Co., Law Publishers. 1883.

A MONOGRAPH on this particularly important medico-legal subject by an accomplished lawyer cannot fail to be instructive and interesting to the practitioner of medicine. Mr. Guernsey has certainly given us an admirably thorough, systematic, and complete treatise within the necessarily brief compass of a society paper. It is far from a bare digest of ancient and modern laws. If we may be allowed the comparison, the book resembles a well-written novel, not so distinctively from its pleasant grasp on the reader's attention, but from the masterly touches, which insensibly and without effort impress one with the motive behind the facts. Mr. Guernsey's wealth of research and aptness of illustration give us the side lights necessary to a rounded conception of each stage of his subject. We are made to understand so easily, as we advance, the social character of the period, that we appreciate at once the actions which induce the individual to suicide and the portent of the laws devised to meet each exigency.

The book is, on the face of it, a simple and unostentatious effort, and would naturally preclude anything like elaborate analysis or criticism (the few sentences we offer are certainly not intended to bear such an interpretation), but we have in it happily exemplified a manner of treatment which medical authors rarely attempt, or at least rarely attain. The average medical text-book is prac-

tically nothing but an elaboration of the quiz compend; and bears about the same resemblance, so far as method is concerned, to the work under consideration that an anatomical remembrancer bears to the better chapters of Ziemssen. The former is mechanical, the latter philosophical; the one gives at best an imperfect photographic, the other a stereoscopic view.

The fault of a medical man's style is due in a great measure to his imperfect literary training, but it is a very unfortunate fault, nevertheless, for it exalts memorizing at the expense of independent thought. The knowledge gained from the one is evanescent, from the other permanent.

The profession should learn more thoroughly to regard facts from a lawyer's standpoint. It would conduce to an exact balancing of evidence, and to an habitual suspension of judgment without evidence and hence to an accurate and adequate diagnosis. It would compel a presentation of facts that would appeal to the reason rather than the memory, and would in so far help to banish dogmatism from the lecture-room and medical literature and empiricism from practice, "a consummation devoutly to be wished for."

A MANUAL OF PATHOLOGY. By JOSEPH COATS, M.D., Pathologist to the Western Infirmary and the Children's Hospital, Glasgow, etc. With 339 illustrations. Philadelphia: H. C. Lea's Son & Co. 1883.

OF late years British and American students have had to depend for a treatise on pathology upon translations from the French or German, or such elementary textbooks as Green's "Introduction." It is, therefore, pleasant to be reminded that an English author can produce a work on this all-important branch of medicine which may compare favorably with foreign books. Dr. Coats has not attempted to write a new pathology that rests upon his personal observations alone, and yet an examination of his work plainly shows that it is no mere compilation. In fact, one of the best features of this treatise consists in the judicious admixture of foreign observation with private experience. Thus the subject is presented in a harmonious manner, facilitating the study of single topics, and making the entire volume profitable and even pleasant reading. The book is a rather bulky one, because the author includes in his descriptions general pathology as well as the special pathological histology of the different systems and organs. Many of the drawings are well-executed originals, and it is quite refreshing to be relieved from cuts that through frequent appearance in different works have bred the contempt of excessive familiarity. On the whole, it is but fair to say of Coats' pathology, that its author has succeeded in offering to English students and practitioners a thoroughly acceptable work that will now enable them to get along without translations.

TREATMENT OF DISEASES OF INFANCY AND CHILDHOOD, WITH OVER FOUR HUNDRED FORMULÆ AND PRESCRIPTIONS, as exemplified in the Services of Drs. A. Jacobi, J. Lewis Smith, Alonzo Clark, Austin Flint, W. A. Hammond, A. L. Loomis, W. H. Thomson, J. H. Ripley, T. Gaillard Thomas, J. R. Leaming, F. Delafield, L. A. Sayre, C. R. Agnew, L. Duncan Bulkley, Beverley Robinson, R. W. Taylor, G. H. Fox, F. N. Otis, A. A. Smith, E. C. Seguin, F. A. Burrall, E. G. Janeway, F. H. Bosworth, A. H. Smith, C. E. Billington, G. M. Lefferts, etc., etc., and in the hospitals of New York City. By CHARLES H. GOODWIN, M.D. Second edition, revised. New York: C. H. Goodwin, M.D. 1883.

WE are glad to note the cordial approval with which Dr. Goodwin's compact and complete little manual has been received by the profession, and the gratifying rapidity with which a second edition has been demanded. We take pleasure in congratulating its painstaking author, and in again commending the book to our readers.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, November 28, 1883.

GEORGE F. SHRADY, M.D., PRESIDENT, IN THE CHAIR.

DR. J. W. HOWE presented, in behalf of a candidate, a specimen of "Diffused Aneurism of the Popliteal Artery."

CHRONIC HYDROCEPHALUS.

DR. H. N. HEINEMAN presented a brain removed from a hydrocephalic child, two years old, and weighing only twelve pounds. It was interesting, especially on account of the thinning of the brain-tissue.

SARCOMA OF THE STERNUM, PLEURA, AND LUNGS.

DR. C. HEITZMAN presented a specimen with the following history: Dr. M——, forty-five years of age, came to his laboratory in April, 1882, for the purpose of having his blood examined, fearing the existence of leucocythæmia. For a year he had suffered from malarial poisoning, and claimed that his spleen was enlarged. Dr. Heitzman made a microscopical examination of blood taken from the finger, and found a decrease rather than an increase of the colorless blood-corpuscles; but the red blood-corpuscles exhibited a brown, reddish color, which he regarded as evidence that the normal formation of blood was being interfered with somewhere in the system, and he advised a change of climate, etc. At the same time Dr. M—— showed a tumor over the sternum, about the size of a pigeon's egg, movable superficially, but attached to the periosteum, and soft to the feel. Suspicion arose that it might be malignant, although it was stated that it had existed for a long time and had grown very slowly. Three months afterward Dr. Heitzman examined a specimen of blood drawn from the right pleural cavity of the patient, and found no pus corpuscles, no inflammatory corpuscles, but the red corpuscles exhibited the appearance already described. The fluid was non-coagulable. Dr. Gerster aspirated the pleural cavity several times, and subsequently Dr. Lange aspirated the tumor, and the blood removed from that was also examined, and exhibited elements which reminded one of sarcoma, although nothing specially characteristic was found. The diagnosis of sarcoma could only be suspected.

In August last another specimen of blood was sent to Dr. Heitzman, who examined it and found that of the few colorless corpuscles present many were undergoing disintegration, which always indicates approaching death.

Every time aspiration was performed, indicated by great difficulty of breathing, it was followed by considerable relief. In September dyspnoea returned, and while aspiration was being performed the patient died.

At the autopsy Dr. Heitzman found the body much emaciated. The tumor, then about the size of half a small goose-egg, was united to the periosteum, and on cutting into it an opening was found leading into the sternum, and large enough to admit his little finger. This perforation led to a cavity filled with blood, and evidently bounded by a tumor of the size of a small apple in the mediastinum. Both pleuræ were considerably thickened; both apices of the lungs were peculiarly changed into a callous-like substance, difficult to cut, somewhat resembling cirrhosis, but not having the gray color usually seen in old cicatrices in the lungs. There was a small quantity of blood in each pleural cavity. The heart was flabby. The liver was slightly increased in size, browner than normal, and showed very numerous dark purple specks, from which small drops of dark purple blood oozed, characteristic of cavernous tumors of the liver. The spleen was enormously enlarged, very firm, and gave a peculiar creaking noise when cut. All the other

organs were quite normal. The bronchial glands were somewhat enlarged.

The question arose, Was death due to an inflammatory process, or to a neoplasm? The appearance of both pleuræ indicated chronic pleurisy. Microscopical examination determined that the original tumor was sarcoma of the sternum, which grew inward rather than outward, and led to the destruction of the bone and the development of a sarcomatous growth in the anterior mediastinum. Both pleuræ and both apices of the lungs were transformed into dense fibrous tissue with innumerable aggregations of small globular bodies, which are seen with chronic inflammation and also in fibro-sarcomatous tumors, but the absence of inflammatory elements in the blood at previous examinations pointed toward the conclusion that the thickening was fibro-sarcomatous rather than inflammatory. The bronchial glands were sarcomatous. The little specks on the liver exhibited the usual features of cavernous tumors, or angiomas, and there was also interstitial hepatitis. The spleen was entirely destroyed. It contained myxomatous tissue, traversed by blood-vessels filled with blood, and evidently the organ was the seat of intense congestion.

The points of interest in the case were: (1) the remarkable combination of a malignant and benign growth, in the liver vascular tumors, and in the thorax sarcoma and fibro-sarcoma; and (2) although the tumor in the thorax was decidedly malignant, it gave rise to only few symptoms. Whether or not this peculiar feature was due to the impaired condition of the blood he was unable to say. To be sure, the condition of the spleen pointed directly to alteration in the formation of red blood-corpuscles.

DR. VAN GIESON said that about three years ago he presented a specimen in which the condition of affairs was just the reverse of that which existed in Dr. Heitzman's specimen—namely, primary sarcoma of the lung, and the sternum affected secondarily. With regard to the difficulty of diagnosis and the statement made by Dr. Heineman that more diagnoses of sarcoma and cancer of the lung and pleura are made post-mortem than during life, there might possibly be some difference of opinion. The diagnosis of the existence of a tumor of the lung, whether carcinomatous or sarcomatous, is sometimes a comparatively easy matter, when all the surrounding circumstances are taken into consideration, and the history of the case thoroughly known from the beginning.

In the case, the specimen from which he presented, there was no great difficulty in making the diagnosis, and it was confirmed by autopsy. Shortly after the report of the case was published he received from a gentleman, whose name he could not then recall, a table containing forty-five cases, and in over forty per cent. of those a correct diagnosis was made during life. In the case which he had reported, the symptoms were of such a character, it would seem, that no other diagnosis could be made which would account for them. There are cases, however, in which the difficulty of diagnosis is very great.

DR. HEITZMAN said that in one case he succeeded in making a diagnosis of sarcoma of the lung without even seeing the patient, and by examining the sputa, which contained globular elements smaller than pus-corpuscles or mucous corpuscles, and very numerous.

PERICARDITIS—ULCERATIVE ENDOCARDITIS—ABSCESS OF THE HEART—MICROSCOPICAL ABSCESES OF THE KIDNEY WITH COLONIES OF MICROCOCCI, AND THE BLOOD-VESSELS IN THE NEIGHBORHOOD FILLED WITH MICROCOCCI, RESULTING FROM THE INTRODUCTION OF A URETHRAL SOUND.

DR. GEORGE L. PEABODY presented the heart and one kidney removed from the body of a man who died of pyæmia following the introduction of a sound into his urethra. He had been treated on previous occasions for stricture above the bulbous portion, at no time close,

which admitted a No. 23 French. On November 18th a surgeon passed a sound, and on its withdrawal a few drops of blood followed, as had frequently occurred after the use of the instrument on previous occasions. Within twenty-four hours the man had a severe chill, followed by marked rise of temperature, delirium, and death on the eighth day.

Autopsy.—The heart showed the lesion of acute pericarditis, and also acute ulcerative endocarditis, with partial destruction of one of the cusps of the aortic valve. There was also an abscess in the heart as large as a small chestnut, just below the site of the aortic valves. The kidney contained abscesses, each surrounded by a zone of intense congestion.

Microscopical examination.—Dr. Peabody presented several microscopic slides, which showed micrococci in greater abundance than he had ever found before. Many of the abscesses in the kidney were of microscopic size. They contained colonies of micrococci, and the blood-vessels in their neighborhood were, very many of them, apparently completely plugged with micrococci.

DR. HEITZMAN asked whether Dr. Peabody examined the primary lesion, especially with regard to purulent phlebitis, which invariably precedes pyæmia.

DR. PEABODY said he examined the urethra with care and found no evidence of phlebitis.

DR. HEITZMAN also asked Dr. Peabody whether he held that the abscesses in the kidney were due to emigration of pus-corpuscles or to the breaking down of the entire kidney tissue itself.

DR. PEABODY said it was difficult to answer the question, because both conditions are found according to the stage of the disease in which the patient dies. In some of these abscesses it is evident that there is an intense aggregation of young cells without breaking down of tissue, while in others there is the same aggregation of cells but with breaking down of tissue. His own belief was that the presence of these irritants (micrococci) was sufficient to cause breaking down of tissue; and that they differ from other emboli in that they are distinctly infected by irritant properties, which are capable of causing the death of tissue in which they lodge. With regard to the pus, he believed that it originated here, as in inflammatory processes elsewhere, in part from colorless blood-corpuscles, but by no means entirely in that manner.

DR. HEITZMAN remarked that the statements made by Dr. Peabody fully agreed with what he had seen in abscesses of the liver and kidney.

SPINA BIFIDA—PARAPLEGIA, WITH LOSS OF CONTROL OVER THE VESICAL AND ANAL SPHINCTERS—OPERATION—CURE—DISAPPEARANCE OF THE PARAPLEGIA AND RESTORATION OF CONTROL OVER RECTUM.

DR. R. VAN SANTVOORD presented the liver and kidneys removed from the body of a boy twelve years of age. Early in life the patient was afflicted with spina bifida, attended by paraplegia and paralysis of both rectal and vesical sphincters. When six months old he was operated upon, and the result was a cure of the spina bifida, followed by restoration of power to the legs, almost complete control over the anal sphincter, but from early infancy he had been the subject of incontinence of urine. Occasionally he was unable to pass his urine and it was necessary to use the catheter. Sometimes he had a certain amount of control over the discharge of urine. The patient came under Dr. Van Santvoord's observation about the middle of last August. It occurred to him that possibly the cause of the urinary trouble might be contraction of the bladder, and he suggested the daily introduction of a catheter, with gentle dilatation by hydraulic pressure, but the bladder was found to be of considerable size. The boy soon began to lose his appetite, his urine contained pus and albumen, there was a daily elevation of temperature, and death occurred in November from exhaustion.

The autopsy was made by Dr. E. A. Maxwell, who found the bladder much thickened and sacculated; the ureters dilated—especially the left, which was larger than the small intestine, with enormous dilatation of the pelvis of the kidney on the same side—and filled with pus. There were abscesses in the structure of the right kidney and dilatation of the pelvis. The case, therefore, was one of spina bifida causing paralysis of the sacral plexuses on both sides, which was cured by an operation, and with the cure the paraplegia disappeared and control over the anal sphincter was restored. The dilatation of the left ureter was the most remarkable feature of the specimen.

HALLUX VALGUS—OPERATION—CURE.

DR. LEWIS HALL SAYRE presented the heads of the metatarsal bones of the great toe on each foot, removed on September 24th for the relief of hallux valgus. The man was forty years of age, and otherwise perfectly healthy. The condition had existed for many years. The joint on the right foot had suppurated twice, but no bone had ever been discharged. A straight incision was made over each joint and carried down through the periosteum, which was raised with an elevator, and the head of the metatarsal bone removed by means of bone forceps. The operation was performed antiseptically, horsehair drainage was employed, and the wound was closed with black silk sutures. Union was complete within two weeks, without suppuration. The patient was discharged able to walk without trouble and with movable joints.

ULCER OF THE STOMACH.

DR. BEVERLEY ROBINSON presented a specimen with the following history: H. G.—, male, single, fifty-eight years of age, a native of United States, and a salesman, was admitted to St. Luke's Hospital, November 13, 1883. Patient had been suffering four or five months from palpitations and dyspnoea. At present he has considerable cedema of the legs, no lumbar pains, micturition normal, no intestinal symptoms, no chest pains, temperature subnormal; urine 1.020, acid, faint cloud of albumen, a few epithelial scales; sonorous and sibilant râles are disseminated throughout the chest; more marked over left side; heart sounds feeble, though normal. Digitalis and whiskey were ordered.

November 14th, examined by Dr. Robinson. Old pleuritic adhesions are discovered on both sides of the chest. Considerable pleuritic effusion in lower half of right pleural cavity, less amount of effusion in left pleural cavity. Superficial pleuritic râles heard over both lungs, principally during inspiration, resembling sub-crepitant râles.

November 19th.—Patient becoming suddenly worse the house physician was called; when he arrived patient was quiet, comatose, breathing heavily; no jactitation; no sighing respiration; body and extremities not cold; heart action feeble. Night before patient had a bloody stool. Stimulated with digitalis and whiskey hypodermically; death.

Autopsy by Dr. F. Ferguson; notes by Dr. King, junior assistant.—Body is fairly nourished; rigor mortis is well marked. There is general anasarca. There are twenty-four ounces of clear serum in the peritoneal cavity. Diaphragm on right side is at the fourth intercostal space; left, fifth intercostal space. There are forty-eight ounces of reddish serum in the right pleural cavity, and thirty-six ounces in the left. There is one band of old adhesion at the apex of left lung, no adhesions on the right side. The heart is hypertrophied, its cavities are dilated; the muscular tissue contains fat; the valves are competent; there are some atheromatous patches on the anterior segment of the mitral valve; the aortic cusps are thickened. The lungs are in the condition of brown induration, they are poorly aerated. The mucous membrane of the bronchial tubes is normal. The spleen is normal. The kidneys are

lobulated, a trifle small; capsules are not adherent, surface is smooth and the markings are not distinct. The intestines contain blood, otherwise normal. There is an ulcer on the larger curvature of the stomach, irregularly ovoidal and two inches from the pylorus, with elevated edges (nearly half an inch above the rough bottom of the ulcer); there is a vessel in the ulcer plugged with fibrin, of considerable size. The mucous membrane of the stomach is markedly thickened; the stomach contains sixteen ounces of blood. The liver contains an excess of fibrous tissue. The brain is anæmic; there is atrophy of the convolutions; the lateral ventricles are distended with serum.

Microscopical examination made by Dr. Ferguson.—Stomach: There is no evidence of malignant disease in the neighborhood of the ulcer. It is surrounded by fibrous tissue, small areas of fat, and numerous small round cells of inflammatory origin, small spindle cells, and a few non-striated muscular cells. The muscular cells of the heart contain some fat-globules in places, but the transverse striæ can be seen generally.

Remarks.—"The features of interest in this case are: 1, patient did not accuse any local pain in stomachal or dorsal region while in the hospital; further, he digested the ordinary hospital fare without accusing any functional difficulty; 2, the absence of the usual symptoms indicating severe internal hemorrhage, such as jactitation, sighing respiration, and coldness of trunk or extremities."

ABSCESS OF THE SCALP—MENINGITIS.

DR. W. P. NORTHRUP presented a specimen with following history: Female child, aged eight months; New York Foundling Asylum. Was brought to the Out-door Department, November 13th, with symptoms of erysipelas of the scalp. Child was irritable and restless. November 13th, was returned to the Asylum hospital wards, when the following points were noted. Well-marked abscess over the right parietal bone, general hyperæsthesia, stiffness of back of neck. Pupils sluggish, otherwise no eye symptoms. Nurse who returned the child said it had "inward spasms" all the previous day. While in the house it lay in a rather apathetic condition. When undisturbed it would lie quietly for a long time, and when tickled on the soles of the feet "twitched all over." Died quietly November 25th.

Autopsy, November 28th.—Body well nourished. Abscess undermining scalp, covering whole right parietal bone; scalp thinned, bone bared of its periosteum. Opening about size of a silver twenty-five cent piece over the boss, edges of opening sloughy, outer table of the skull undergoing rarefying osteitis. Fontanelles normal: scalp elsewhere normal. On removing the calvarium no fluid escaped. All the sinuses were examined; all contain fluid blood; nothing abnormal. The walls were entirely normal. Beneath the parietal bone of the right side the dura mater was adherent. Nowhere from the inside of the skull-cap could any signs of communication with the abscess be found, neither were there any discolorations nor localized congestion. Brain: Nearly the whole convexity was covered with a thick, continuous, greenish-yellow, fibrino-purulent exudation, so thick over most of the surface as to cover the largest vessels and hide their color; in some places the outlines of the large vessels were seen encased in a thick coating; the exudate extended irregularly around to the base and there was found in scattered regions; about the optic commissure and medulla there was no exudate; ventricles normal; vessels of pia mater injected, giving the bright reddish tint in strong contrast with the greenish-yellow exudation. Spinal cord: vessels of pia mater injected, no exudation. Lungs: Moderate hypostatic congestion. Heart, spleen, and kidneys normal. Liver fatty. Stomach and intestines showed moderate increase of tenacious mucus, with dull gray, sodden, mucous membrane; mesenteric glands enlarged, firm, and reddish.

A SKULL ONE-SIXTEENTH OF AN INCH THICK.

DR. J. A. WYETH presented a piece of bone removed with the trephine from the skull of an adult. It showed the average thickness of the skull and was the thinnest he had ever seen, being only about one-sixteenth of an inch thick.

The Society then went into Executive Session.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

Stated Meeting, November 2, 1883.

GEORGE F. SHRADY, M.D., PRESIDENT, *pro tem.*, IN THE CHAIR.

DR. VIRGIL P. GIBNEY presented

A CASE OF MULTIPLE JOINT DISEASE OF SYPHILITIC ORIGIN OCCURRING IN A PATIENT WITH SCROFULOUS CARIES OF THE KNEE.

The subject of the present history has been under the observation of the out-door department of the Hospital for the Ruptured and Crippled, since February, 1872. At that time she was three years of age, and the diagnosis recorded then was synovitis of the left knee.

From February, 1872, to February, 1876, there are no notes in the case; but in this interval suppuration appeared and continued, so that in February, 1876, a note was made that an examination of the urine presented negative results. It was thought at that time that lardaceous changes were developing, but the urine furnished no conclusive evidence.

At the present time the mother is quite positive in stating that swellings about the wrists, fingers, and ankles were only from six to eight months' standing. But a reference to notes recorded under date of March 16, 1877, shows that there were eleven open ulcers, varying in size from a line to half an inch in diameter, without very profuse discharge; a knee ankylosed at an angle of 145°, with outward rotation of the leg over a small arc, and no very marked bony enlargement.

It is further recorded that on that date she stood and walked with comparative ease, *i.e.*, when a knee-splint was applied. Mention is also made of the right ankle in the following words: "Still boggy, though motion tolerably good, and no pain." And concerning the wrists it is recorded: "About the same condition; uses the hands well." So that it appears now that these swellings have existed at least six years, and that the mother's present anxiety is due to an increase of the joint deformity. It was also recorded on the above date, in the way of family history, that this child was the eighth of ten children; that the first died when fourteen days of age; the second was living and healthy at this time; the third was premature and still-born; the fourth had cicatrices and several granular swellings about the neck, of three years' standing, and was regarded generally as a scrofulous child; the sixth and seventh children were still-born; the ninth and tenth were still living and healthy.

In addition to the notes recorded, Dr. Ripley has quite recently examined the child, and found additional proof. For instance, he finds the mother had seven miscarriages or premature births, and that one of the children who had died was covered with an eruption called measles. The mother's throat showed loss of tissue about the pillars of the fauces, and one very characteristic cicatrix was seen just in front of the uvula. The patient herself had convulsions when four months of age, and shortly afterward a conjunctivitis for about two months; and had rubeola, followed by bronchial pneumonia.

At present she has epitrochlear glands almost as large as peas. The post-cervical glands are enlarged. The hair is thin; the spleen is enlarged; her throat and teeth show nothing characteristic.

From June, 1877, to August, 1879, the notes refer only to the condition of the knee from time to time, under different remedial measures, and especially under the calcium sulphide. The results were all negative.

No notes are on record in this interval bearing upon the other joints.

It was thought in August, 1879, that the wrists presented rheumatic signs, but a case was not made out. Iodide of potassium was administered, but not in large doses.

There is nothing further with regard to her wrists or fingers until July, 1883, when it was recorded that there were peculiar swellings about the joints of the upper and lower extremities, the wrist- and ankle-joints notably. Her urine at this time had a specific gravity of 1.008, without albumen.

During all these years she has had comparatively little pain. The discharge has been rather profuse from numerous ulcers, and yet the patient has gone about with little discomfort. The deformity of the knee has not increased. Numerous sinuses remain open, even from the middle third of thigh to the calf.

The knee-joint is pretty well ankylosed. The wrist swelling is peculiar, in that the radial epiphysis is enlarged, and the synovial sac is somewhat distended. There is bony enlargement about the distal ends of the first phalanx of the index and middle fingers. The second phalanx of the little finger is held flexed on the first phalanx. The swellings are not tender, and only occasionally painful. The tibio-tarsal joints present similar swellings, but the metatarsal and phalangeal are free.

The case seems to present both syphilitic and strumous elements, and they seem quite independent the one of the other.

The patient is presented to illustrate—1, the prolonged suppuration, extending over a period of ten years without any marked lardaceous changes; 2, the facility with which a patient thus affected can get about; 3, the immunity from pain; 4, the coincident swellings of other joints, and apparently of a different nature.

DR. SAMUEL SEXTON presented

A CASE OF EXCESSIVE AND TORMENTING ITCHING IN THE EXTERNAL AUDITORY CANAL OF SEVEN YEARS' DURATION, WITHOUT LOCAL LESION (PRURITUS AURIS).

The patient, a gentleman, aged forty-eight, had come to Dr. Sexton's office in February, 1877, with the following history: For one year previously there had been most distracting and intolerable itching in the left ear; sleep often had been impossible, and to relieve the itching he constantly scratched the inner extremity of the external auditory canal with the head of a large brass pin and rubbed the auricle with his hand. Some of the numerous physicians whom he consulted had advised him to instil oil, glycerine, etc., into the ear, and one of them informed him that there was an obstruction of the canal. He had occasional pains in the knees and hands, and about twice a week he had headache. He had long employed Hill's dye, an article supposed to contain sugar of lead, on the hair of his head and on the beard. Nasal catarrh existed in a mild form, but gave rise to no complaint. The external auditory canals were large and the inner end of the left one and the parts about the anterior superior quadrant of the left tympanic membrane were considerably injected by the constant use of the pin. The drum-heads were lustreless and the seat of trophic changes. The hearing was almost normal in the right ear, but somewhat impaired in the left; of this, however, he did not complain. The patient made two or three visits at this time, but treatment did not promise to give him any relief and he ceased to come.

In January, 1883, he came again, on account of the itching, which had not been relieved in the six years that had elapsed since his former visits to me in 1877. He had in the meantime again sought the advice of numerous medical men, and one of them, an aurist, under

whose care he was about a year ago, made a diagnosis of aspergillus and advised the instillation of dilute alcohol into the ear several times a day; this was kept up for six months, during which time he used several quarts of alcohol, at first under the doctor's observation, but without relief. This treatment at times made him dizzy. He also took Fowler's solution of arsenic at this time.

This case puzzled me very much, but my attention having been directed more particularly to aural neuroses since his first visit, I determined to make a more searching examination of the patient than hitherto, with the hope of getting at the etiology of the disease. In the first place it was ascertained that his mother and several brothers and sisters had broken down in health rather early in life; they were some of them especially subject to head troubles.

The patient himself, who is now fifty-four years of age, is well nourished. He finds, however, that his memory is failing, and that he is easily confused. He never has a single night's uninterrupted sleep, his dreams are unpleasant, and, especially after three o'clock in the morning, the itching and nervousness prevent rest entirely, and he arises feeling worse than when he went to bed. Mental depression is at all times very great; he has frequent headaches, and is easily fatigued by any mental or physical exertion, especially by the former. After the more marked periods of excitement he perspires freely about the head. For one or two years past he has had attacks, coming on suddenly every few weeks, of mental disturbance, characterized by a confusion of ideas and attended with a sense of heat in the head and cold extremities. An attack observed during a visit to my office was marked by slow pulse and frequent sighing.

These attacks, in which constant sighing and other nervous symptoms are observed, would in women, perhaps, burst forth as hysterical storms. In the case under consideration, however, the frequently recurring waves of depression seemed to discharge themselves, as it were, in unrestrained sighs.

Four months ago some new and very disagreeable sensations were experienced; there was an explosion in the left ear like a pistol-shot, which shocked him severely and gave rise to vertiginous symptoms; he was very nervous, and distressing tinnitus aurium of a roaring, buzzing character supervened; these symptoms were the cause of so much confusion that for a time the sense of hearing was entirely perverted and both mental and physical prostration were extreme. The next day autophony phenomena were observed. When he attempted to speak he could not understand himself, nor could the voice be modulated; it came and went, or, in other words, the autophony was intermittent. The next day after this attack being Sunday, he was very much bothered while preaching. Ever since the attack he has experienced frequent snapping in the left ear, occurring usually when he is in bed and all is quiet.

It is worthy of note that his life has been much of a struggle, and that since the death of his wife, which took place ten years ago, this has been increased.

Another fact seems of sufficient interest to be mentioned here, namely, a susceptibility to rhus poisoning. Ten years before the trouble began in his back—to be alluded to presently—he was frequently and severely poisoned by the rhus toxicodendron, the face and other parts, especially the scrotum, being much swollen. The attacks occurred several times during a period of four years, when he was engaged in handling the drug in a pharmacy. The eyes were often closed from the facial swelling, and he was sometimes confined to his room for several weeks. A son of his has a like idiosyncrasy.

An important fact remains to be mentioned: I allude to a trouble to which can in a measure be traced the aural difficulty. But a short time before the aural trouble began he experienced a severe itching on the back, between the shoulders, and extending from the nape of the neck to the lumbar region. It was not attended by any

eruption. This itching gave rise to great distress, interfering with his preaching and other work. After undergoing various treatment for this, including wet cupping, etc., he finally applied to a dermatologist for relief. A diagnosis of pruritus cutaneus was made, and a strong galvanic current was applied to the back so effectively at one sitting that *shortly afterward the trouble in the back ceased, but soon afterward began to manifest itself in the left ear.* The itching in the ear was more severe than it ever had been when confined to the back, since it never permitted him to enjoy a single night's rest. He now constantly found himself making desperate reaches for the spot of intensest irritation, usually employing the large brass pin before alluded to for the purpose, the head of which was inserted deep down into the canal. The ear, however, usually seemed worse afterward. He often rubbed the auricle violently until the friction was painful. Years ago he had practised pinching the auricle and the integument about it until the parts were red and sore, and thus masked for a time the deeper itching which he could not reach.

In general terms the patient's condition was fair, bodily nourishment being pretty good; the rheumatic diathesis had slightly increased, and the finger-joints were somewhat stiff. An important etiological factor was, perhaps, the long-continued dental irritation. The teeth began to trouble him at the age of twenty-five, and between thirty and forty they decayed very rapidly, giving rise to frequent attacks of periostitis of the alveolar processes. Only four years ago some of them were extracted. He has worn a large upper vulcanite plate for the past eighteen years.

The aural catarrh seems to have been uninterruptedly progressive; the drum head is less lustrous than when first seen; that the transmitting mechanism of the ear has suffered the acoustic phenomena before-mentioned plainly shows.

The inner end of the left external auditory canal is considerably macerated from the prolonged application of the alcohol, and some epithelium has exfoliated. It should be stated here that at no time when examined by me were there any other local disturbances or lesions present in the internal auditory canal than could be accounted for by the constant irritation caused by the violent scratching of the canal and the introduction of oils, etc., by the patient himself.

When a certain spot on the lower and posterior wall of the inner end of the canal is touched with the point of a silver probe, it is observed that the act of swallowing is performed, and although this reflex phenomenon is involuntary, the patient fancies that he does it to relieve himself of something that ought to be removed from the throat.

In considering the history of this case, with a view to adopting a rational plan of treatment, it was found, as has been above stated, that a certain degree of heredity existed; that periodical headaches had been experienced, which may or may not have been due to malarial influences. He had long experienced great irritation of the dental branches of the fifth pair of nerves, and perhaps above all he had suffered from mental troubles. That imperfect mastication of food from loss of teeth may give rise to digestive disturbances is evident enough, and we also have a history of the existence of a rheumatic diathesis. That the rhus poisoning and the effects of using a hair-dye containing lead about the head and face, may have had their influences in originally causing the itching in the back is probable. The acoustic phenomena, consisting of autophony and tinnitus aurium, are not to be considered as a direct cause of the itching, but rather as remotely influencing the trouble by increasing the mental distress. On arriving at a diagnosis in this case it appeared that the causative influences were mainly to be found in some central nervous disturbance, which, through the aural distribution of branches from the fifth cranial and the second spinal nerves, seemed to manifest

itself in the outward reflex that has been above described. Naturally, the prognosis was not encouraging, since the patient's age and habits of life were unfavorable.

The treatment consisted, in the first place, in recommending a more cheerful life, out-door exercise and other hygienic measures. It was believed that inasmuch as the dorsal cutaneous pruritus was very much less distressing than the aural symptom it would be well to invite a recurrence of the former while general mental and physical improvement were brought about, and accordingly irritation was produced on the skin of the back by means of painting with cantharideal collodion over small surfaces at a time, and he was encouraged to direct his attention to this region and indulge himself in any desire to scratch the parts.

Previously to this treatment it had been observed that pressure over the lower cervical vertebræ was somewhat painful. *For two days after the first application of the collodion was made there was no itching whatever in the ear,* and for a week subsequently it was scarcely observable, the patient speaking of it as a "dead itching." No desire to scratch the ear was experienced even during this period of time; it was the first omission in seven years to perform this act many times daily, although it had been long strictly forbidden. After several of these irritating applications, extending over some weeks, *the back finally began to itch severely,* and some of the post-cervical glands became enlarged and painful.

In the meantime the patient had been getting as much out-door life as possible, and had tried to free his mind from care.

At the end of a month the left ear was quite free of disagreeable sensations and whatever of them were at times experienced seemed masked, as it were. The right ear, however, was now occasionally the seat of titillating sensations. The above treatment began in February, 1883, and was continued until May, slight exacerbations being occasionally experienced in both of the ears, especially the left, while the itching of the back was less. Relief not being complete under the above treatment it was now determined to test the efficacy of occasional applications of a solution containing four grains of the sulphate of atropia to the ounce of water applied to that portion of the external auditory canal where the sense of itching seemed to be most intense. At first the effect was not satisfactory, the application appearing to increase rather than lessen the trouble. It was, nevertheless, persevered in and finally proved a source of relief whenever slight attacks came on. I am of the opinion that a stronger solution could be employed in some cases with advantage. It is to be hoped that further improvement will take place as the patient's general health becomes restored, but his condition is at present one of comparative comfort as compared with his former experiences; he regards himself as being seventy per cent. better than he was before treatment. The management of the purely acoustic symptoms I have purposely omitted, since they are only of special interest to the otologist.

DR. T. A. McBRIDE read a paper entitled,

PEPTONURIA.

He had observed last February that in some urine the addition of a saturated solution of picric acid produced a white precipitate, which disappeared entirely on the application of heat. This reaction was noted in some twenty-three cases. For reasons referred to later he excluded all but ten cases for study, and none of the ten had been under any previous treatment and had taken no medicines whatever. In the ten cases the exhibition of heat, nitric acid, and terchloroacetic acid had produced no precipitates. The precipitate was evidently not albumen. He then subjected the urines of the ten to the following tests: mercuric chloride, mercuric-iodide-potassium, Millon's reagent, tannic acid, argentic nitrate, plumbic acetate (neutral and basic), produced precipitates; absolute alcohol produced precipitate to some

extent. Dialysis was performed and the dialysate responded to all of the above tests. The following tests were applied to the urine and likewise to the dialysate without producing any precipitate: nitric, hydrochloric, and sulphuric acids; monochloroacetic, dichloroacetic, and trichloroacetic acids; acetic acid; acetic acid and ferrocyanide of potassium. The dialysis was conducted with great care and under the most improved method. The reactions indicated the presence of peptones, but no reaction had been obtained to the bi-auret or sulphate of copper and hydrate of soda or potassa test. Professor Charles Rice, who had corroborated the research so far in the specimens of urine and the dialysates thereof, advised concentration of the dialysate, and when this was done and the cupric alkaline solution added, a rosy-red color was very apparent. All of the reactions for peptones were thus obtained. The clinical consideration of the ten cases was deferred for the present.

Dr. McBride called attention in his paper to other precipitates produced by the addition of picric acid to urine, other than albumen and peptones. Hager in 1879,¹ and more recently Drs. Cook and Watkins,² called attention to the fact that a solution of picric acid produces a white precipitate in the urine of those who are taking quinine, whether in large or moderate doses. They have not stated, however, that this precipitate disappears on the application of heat. It should also be borne in mind that quinine in the urine answers to all of the tests for peptones, with the single exception of the bi-auret or the alkaline sulphate of copper test. One must depend on the absence of response to this test and to the history. In none of the ten cases investigated had any quinine been taken by the individuals. A solution of picric acid also occasions a precipitate of mucin when that substance is present in sufficient quantity. In three specimens Dr. McBride observed the precipitate was not great and did not disappear on the application of heat. Hager states that normal urine boiled with a saturated solution of picric acid yields a flocculent precipitate. Dr. McBride thinks that there is no danger of confounding this with albumen.

Dr. C. L. DANA referred to the experiments of Pohl and Meixner which, among other things, had covered some of the points of Dr. McBride's inquiry. These investigators had found peptonuria constantly in all chronic purulent diseases, abscesses, bronchorrhoea, cancer, the dissolving stage of pneumonia, and in acid urine in sixty-five per cent. of high fevers. The speaker himself had found traces of peptone in the urine after a full meal. It was sometimes desirable to estimate the amount of peptone in the urine. He had found some difficulty in finding a good method of removing the albumen and mucin from the suspected fluid. The former, if present, interfered with the characteristic purple-red color which pure peptone gives with alkalies and copper. The ordinary method of acidulating, boiling, filtering, then precipitating with alcohol was not always satisfactory. He had tried recently a test devised by Hofmeister and recommended and used by Pohl. This consists in adding to the fluid to be tested about three per cent. of a saturated solution of sodium acetate, then a solution of ferric perchloride, drop by drop, till the mixture is well reddened, then sodium acetate again until the reaction is neutral or feebly acid. On boiling this, all the albumen and mucin are precipitated, leaving the peptone, if present, in solution. The liquid is filtered and tested for peptone. The speaker believed with Dr. McBride that an examination of the urine for peptone might sometimes reveal or suggest facts of importance, such for example as an internal suppuration or cancer, or a beginning leukaemia. For peptonuria seemed to exist wherever there was an active movement of wandering cells.

Dr. F. P. KINNICUTT said that the use of picric acid as a *bedside* test for determining the presence of albumen

in the urine is open to many objections. It has been demonstrated that the peptones and other proteids are precipitated by it; among the latter mucin is to be particularly mentioned, as it is not re-dissolved by heat.

The presence of quinine in the urine, as Dr. McBride has mentioned, may also give rise to erroneous conclusions. As a laboratory test for detecting the presence of minute quantities of albumen and of *peptones* in the urine, I believe it to be of much value.

Dr. McBRIDE said that he thought the recognition of peptonuria was rather an important matter. A simple test for the presence of peptone was therefore very desirable. It was necessary to remove the sources of error that exist in the use of picric acid.

As regards the use of this acid as a test for albumen, it was first employed for this purpose as long ago as 1872, a fact of which Dr. Johnson, its introducer, seemed to be unaware.

Dr. F. P. KINNICUTT read the paper of the evening, entitled

THE TREATMENT OF ACUTE RHEUMATISM BY BLISTERS.

[The paper was published in a previous issue of THE RECORD.]

In opening the discussion, Dr. BEVERLEY ROBINSON said that in a considerable per cent. of cases the existence of a cardiac murmur in acute rheumatism does not indicate any inflammatory condition of the endocardium. There was always a considerable degree of anæmia in this disease with consequent relaxation of muscular fibre, including that of the heart, which became dilated, thus causing murmurs. Recently he had been using

BLISTERS OVER THE HEART

in certain cases of chronic cardiac disease with enfeebled action and accompanying dyspnoea. They were cases where the ordinary methods failed to give relief. The blistering seemed to strengthen the heart's action. From these experiences he could see how by using blisters in acute rheumatism some increase of the heart's power might be brought about, and thus lessen the effusion into the joints.

Dr. SAMUEL SEXTON said that some time ago he had occasion to look up the subject of blistering in connection with the aggravation of symptoms which seemed to take place in blistering over the mastoid process in inflammation of the middle ear. He then found that blistering the chest had been known to produce pleurisy, and clinical evidence seemed to show that severe blistering might increase inflammatory troubles.

HOSPITALS AND THEIR DRAINAGE—MORE DEATHS FROM MISADVENTURE AMONG MEDICAL MEN—THERAPEUTIC EXPERIMENTS.

LONDON, December 1, 1883.

PRACTICAL hygiene appears to be at a low ebb amongst hospital physicians and surgeons, for sanitary defects seem to be as frequent in medical as in other institutions. The Hospital for Sick Children, Great Ormond Street, has just been closed for some time for repairs and to overhaul the drainage. More than one metropolitan hospital has, I believe, had to pursue the same course within the last few years, and the state of some of our provincial hospitals used to be notorious.

I have to chronicle additional deaths amongst the profession. I have had to report several suicides lately. To the latter must be added the case of a Scotch medical student—presumably insane—who committed a double murder and then suicide. Two deaths from accidental poisoning have lately occurred. One was that of

¹ Pharmaceut. Central., No. 36.

² Medical Times, October 27, 1883. Philadelphia.

a well-known surgeon, Mr. James Shuter, M.A., M.B., LL.B., F.R.C.S., Assistant Surgeon to St. Bartholomew's Hospital. Mr. Shuter was a distinguished graduate of the University of Cambridge, a rising surgeon, and a popular and successful teacher. He seems to have by mistake swallowed about an ounce of a hypodermic solution of morphia (containing about forty grains of morphia) thinking he was drinking a saline draught he had prepared. Medical assistance was summoned, but was unavailing. The other death is that of a Brighton practitioner, Dr. J. M. Crombie, who died this week from accidentally taking an overdose of morphia. It is a singular fact that Dr. Crombie was the author of several papers on narcotics and anesthetics and their administration. Dr. Crombie advocated the self-administration of chloroform for the relief of pain and invented an apparatus for the purpose. Dr. Crombie's invention cannot be said to have been favorably received by the profession, who naturally have no wish to encourage so dangerous a practice as the self-administration of anesthetics. Dr. Crombie's own death adds yet another to the long list of unfortunate deaths from narcotics injudiciously administered, and evidently points the moral that too great care cannot be taken, even by experienced practitioners, in the administration of such dangerous remedies as narcotics and anesthetics.

A subject which has excited great attention in the papers lately is an escapade of Drs. Ringer and Murrell, who published lately an account of some experiments with nitrite of sodium. The effects of the drug were stated in such exaggerated terms, and the poisonous qualities of large doses so obviously shown, that the paper attracted the attention of the lay press, where the natural comment was that such apparently useless experiments on poor hospital patients were cruel and unjustifiable. Thereupon, of course, followed the howl of the antivivisectionists. The matter has since been explained to the satisfaction of a committee at the Westminster Hospital appointed to investigate the conduct of Dr. Murrell. It is well that he has escaped so easily, as he is a promising young physician and a censure would have much damaged him. I hope though the lesson will not be lost either on him or Dr. Ringer, or, indeed, on the host of men who are experimenting with potent drugs. Dr. Ringer only contributed the experiments on animals to the present paper, but I well remember his experiments on patients in University College Hospital, some years ago, with jaborandi. I then thought that it was as unjustifiable as it was useless to repeat doses which had acted so violently as to give rise to most distressing symptoms. I asked myself why he would not try smaller doses when repeating the experiments. Perhaps Dr. Ringer thinks it makes it even to administer infinitesimal doses of other drugs to other patients.

Army and Navy News.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from December 8 to December 15, 1883.

MCKEE, J. C., Major and Surgeon. Assigned to duty as Medical Director, Department of the Columbia, G. O. 31, Department of the Columbia, December 3, 1883.

SHUFELDT, ROBERT W., Captain and Assistant Surgeon. Now on sick leave, relieved from duty in the Department of the East, and assigned to temporary duty in the office of the Surgeon General of the Army. S. O. 284, par. 12, A. G. O., December 12, 1883.

Official List of Changes in the Medical Corps of the Navy, for the week ending December 15, 1883.

DEARBORNE, F. M., Surgeon. Placed on the retired list from December 10th.

HEFFINGER, A. C., Passed Assistant Surgeon. In addition to his duties at the Navy Yard, ordered to attend officers at Portsmouth, N. H.

THE EASTERN AND THE WESTERN PHYSICIANS AND THEIR RELATIVE ADVANTAGES.—Dr. J. A. Rafter, of Holton, Kansas, rather pointedly writes: "I have read with considerable interest the letters of Dr. Edmund C. Wendt that have appeared in the last three or four issues of your journal, in which he so well describes the different characteristics of the country and people of the great West and Northwest. I believe, however, that I voice the sentiments of nine-tenths of the profession of the West when I state that 'the impressions' of Dr. Wendt, from a medical standpoint, were hastily arrived at, and his deductions need many modifications. I think, still further, the tone of his letters are liable to make a false impression among the physicians of the East in regard to our professional attainments and standing. Several years' residence here, and something of an acquaintance among the profession, inclines me to the conclusion that Eastern and Western physicians differ but little, and that little is due to circumstances and surroundings. I have looked up the statistics, and as near as I can come at it, about one-half of the doctors practicing this side of the Mississippi are graduates from Eastern schools, and usually of New York or Philadelphia. Now I state it as a fair proposition that until the graduate turns his face westward he is (other things being equal) standing upon about the same level as the one who locates in New York, and speedily becomes 'professor' or 'adjunct professor.' The practitioner here can quote from the lectures of Flint, or Loomis, or the venerable Alonzo Clark as readily. They can practice medicine as intelligently, and surgery as successfully, as practitioners of the same ability there can do. In the face of this we can hardly forgive Dr. Wendt for saying (let me quote from his letter): 'Our Western confrère has perhaps heard of the Code. In rare instances he has even read it some, that is the old one. But he cares very little for it, and about as much for the new.' After this rather surprising piece of intelligence comes the most astonishing statement of all, 'He rarely hesitates to meet his homœopathic brother.' Now, without wishing to be impertinent in the least, I most emphatically challenge those assertions. I believe we are moderately familiar with the Code of Ethics, and are satisfied with it as it exists. We are only too familiar with the disgusting jangles that have been enacted in the Societies of the State and County of New York, and in the Academy of Medicine, by men whose petty jealousies and grasping ambitions have gotten the better of their heads. We are not proud of them here, and I am not willing to allow a stigma to rest upon the profession

of the West without a remonstrance, when it was a thrust given through them by a code contentions at those who possibly honestly differ with him nearer home. Neither do we claim kindred with pretenders, nor do we meet pretenders of any kind in consultation. We despise quackery, we despise deception probably as thoroughly as you do in New York. I will admit we are not as much given to recommending quack nostrums, but possibly the reason may be that we have no 'official position' to annex which will serve as an advertisement. We claim, and I think facts will justify it, that we are equal as practitioners to our Eastern brethren, and need not go to New York to learn 'differential diagnosis.' "

CAN WE SEPARATE MATTER AND FORCE?—Dr. F. A. Tuttle, of Jefferson, Ohio, sends the following very suggestive item: "Dear Sir—I see your London correspondent calls Maudsley the OLD name of materialist. Is force material? Can we separate matter and force? From the irritability of protoplasm up through reflex action, instinct, memory, reason, and will, are not the clustered nerve-cells always in proportion to the amount of mentality? Is it not humiliating to a thinking man working on a hypothesis, when puzzled, to call in the supernatural? We shall never learn how matter thinks, but is not the reign of law supreme there as elsewhere? Is not mind a phase of force? If not, why the need of constant supply of red, rich blood? Can we study this great question only with the inductive method? In an editorial a short time ago, reviewing Galton's inquiry into human faculty, you confessed you could not understand it. Neither can I; but the supernatural does not help us. It is just as easy for me to conceive how brain-cells think as to conceive how kidney-cells can eliminate poison from the blood. Where did they learn that strychnia and morphia are poison? How can matter taste, smell, or see? This awful mystery, could we understand it, is all founded on that one UNIT, the irritability of protoplasm; adaptation and heredity, working through the unchanging law of an all-wise Creator, tells the rest of the wondrous story. I do not know the ultimate nature of matter any more than I do the many phases that force may assume. Our profession must study the yet untold mysteries of insanity through the mal-nutrition of nerve-centres, as metaphysical moonshine has as yet afforded but little light to help us out."

WHAT IS MEANT BY THE SALE OF A MEDICAL PRACTICE.—The following statement of a recent English case, May 25. Thomson, appears in one of the legal journals: "The Master of the Rolls intimated the opinion, although the point seems not to have been decided, that a contract for the sale by a physician of his practice cannot be ordered to be specifically performed, as it is merely for the sale of a personal service, the vendor's introduction of the purchaser to the patients. He concedes that there is a good-will of an apothecary's business, or, as he called it, a 'doctor's shop,' meaning to include, doubtless, a physician who kept an office or shop where he sold to his patients the medicines he prescribed. The dictum does not throw any doubt on the assignability of a physician's practice, nor on the value of it, as a consideration for a promise to pay for the transfer, but only raises the nice question whether the Court would order the physician to perform such a contract, and enforce the order by process for contempt. The Master of the Rolls regarded the contract to introduce and recommend to patients as analogous to the contract of an actor or singer for his services, the performance of which the Court could not superintend."

VANILLISM.—A distinguished professor of the Faculty of Medicine of Bordeaux, Dr. Layet, has just read an interesting communication (*Lancet*) on certain injurious properties of vanilla, of which a satisfactory explanation has up to the present been wanting. The affections have been studied at a warehouse in Bordeaux, where on an

average 25,000 to 30,000 kilogrammes of vanilla arrive every year. In these storehouses the pods are cleaned, sorted, and classed according to their quality. These manipulations seem to cause certain symptoms among the workmen and women. At first an itching of the face and hands, associated with a powerful smarting sensation, is experienced, and the skin becomes covered by a pruriginous eruption, swells, reddens, and desquamates at the end of some days. At other times there is a feeling of malaise with dulness, stiffness, and muscular pains, which oblige the worker to give up this kind of labor. The cutaneous malady seems to be due to an acarus which appears as a small white rounded body occupying generally the ends of the pod. This insect does not penetrate the skin like the acarus scabiei, but determines the affection by its mere contact. Probably the parasite is aided in its irritant effects by the presence of "give" in the form of pale acicular crystals. The nervous symptoms M. Layet is inclined to put down to the manipulation of inferior pods of vanilla, containing much oily juice enveloping the seeds in the interior of the siliquæ.

CRITICISING THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—A correspondent from Hartford, Conn., sends us a very severe criticism upon the typographical inaccuracies of the *Journal of the American Medical Association*, especially with reference to the number containing a review of the Proceedings of the Connecticut Medical Society, 1883. We believe that the editor has explained the cause of the trouble.

DR. E. D. COONLEY, not E. D. Coonby, was the name of the correspondent on page 637.

OPHTHALMOLOGICAL METHODS IN PARIS.—A correspondent of the *Orvosi Hetilap* writes from Paris that the most eminent representatives of ophthalmological science in the French capital are foreigners of German, Polish, or Greek extraction. Among these he considers Dr. Meyer to be rather conservative. Dr. Gabrowski, who has the largest *clientèle*, is very fond of abstractions of blood. He orders leeches freely in different forms of conjunctivitis. He treats phlyctenular ulcers of the cornea by instillations of pilocarpine. For cataract he employs the old flap operation, without iridectomy, having entirely discarded Von Graefe's method. He uses the latter's knife, however, and makes the flap upward. He has made a series of about ninety of these flap operations, but has not yet published the results. De Wecker performs keratotomy for *ulcus corneæ serpens*, and follows up the incision by instillations of eserine. For the latter he substitutes atropine if there is a recurrence of hypopyon. For superficial abrasions of the cornea he also orders a solution of pilocarpine to be dropped into the eye. In cases of serous iritis, he avoids atropia and employs subcutaneous injections of the alkaloid of jaborandi. The number of patients at his clinique is smaller than at Gabrowski's, but his operative material is greater. He extracts cataracts by his well-known modification of Von Graefe's method. He uses antiseptic precautions. After performing tenotomy for strabismus, he closes the conjunctival wound by a suture applied in such a way as to approximate the angles of the wound and not the sides. He claims that by this suture the sinking of the caruncle is effectually prevented. He prefers sclerotomy to iridectomy for glaucoma. If the disease returns in an eye which has been already operated upon, he incises the scar. This operation he terms cicatriscotomy. He still continues his experiments of forcibly stretching the optic nerve in case of atrophy. The most peculiar notion of De Wecker is certainly his substitute for the protective bandage in cases of corneal ulcer. It consists in an apparatus made of glass and shaped somewhat like an artificial eye. This being introduced behind the lids allows the patient to see, at the same time that it protects his cornea from the air and the contact of the lids.

FUNCTIONAL DISEASES OF THE HEART.

By E. P. HURD, M.D.,

NEWBURYPORT, MASS.

(Continued from p. 540.)

PART III.—CLINICAL.

THE following interesting observation, from a recent work by Lecorché and Talamon,¹ may be regarded as occupying the border-land between functional and organic diseases. This case is regarded as a "cardiac affection of nervous origin;" an example of heart strain, "without valvular lesion, the result of violent passion." It well illustrates the effect of powerful emotion in deranging the heart, and the concatenation of morbid phenomena—asthenia, palpitations, arrhythmia, asystolia, syncope (*vide* Parts I. and II. of this series).

Professor Lecorché prefaces this report with the following comments: "The cardiac troubles were the manifest consequence of violent emotions. The patient was a very choleric, excitable man; during the Commune he had a narrow escape from death by being shot, and his hair turned suddenly white from the terror which this occasioned; it was finally a fit of anger which determined the crisis of cardiac oppression which brought him to our hospital. We noted in this person the most complete arrhythmia—a veritable 'folie cardiaque;' there was, however, no notable hypertrophy; the heart was somewhat dilated. We detected no souffle, and there was no œdema of the lower extremities, and no pulmonary congestion. It seemed to be wholly a case of disorder of the cardiac innervation. At the same time this man was a prey to an orthopnea as terrible as in the most advanced asystolia, with tendencies to syncope. Was there here a lesion of the myocardium? Has the arrhythmia ended in complete and permanent want of systolic power? We cannot say, nor can we be certain whether, in the event of his death, the autopsy would disclose any cardiac lesion referable to other causes than those of a moral or nervous character. This man had, in fact, been addicted at times to alcoholic excesses, and we know well that alcoholism entails arterial and cardiac degenerations. Hence it is that in questions of etiology the complexity of causes hardly ever, to an impartial mind, permits an absolute solution."

CASE I.—A case of "forced heart" without valvular lesion; arrhythmia.—Name of patient, J—, aged forty-eight; gilder; entered the Maison Dubois, February 6, 1879. Twelve years ago, after a drunken debauch, he had an unknown disease, referred by him to the intestines; was very sick; lost consciousness, remaining in this state four or five days. No other sickness; never had rheumatism.

Is very excitable and irascible. Has suffered great reverses of fortune. After the Commune he barely escaped being shot, and the alarm so affected his mind that he was insane for six months; his hair and his beard turned white from this fright. He never had previously suffered from any heart trouble whatever (whether palpitations or oppression), when, two months ago, as the sequel of a violent fit of passion, he was taken with an

attack of palpitations and precordial distress. Since then this disorder has never left him, and the least fatigue or emotion aggravates it, and puts him out of breath. No œdema and no cough. Urine scanty and high colored.

Present condition.—The patient cannot lie down, either night or day, his breath is short and labored, and his speech quick and interrupted. The least movement increases the dyspnea. Pulse weak, small, and irregular. The beatings of the heart are very irregular; sometimes they are slow, with prolonged pauses between each pulsation; sometimes precipitate, running riot, as it were, for eight or ten pulsations. The heart shock is very much diffused, and the area of cardiac dullness is greatly increased. The apex beats in the sixth interspace. There is no appreciable murmur, either at base or apex. No œdema of ankles. Pulmonary sounds are normal. No signs of congestion or œdema at bases. Urine scanty and loaded with lithates; free from albumen and sugar.

Treatment.—Digitalin, one granule night and morning. Morphia subcutaneously, *pro re nata*.

February 8th.—Dyspnea continues, with paroxysms of suffocation. Great prostration; at times lipothymia. Feels himself "going." Weight in the precordial region, and painful throbbings. Heart beats heavily, striking the thorax with dull, massive blows. Pulsations disorderly, slow or rapid, feeble or violent, with pauses, intermissions; one series of beats trespassing on the succeeding series.

February 9th.—Has had a prolonged faint with loss of consciousness. Heart's condition as before—complete arrhythmia.

February 10th.—Patient has been removed by his family.

Remarks.—If the above explanation of the pathogenesis of this case be correct, then we are to believe that a strong nervous or "moral" shock may so disturb the nutrition and innervation of the heart as to cause functional disease of an alarming and protracted, if not permanent character. The supposition is, however, a tenable if not probable one, that in this patient, J—, alcoholism had induced atheromatous changes in the coronary arteries with fatty myocardium. As remarked in a former article, the functional diseases continually trench on the organic, and in the case of the former we are seldom privileged with an autopsy to clear up the diagnosis.

The following case, which came under my own observation while in practice in Canada, is one concerning which there can be no doubt, as the patient eventually recovered.

CASE II.—Heart-strain from overwork.—Patient, S. N—, aged thirty-four, married; farmer; residence, Ship-ton, Canada. Has always enjoyed good health. Parents and grandparents, brothers and sisters free from cardiac troubles.

History of attack.—One year ago (August 1, 1867) while at work in the hay-field mowing heavy grass, and trying to keep up with his hired men, he "felt something give way as if a blood-vessel had burst," became faint, and was obliged to cease work. It seemed, he said, as if his vital forces had left him. It was with difficulty that he walked to his house. From that time the least exertion brought on palpitations, faintness, and some degree of dyspnea. On one occasion it seemed imperative that he should help secure a load of hay, but the attempt to use the pitchfork determined such a heart-pang and such

¹ Lecorché et Talamon: *Études Médicales*, p. 447. Paris, 1881.

oppression that he had to be carried to the house, and he did not leave his bed for several days.

About this time he went to Montreal and consulted the late Dr. Scott, who referred him to me, with the following note: "Mr. N—— has enlargement of the heart from overstrain. I have prescribed for him small doses of digitalis with tincture of chloride of iron. I would advise that this medicine be continued a long time: that he be much in the open air, but he must refrain from work. There is much dilatation, but the heart-muscle will thicken up, and he will be all right by and by if he will be patient and rest for a year or so."

This commended itself as sound advice, and I did little but urge that Dr. Scott's instructions be carried out. Mr. N—— seemed a stout, robust man, with a strong, regular pulse of 86 when not excited. The exertion of ascending a flight of stairs would run his pulse up to 120, with violent diffused throbbing and pain in the precordial region. Never had severe dyspnoea at night. Extremities warm; circulation did not seem to be notably impaired. Auscultation and percussion revealed an increase in the area of transverse dulness; apex in the fifth interspace, and nearly on a line with the nipple. There was no bruit with either sound of the heart, and no pulmonary congestion or œdema.

"At this date" (these notes were written August 3, 1868) "Mr. N——'s condition has materially improved, but he can do no work but light work, such as teaming, doing chores, etc. Is able to superintend his farming operations, has a fair appetite and digestion, sleeps well, and has no heart-trouble as long as he keeps free from excitement and does not exert himself. Takes no medicine."

I have not seen this patient since writing the above memorandum, but have several times heard from him, and understand that he completely recovered from his cardiac malady, being able in a few years to do as much work as at any former period of his life.

Remarks.—This was evidently a case of primitive dilatation of the heart from forcing of the myocardium by overwork; a compensatory hypertrophy followed, which thus far enables the heart well to fulfil its functions. Here, again, the barriers between the functional and organic are trespassed upon, if not overpassed, for dilatation and hypertrophy cannot be said to be strictly normal structural states.

CASE III.—Long-standing dyspepsia, resulting in the symptoms of the forced heart.—Mrs. A. C——, aged sixty-five, a dyspeptic valetudinarian. This patient has been continually under my observation for the past ten years. During all this time, and for several years previous while she was under the care of Dr. Cross, she has suffered from gastric troubles. Has not been altogether incapacitated for housework; appetite has been good, and she has been able to eat and digest sufficient food to prevent emaciation; but her dietary has been necessarily plain, and any overstepping certain limits has always been followed by severe retribution. Attacks of gastralgia, with palpitations, at first infrequent and readily relieved by simple remedies, became more and more frequent and severe, necessitating fasting for a day or two, and very gradual return to solid aliments. Since 1876 these attacks have been chiefly nocturnal, occurring about midnight; have been always attended with eructations of gas and liquids, and (what has distressed Mrs. C—— the most) violent palpitations, or complete rhythmical disorder. These attacks were generally relieved very promptly by a powder of bismuth, calcined magnesias, and charcoal, each ten grains, with a fourth of a grain of opium. The quantity of opium has been gradually increased to a grain.

October 1, 1883.—I have examined the heart of this patient more than fifty times, during the attacks and in the interval, and never detected any murmur, and till recently have always failed to detect any signs of dilatation. At present there is marked evidence of dilatation, an increased area of dulness being discoverable, with apex

displacement. Mrs. C—— now suffers from frequent paroxysms of arrhythmia, with oppression in the precordial region and dyspnoea. There is no lung complication, and nowhere any œdema. The pulse in the interval of the attacks is steady and slow, seldom being more than 75. The arrhythmia is characterized by irregularity in the series of pulsations, with intermissions, pulsations following pulsations in the true style of the *folie cardiaque*, with long pauses between the series of pulsations. Nothing has ever seemed to relieve the patient but remedies addressed to the condition of the stomach. A strict enforcement of rigid dietary rules, with attention to the bowels, has always been followed by good results, with sometimes exemption from the nocturnal attacks of arrhythmia. She now takes at bedtime a little bromide with *chloranodyne* and digitalis; the digitalis is repeated twice during the day, in ten-drop doses of the tincture.¹

CASE IV.—False angina pectoris and palpitations in a hysterical person.—Patient, Mrs. N——, aged thirty-five, widow. Father died of some heart disease at an early age; mother and several sisters died of consumption. Patient is of bad reputation; habits of life for several years irregular; her vicious conduct has impaired the nervous forces. One year ago she had a long sickness which kept her confined to her bed two months; it was pronounced hysteria by the attending physician.

Present condition.—Keeps her bed constantly; says that she is not able to move. When asked what is the matter with her, says that she is in the last stage of consumption; that she is dying of the same disease that her mother and sisters died of. If asked about her appetite, she replies that she has no appetite and has retained no nourishment for four weeks; this account is corroborated by the nurse, who declares that N—— vomits all food and drinks as soon as taken. "They are no sooner down than they are up again." She gets no sleep night or day, according to the statement of her attendants and her own asseveration. There is unimpeachable testimony that she coughs blood and vomits blood every day. She complains bitterly, when undergoing examination, that her chest is sore in every point.

The most thorough examinations, several times repeated, find nothing wrong with the heart and lungs. Her pulse is normal, and she has no fever heat. Despite the fact that she takes no food, she does not emaciate. Tongue is clean, and bowels are regular. Menstruates normally. There is only one diagnosis to make of this case, and that is the one word—made to cover so much ignorance—*hysteria*.

The interesting feature of the case for us now is the fact that she has frequent attacks of palpitations and cardiodynia, during many of which I have been present. The pain is very severe, radiating to all parts of the thorax, though never shooting down either arm; this is simultaneous with the palpitations. The pulse beats from 120 to 140 a minute, and the heart throbblings are intense. There is coldness of the surface and extremities. Acting on the supposition that there was vaso-motor spasm at the bottom of this disturbance, I have lately used nitrite of amyl during the paroxysms, and with

¹ December 3d.—Since writing this report (October 1, 1883) I have again made a careful examination of this patient, and detect a well-marked systolic bruit at the apex, indicating mitral insufficiency; there is also a diastolic murmur at the base. The long-persistent nutritive derangements of the organ, then, have terminated in valvular endocarditis with calcification of the aortic and mitral valves.

Here, then, is a clear case of functional, leading step by step to organic, disease. The concatenation of morbid phenomena is thus indicated by Clifford Allbutt (*Braithwaite's Retrospect*, Part 64, page 72): "1st, dilatation of the right heart; 2d, dilatation of the left heart; 3d, hypertrophy of the left ventricle, or of both ventricles; 4th, chronic inflammation of the aorta and aortic valves; 5th, dilatation of the aorta; 6th, incompetence of the aortic valves; with, 7th, further compensatory hypertrophy of the left ventricle; 8th, loss of compensatory hypertrophy, with consequent rapid failure, and often with consequent mitral regurgitation."

Dr. Allbutt is satisfied, from clinical experience and examination of the dead, that by sheer stretching of the chambers the auricular valves may become incompetent, but oftener the sequence of events is as above described.

In the case of Mrs. C——, the history points clearly to a long series of years in which the strictest examination, repeated almost weekly, failed to discover any signs of structural disease, albeit the functional disturbances were very frequent; when finally, as with progressing age, the failure in the nutrition and innervation of the organ became more decided, dilatation and rhythmical disorder became marked, yet no murmur was audible, till at last a double murmur becomes manifest. Here there is no previous history of alcoholism to explain the endocardial degenerations.

considerable benefit. She also takes glonoine internally, in drop doses three times a day of a one per cent. solution, and this is about all the medicine she takes, owing to the irritable stomach. This patient will in time get well, as she did last year when she had a similar attack.

November 20th.—The above notes were made September 30, 1883. I then considered Mrs. N—the despair of therapeutics, but formed a hopeful prognosis. This patient appears now to be convalescent, and the remedy that is doing all the good—prescribed by an old woman who chanced to visit her—is *Horsford's acid phosphates*. We wonder at the results of metallotherapy (while in our hearts believing it a humbug), and here is something quite as wonderful as anything Mons. Burq has wrought!

†CASE V. *Irritable heart; palpitations; incurable.*—The following case, reported by Dr. J. W. Corson in his "Functional and Sympathetic Affections of the Heart," will come under the head of "Nervous Palpitation."

"A female hat presser, aged thirty-five, unmarried, tall, muscular, apparently healthy, though suffering from want and poverty, in a damp basement, consulted me in 1848 for nervous palpitation of ten years' duration, and for which she bore the marks of counter-irritation while under ineffectual treatment some years previous in Edinburgh. The heart was natural in size and sounds, with a little precordial tenderness to the finger, *painful palpitations* more or less constant, increased by excitement, and accompanied by a smart knocking impulse. Under the use of preparations of iron, Fowler's solution, in combination with vegetable tonics, digitalis, hyoscyamus, conium, valerian, with mild counter-irritation, followed by the external application of belladonna, she continued for two years with slight palliation at times, but no permanent improvement, till at last she grew discouraged and discontinued treatment. A year or so afterward she died somewhat suddenly of pneumonia without affording the desirable opportunity of a post-mortem."

CASE VI. *Cardiodynia, palpitations, and arrhythmia from the use of tobacco.*—From the same paper of Dr. Corson, long out of print, I select the following interesting observation: "A highly intelligent friend, aged sixty-five, stout, ruddy, early married, temperate, managing actively his large business, after premising that he commenced chewing tobacco at seventeen, swallowing the juice, as is sometimes customary, 'to prevent injuring his lungs from constant spitting'—and that years after he suffered from a gnawing, capricious appetite, nausea, vomiting of meals, emaciation, nervousness, and *palpitation of the heart*, dictated to me quietly at his desk, recently, the following story:

"Seven years thus miserably passed, when, one day after dinner, I was suddenly seized with intense pain in the chest, gasping for breath, and a sensation as if *a crowbar were pressed tightly from the right breast to the left, till it came and twisted in a knot round the heart, which now stopped deathly still for a minute, and then leaped like a dozen frogs*. After two hours of death-like suffering, the attack ceased, and I found that, ever after, my heart *missed every fourth beat*. My physician said that I had organic disease of the heart—must die suddenly—and need only take a little brandy for the painful paroxysms, and I soon found it the only thing that gave them any relief. For the next twenty-seven years I continued to suffer milder attacks like the above, lasting from one to several minutes, sometimes as often as two or three times a day or night; and to be sickly looking, thin, and pale as a ghost. Simply from revolting at the idea of being a slave to *one vile habit alone*, and without dreaming of the suffering it had cost me, after *thirty-three years' use* I one day threw away tobacco forever. Words cannot describe my suffering and desire for a time. I was reminded of the Indian, who, next to all the rum in the world, wanted all the tobacco. But my firm will conquered. In a month my paroxysms nearly ceased, and soon after left entirely. I was directly a

new man, and grew stout and hale, as you see. With the exception of a little asthmatic breathing, in close rooms and the like, for nearly twenty years past I have enjoyed excellent health."

CASE VII. *Heart distrain and palpitation from exhausting mental application.*—We cite one or two more interesting illustrations from the same source:

"A friend, distinguished as a divine and author, aged about forty-two, after several years of severe application, in which he habitually studied till three or four o'clock in the morning, was at last greatly incapacitated for a long period by irritable palpitation of the heart. He was most relieved by a succession of blisters the size of a twenty-five cent piece over the heart, and rest with tonics, and at length nearly restored by a tour in Europe, mental relaxation, and more generous diet. Any great mental effort, however, still exhausts his stock of nervous energy and brings on irritability of the heart."

CASE VIII.—"A celebrated Methodist clergyman, of middle age, having by protracted and severe studies brought on irregularity of the heart, was obliged to suspend his labors, and was pronounced a victim to incurable organic disease by good medical authorities. In his retirement he was surprised by the opinion of a shrewd country practitioner that his disease was merely functional, and that he might with proper treatment gradually resume active work; and finding by a little experience the last opinion correct, in a few months he accepted the highest office in the church. He has since labored several years as bishop."

Dr. Corson alludes to the fact, of which I have had personal experience, and seen instances among my classmates, that "medical students exhausted by a winter session are apt to be special subjects of real or fancied irregularity of the heart."

CASE IX. *Arythmia and intermissions from tobacco.*—A. B—, of Salisbury, a cornet-player, consulted me during the past summer for cardiac disorder. When I first examined him, and during two subsequent examinations the heart's action seemed perfectly normal, except that there was now and then an intermission of four or five seconds between the beats, then the pulsations, a little precipitate and violent at first, became regular again. At the fourth visit there was marked arrhythmia of the kind described by Guttman, *i.e.*, after several regular strokes one stroke was omitted, and this was followed by complete disorder in the next series of five or six pulsations. A. B— had been an inveterate smoker, this habit was at once discontinued. He was given digitalis, then cactus and convallaria with, however, little seeming benefit; sleep at night had long been interrupted, and he was now urged to go to bed regularly at nine o'clock, giving up his usual brass band exercise; digestion was disturbed, and an attempt was made to restore this function by dietary hygiene with muriatic acid and strychnia; for the constipation a morning dose of Hunyadi Janos was directed. The disordered rhythm of the heart was only an expression of the disordered rhythm of the other organic functions; the physiological processes had badly adjusted themselves to insalutary conditions, and it required an entire change of scene and of habits, a return to country and to farm life, and an utter abandonment of tobacco, before tolerable health was regained, and even now, when B— is fatigued or excited, some slight cardiac irregularity is noted.

CASE X. *Dilatation, with failing heart from age, successfully treated by cactus grandiflorus.*—This case is imperfectly reported by Dr. O'Hara in *Medical News*, November 10, 1883. The patient, Mrs. L—, was sixty-five years of age, had vertigo, anæmia of the brain, dropsy, etc., all due to failing heart. Dr. O'Hara gave five minims of Parke, Davis & Co.'s fluid extract cactus grandiflorus every four hours to this patient, with marked relief of all the cardiac symptoms and probable prolongation of life.

CASE XI. *Intermittent pulse; dilated and failing heart;*

relief by cactus. (Reported by Dr. O'Hara.)—In a similar case, in which the diagnosis was "dilatation and failing heart, compensation gone by," digitalis, iron, and nux vomica had been given with no effect. The patient became swollen generally, had orthopnoea, suffered very much, heart becoming very intermittent on the least effort. He was going downward daily, and on June 22d ult. the pulse was very intermittent and only thirty-four beats to the minute; patient was very waterlogged in the lungs and over the whole body. Dr. O'Hara obtained a hint from Flint's "Clinical Medicine" as to the efficacy of the cactus in such cases, and ordered five-minim doses of the fluid extract (the preparation of P., D. & Co.) every four hours. In a few days every symptom improved, the dropsy disappeared, and he could lie down to sleep at night. He has been taking the medicine now for five months (the last month fifteen minims *ter die*) with marked benefit; the dropsy has left him; has rarely an intermittent pulse.

Remarks.—The above case is here reproduced, not because it is a well-marked instance of functional disease—there was a soft mitral systolic murmur, and Dr. O'Hara is inclined to regard the valvular incompetency as primary—but because it illustrates the *pulsus tardus* and *intermittences*; how the functional and organic shade into each other; and that practically we have to treat both forms by the same remedies.

CASE XII. *Palpitations from anæmia; relief from iron and glonoine.*—This patient is an elderly woman (past sixty), residing on Unicorn Street, and living in abject poverty and wretchedness. Were it not for the meagre rations which she receives as a city pauper she would starve. She is very anæmic, and has many symptoms which would pass for hysterical.

The notable feature of this case is the frequent attacks of palpitation on exertion; these sometimes come on in the night-time from trifling causes. The nocturnal attacks are generally preceded and accompanied by tremblings of the limbs and coldness of the entire surface, indicating spasm of the vaso-motors. This spasmodic condition of the arterioles is undoubtedly the etiological antecedent of the cardiac disorder.

I am giving this patient perchloride of iron and glycerine, also three times a day one drop of a one per cent. solution of nitro-glycerine; a fifteen-grain dose of bromide at bedtime. I cannot control the dietary of this patient, or procure for her country air and all the benefits of a first-class sanitary residence, therefore I do not expect any lasting amelioration.

CASE XIII. *Dilatation and failure of the heart; palpitations, anasarca; relief from digitalis and convallaria.*—Patient, Miss T—, a maiden lady, aged seventy, residing in High Street. This case is very similar to No. X. (vide supra). There is marked increase of area of cardiac dulness, but no murmur. Pulse generally normal, but exertion brings on palpitations. A notable feature of the case is the anasarca of the lower extremities, which pit, on pressure, as far as the knees. No lung complication, no dyspnoea accompanying the palpitations.

The failure of cardiac power, in fact, the gradual development of the symptoms of the "forced heart," is clearly traceable to the anæmiating and obstructing influence of cancer of the rectum. The case is loathsome in the extreme. The rectum is impacted with cancerous nodules, and there is almost complete constriction and obliteration of its upper portion, so that only liquid feces can filter through. Here, then, we have an agency operating, like a cirrhotic kidney, to interrupt the circulation in quite an extensive mucous tract. This of itself is sufficient to overtax the heart, which, moreover, participates in the general constitutional cachexia and debility. There is nothing to be done but sustain the forces, and make the patient comfortable with anodynes.

I have prescribed digitalis, afterward convallaria, with benefit for the cardiac asthenia and dropsy. The most

good was derived from the convallaria (ten-drop doses of the fluid extract of the flowers) which for some time gave exemption from the annoying palpitations, with marked diminution of the anasarca. The action on the kidneys was quite perceptible.

The preparation of the lily of the valley used was the fluid extract of Parke, Davis & Co., Detroit. I have no experience with any other preparation than that of the Detroit firm, who import all their convallaria from eastern Europe, believing that only the Russian plant is medicinal. Whether this be so or not, we do not seem to have as yet sufficient data for determining. If the European plant possesses medical virtues which the American does not, may we not in this fact find an explanation of some of the failures in the therapeutic employ of this drug which have lately been reported by certain practitioners in this country? It is worthy of remark in this connection that in some instances in which I have known the infusion of the native plant to be used, no results of any account were noted.

CASE XIV. *Irregularity of the heart from lithæmia.*—The following case is reported by Dr. J. M. Da Costa in his "Nervous Symptoms of Lithæmia":¹ "A gentleman, forty-eight years of age, fond of intellectual pursuits, and leading the life of a student in addition to bearing the cares and anxieties of the responsible direction of heavy interests, has been, at least for twelve years, subject to attacks of vertigo which distress him and demoralize him. . . . The attacks are of about a minute's duration; he has had them at night, awakening him out of sleep; they are objective, and followed by dull headache. . . . Irregularity of the heart I found to be very common with him, the pulse some days intermitting every fourth beat, and on others only every twentieth. When these irregularities were most marked he would have rapidly-passing spells of oblivion, during which his mind was a blank, and he would stagger in his gait; he was gloomy and haunted by the idea that he was becoming an epileptic. The intellectual powers were always acute, but long spells of listlessness requiring strong will-power to force himself into exertion were not infrequent. . . . The urine often deposited lithates in abundance; specific gravity 1.020 to 1.024; often oxalates. . . . Slight sallowness of the skin and elevation of the temperature, not exceeding one degree, were occasional symptoms. The joints of the right hand were occasionally tender on pressure, pain in the toes, and so-called rheumatism in the leg were also at intervals observed. Lithæmia existed in the family. The father had suffered from similar symptoms, including the vertigo. A brother had the uric acid diathesis very marked, and had passed renal calculi of uric acid. A system of active exercise, shower-baths, regulated diet, produced very good results; but the cure was completed by a European trip, and the taking, while in Europe, of a course of Kissingen water."

There is no doubt that blood laden with the products of nitrogenous waste is a general irritant and a disturber of all the trophic processes of the economy. There is not one of the organic functions which may not suffer from lithæmia, a condition becoming more and more common as a result of our civilization, and which is, as Dr. DaCosta describes it, "a half gout which does not bring with it the pain, inflammation, and obvious swellings of the gouty paroxysm, but which works more silently, is characterized by the abundance of lithic acid or lithates in the urine, frequently coexists with signs of ill-assimilation of food, and with aches and pains unaccompanied by any perceptible changes of the aching part. Hepatic derangement is also often found, and from this end of the chain the links are stretched through many vague, almost nameless, symptoms to outbreaks of true gout, or to structural change in heart-vessels and kidneys."

That this kind of nitrogenous poison severely affects

¹ American Journal of Medical Sciences, October, 1881, page 315.

the nerve-centres, causing, on the one hand, vertigo, failure of the memory, and mental depression; and, on the other hand, the whole train of symptoms usually referred to spinal irritation (headache, nausea, pains in the upper and lower extremities and sides, gastralgia, dysuria, ischuria, etc.); that it also disturbs the vaso-motor centre, causing general or local spasm of the vaso-constrictors, hence embarrassment of the heart's action and palpitations, we infer from facts that are increasingly numerous. But no theory of this toxic action is complete which does not make account of the influence of lithiasis on the entire cardiac nervous mechanism, a problem for whose solution we have not the data.

Several severe cases of palpitation have, during the past year, come under my observation, which I saw good reason for referring to lithæmia. I have, unfortunately, not been able to follow out these cases.

CASE XV. *Palpitations from loss of blood.*—Mrs. B—, a widow lady, of Newburyport, forty-five years of age, suffered severely from metrorrhagia consequent on change of life, and was rendered thereby very anæmic. For some days after these attacks of flooding she was subject to palpitations, with precordial distress and a diffused knocking impulse of the heart against the chest; there was a bellows murmur and a jerking pulse. After the establishment of the climacteric these symptoms disappeared.

CASE XVI. *Hepatic congestion accompanied by palpitation.*—Dr. Hope "gives a very interesting case of a lady, forty years of age, stout, with intermission, palpitation, and oppression of a heart otherwise natural, and with constipation, succeeded by bilious stools and enlarged liver. Spare diet, and 'active mercurial purgatives, employed almost without intermission for two months, brought off an incredible quantity of dark-green and deep-orange bile.' Suspension of these aggravated the symptoms. In three months she enjoyed 'perfect health.'"¹

CASE XVII. *Uterine disease; palpitation; recovery.*—I am once more indebted to Dr. Corson for the following case: "A lady, twenty-six years of age, having four months previously suffered much in an instrumental first labor, called my attention, in 1850, to palpitation, uneasiness, and a smart, knocking impulse of a heart otherwise healthy, accompanied by dragging pains about the loins. On examination with the speculum the vagina was slightly smeared with leucorrhœal discharge, and the os uteri was prolapsed, swollen, tender, and excoriated. Under the use of occasional applications, with a camel's-hair brush, of a solution of the nitrate of silver of ninety grains to the ounce; vaginal injections of a solution of extract of conium and tannin, alternated with cold water; twenty drops of a mixture of equal parts of the muriated tincture of iron and the tincture of hyoscyamus three times a day in a wineglass of sweetened water; porter, and beefsteak, she gradually recovered her health."

CASE XVIII.—*False angina pectoris in a gouty patient; relief by bleeding and nitrite of amyl.*—The following case from Dr. Lauder Brunton is cited by Huchard in a late number of the *Bulletin Générale de Thérapeutique*: "A gouty patient was suffering from nocturnal attacks of angina pectoris, varying in duration from an hour to an hour and a half, and coming on between two and four o'clock in the morning. During the intervals digitalis, aconite, and lobelia were given without success; during the attack alcohol and stimulants produced little effect; chloroform momentarily calmed the pain. A venesection of three or four ounces and the application of wet cups brought relief. Thinking that the benefit derived from bleeding was attributable to consecutive diminution of arterial tension Brunton was prompted to employ nitrite of amyl, which lowers vascular tension. The patient was made to inhale five or six drops, and immediately with the production of

redness of the face the pain disappeared. Generally the attack of the following night was 'nipped in the bud.' Sometimes a slight paroxysm came on five minutes after the disappearance of the first, but always yielded to the inhalation of a few drops of the amyl. The patient was eventually completely cured."

Dr. Huchard, in commenting on this case, makes this remark: "Lauder Brunton speaks of two kinds of angina pectoris; the one with sudden invasion, which rapidly disappears, whose duration is only a few minutes and is characterized by a sharp pain in the precordial region, the head, and the arm, with a feeling of approaching death; the other, in which the pain may be very intense, but with gradual invasion and rather slow disappearance, whose duration may be from several minutes to half an hour or more, and in which the sensation of approaching death is less accentuated, or even absent. It is useless to remark that the characters assigned by Brunton to the second variety of angina are those which I have attributed to the false anginas of the arthritic."

PREVENTION OF PUERPERAL INFECTION.

BY HENRY J. GARRIGUES, A.M., M.D.,

VISITING OBSTETRIC SURGEON TO THE NEW YORK MATERNITY HOSPITAL.

MANY years before Pasteur, by his experiments with microbes, founded the germ theory of zymotic diseases, and before Lister, applying the theory to the treatment of wounds, revolutionized surgery, the theory that puerperal fever is due to infection was propounded, and a specific preventive treatment instituted to guard against it. In my paper on "Lying-in Institutions," published in the "Transactions of the American Gynecological Society," in 1877, I showed that as early as 1847 Semmelweis, of Vienna, acting on the principle that puerperal fever was due to infection with cadaver poison, introduced in one of the two departments into which the large Viennese Lying-in Hospital is divided, the use of chlorine-water for disinfecting the hands before any vaginal examination was made, and that he thereby brought the mortality down to a comparatively low figure.¹ Since that time the theory, divested of its exclusiveness, has constantly gained ground, but it was especially after Listerism had begun its triumphant march through the world, that a methodical antiseptic treatment was used as a preventive of puerperal fever. As far as I can find, this was first done in 1870 by Stadfeldt, of Copenhagen,² who used carbolic acid, and soon similar measures were more or less adopted everywhere. I myself have used carbolic acid regularly for the last eight years for my hands and instruments, for vaginal injections twice daily during the first week after delivery, for washing out the uterus when indicated either as a prophylactic or a curative measure, and for covering the genitals during the lying-in period.

So pleased was I with this treatment, that when I was appointed Visiting Obstetric Surgeon to Maternity Hospital I followed it there, and am convinced that it was of some value both in preventing and curing disease, but nevertheless it was far from satisfying the demand for an efficient antiseptis. In private practice it is comparatively easy to avoid infection if we take care not to cause it ourselves. A hospital is the true place in which to try the value of an antiseptic, and I doubt there are many places which present the conditions for a more crucial test than our New York Maternity Hospital, an institution which, properly speaking, does not exist at all except in so far that it has a medical board of its own, while in every other respect it is only a department of Charity Hospital—a large general hospital in which all diseases, medical and surgical, are treated. Seventy women or more, expecting to be confined within a period

¹ Corson, in Boston Medical and Surgical Journal, February 1, 1854, page 22.

¹ Semmelweis: Die Ätiologie, der Begriff und die Prophylaxis des Kindbettfebers, pp. 61-63. Wien, 1861.

varying from four months to a few days, occupy two "waiting wards." When labor pains set in, they are transferred to the "pavilions," two small wooden buildings, each of which contains two large and two small wards, but one of the large and two of the small are used as dormitories for the pupils of the training school for nurses. As soon as feasible the patients are therefore returned to the main building and placed in the so-called "convalescent ward," which accommodates twenty-four patients. When at times there reigned much disease in the pavilions, the whole service was transferred to a ward in the main building, where the results became still worse until the pavilions had been disinfected and could be occupied again.

As everybody would expect who knows how dangerous a place a general hospital is for lying-in women, the mortality has at all times been much greater than nowadays we find it in real lying-in asylums. Since the maternity service was brought in connection with Charity Hospital the mortality has been :

Year.	Deliveries.	Deaths.	Percentage.
1875	570	15	2.67
1876	536	20	3.73
1877	480	32	6.67
1878	225	7	3.11
1879	254	11	4.40
1880	149	8	5.37
1881	382	9	2.36
1882	431	14	3.25 ¹

While some of these deaths are attributable to diseases for which the hospital is not responsible, the great majority were the effect of hospitalism.

The present year will show as bad a record as any on the preceding list. Of 345 women delivered during the first nine months of the year, 30 have died, and, in order to avoid the appearance of throwing blame on others, I will add that I was myself on duty during the first three months, in which 108 women were delivered, 11 of whom died.

The bad condition of the hospital becomes still more apparent if we examine the frequency of disease after delivery. It used to be rather an exception than the rule to see a perfectly normal lying-in period. During the six months from October 1, 1882, to March 31, 1883, in which I was on duty last, 192 women were delivered, and 46 of these, or almost 1 in 4, were seriously sick, 39, or almost 1 in 5, of inflammatory puerperal diseases.

The special diseases are seen by the following table :

A. *Inflammatory puerperal diseases.*—(a) Diphtheritic vulvitis, colpitis, or metritis, 19 cases (3 of these developed peritonitis, 4 died). (b) General peritonitis, 10 cases (3 of them had diphtheritic inflammation, 7 died). (c) Metritis, 10 cases (6 of them had dissecting metritis,² none died). (d) Perimetritic inflammation, 2 cases (local peritonitis, parametritis, none died). (e) Erysipelas, 2 cases (1 with mammary abscess, 1 with diphtheritic inflammation of the genitals, both died). (f) Pleuritis, 1 case. (g) Mammary abscess, 5 cases (1 developed gangrenous erysipelas and died).

B. *Non-inflammatory puerperal diseases.*—(a) Shock after Cesarean section, 1 case (died). (b) Hemorrhage, 2 cases (died). (c) Cerebral hemorrhage during delivery, 1 case (died). (d) Mania, 1 case (recovered). (e) Uræmic coma, 1 case (died). (f) Eclampsia, 1 case (developed diphtheritic inflammation, recovered).

C. *Non-puerperal disease.*—1 Double pneumonia before delivery, 1 case (died).

When I again went on duty on October 1st of this year, the condition of the hospital was at its worst, nine women having died during the last month, and half a dozen

seriously sick, puerperæ being left over from the preceding service, one of whom succumbed a few days later.

In the meantime, bichloride of mercury had begun to be praised as an antiseptic in surgical and obstetric practice. I therefore laid a detailed plan for its use in Maternity Hospital, and the Commissioners of Public Charities and Correction kindly furnished the apparatus and appliances requisite to carry it out. But not trusting in the sole effect of a yet untried antiseptic drug, I adopted several other measures, each of which may have contributed somewhat to the splendid results obtained.

The service was divided into two departments, one for the well, the other for the sick patients, each of which had its separate doctors, nurses, and utensils. Two large wards with accommodation for nine patients each, and a small one which shelters six, besides the delivery-room, were reserved for the first class; a large ward and two tents were destined for the sick puerperæ.

Rapid alternation in the use of the wards was insured by only keeping each patient eight days in the pavilions, and transferring her on the ninth to the convalescent ward. When the last patient in a ward has reached her ninth day, it is under all circumstances emptied, and if for some particular cause it is deemed desirable to make an exception from the rule, so as to keep a patient a few days longer in the pavilions, she is transferred to the ward used for the last confined women.

If a patient, either in the pavilions or in the convalescent ward, shows any sign of infectious disease, she is immediately transferred to the department for the sick puerperæ.

The doors between the wards were locked, and the chinks filled with tow and pasted over with paper. Doors leading to water-closets were furnished with springs, and the windows in the water-closets nailed so as to prevent them from being closed.

As soon as a ward is empty it is fumigated with sulphur—twenty pounds to the larger and fifteen pounds to the smaller wards. After that the windows are kept open day and night. The floor is scrubbed with soap and water, and subsequently with a solution of bichloride of mercury (1 to 1,000), and so is every piece of furniture, bedsteads, chairs, etc., and the beds are provided with fresh bedclothes and new straw.

In all the wards are placed large demijohns, filled with a solution of bichloride of mercury (1 to 1,000), which for brevity's sake is called *the solution*. For the hands it is used undiluted, or when the weather is cold, with the addition of a small quantity of hot water. For the patients it is mixed with equal parts of water, the temperature of which is regulated according to circumstances, so as to obtain a lukewarm solution for the skin, the vagina, and the uterus when the sole object is to clean them; or a very hot one for arresting or preventing post-partum hemorrhage.

When a patient is brought to the delivery-room she is given an enema and a bath as heretofore, but after that her abdomen, genitals, buttocks, and thighs are carefully washed with lukewarm solution (1 to 2,000). At least two quarts of the same fluid are injected into the vagina by means of a fountain syringe, consisting of a glass bucket, a rubber tube, and a straight glass tube, and in protracted labor these injections are repeated every three hours. The rubber sheet covering the delivery-bed is washed with the undiluted solution immediately before every delivery.

In order to limit the danger of infection by vaginal examinations as much as possible, no nurses are allowed to make any except the one in charge of the waiting ward and the head nurse in the pavilions, and even these are directed not to repeat them more frequently than they need for notifying the doctors. The latter are urgently requested not to introduce their finger into the womb in common cases, but to be satisfied with such information as is derived from abdominal palpation and the examination of the part presenting at the external os.

¹ These figures are taken from Dr. W. R. Gillette's Report for 1875, published in the American Journal of Obstetrics, Dr. Kitchen's and Dr. Estabrook's Reports to the Commissioners of Public Charities and Correction, and for the last two years from the written records of Charity and Maternity Hospitals.

² On this disease, see my articles in The New York Medical Journal, December, 1882, vol. XXXI, p. 387; Archives of Medicine, April, 1883, vol. ix, No. 2; and THE MEDICAL RECORD, December 15, 1883, p. 664.

At the beginning of a labor doctors and nurses wash their hands in the solution, using soap and large, stiff nail-brushes; and if more than one patient is in labor at a time, the same precaution is taken before going from one to the other. Besides this, the hands are held for a minute or more in the warm solution, kept for that purpose in a particular basin at the side of the bed, every single time before the genitals are touched, and no other lubricant is used than the fluid adherent to the fingers, except in operations in which the whole hand has to be carried into the genitals, or the forceps is to be used. Then I use glycerine with bichloride of mercury (1 to 2,000), which I prefer to the carbolized oil or vaseline heretofore in use, because the glycerine itself possesses antiseptic properties which are still enhanced by the addition of the bichloride.

When the foetus appears at the vulva a piece of lint, soaked in the solution, is applied to it, and kept there all the time, in order to prevent the surrounding air from being pumped into the vagina by the alternate progression and recession of the presenting part. After the expulsion of the child the genitals are kept covered with a similar compress.

The placenta is expressed by Credé's method, so that the accoucheur need not introduce his fingers inside the rima pudendi: and if in exceptional cases it becomes necessary to do so, the vagina is washed out with the solution; otherwise not.

Acting on the same principle, intra-uterine injections are only used when the hand or instruments have been introduced into the interior of the womb, or in case of the birth of a macerated child.

I never allow any part of the placenta or the membranes to remain in the womb. With good antiseptic treatment the introduction even of the whole hand into that organ is of no account compared with the danger of hemorrhage and septicaemia by leaving any part of the secundines behind.

The intra-uterine injection is given immediately after the removal of the secundines; a large amount of fluid is used (from two to six quarts), and it is taken so hot that the hand can just be held in it. For its administration I have had made a curved glass tube, fifteen inches long, a little over a fourth of an inch wide, with a large opening at the end and eight side-openings, all of which have well-rounded edges, and are placed on the last four inches of the tube. It differs from Chamberlain's by its small calibre, its open end, and the greater number of lateral holes. The small calibre I prefer because it enables me to use the same tube any time during the first two weeks, even after considerable contraction of the internal os has taken place. The opening at the end I take to be necessary in order to be sure to wash the fundus thoroughly, and the larger number of side-openings insure the same effect on the side walls of the uterus. The perforated part of the tube being only four inches long, it is entirely within the internal os, which prevents a premature escape in the cervix.

Before the tube is introduced into the womb the vagina is thoroughly washed out, and during the passage from the latter to the womb the solution is kept running, so as to avoid the introduction of any septic substance from the vagina to the womb, and insure the exclusion of air.

When used immediately after confinement this tube is introduced between two fingers held in the cervix. Later in the lying-in period, if symptoms of inflammation are developed I place the patient on her back on a table and introduce Cusco's speculum, in order to be able to inspect every part of the vagina and the vaginal portion of the cervix, and be sure not to overlook any diphtheritic infiltration, the disease which has caused the greatest ravages at Maternity Hospital. A bed-pan is then shoved under the patient, and the tube introduced through the speculum after careful disinfection of the vagina. If no indication is found for intra-uterine treat-

ment the douche is only applied to the vagina. After this little digression we will return to our supposed case of normal labor.

After the expulsion of the secundines the patient is washed with the solution and the vulva covered with a *dressing* consisting (1) of a piece of lint, six by eight inches, folded lengthwise, so as to be three inches wide; (2) outside of that a piece of oiled muslin, nine by four inches; (3) outside of that a large pad of oakum; and (4) the whole is fastened with four pins to the binder in front, and behind by means of a piece of muslin eighteen inches square, and folded diagonally so as to form a kind of boat, five inches in width, for the reception of the other pieces of the dressing.

This dressing is put on with the same care as we dress a wound after a capital operation, and renewed four times in the twenty-four hours, twice by the day-nurses and twice by the night-nurses. At the same time the parts nearest the genitals are washed with the solution. Before each washing the nurses disinfect their hands as before labor. Any substance, such as cotton, lint, etc., brought in contact with the genitals is beforehand thoroughly soaked in the solution. No vaginal injections are given, except in the rare cases in which the lochia become offensive. By the effective antiseptic treatment at the entrance, preventive injections become superfluous, and thus one great source of infection is avoided.

Four times a day the floors of the wards are sprinkled with the undiluted solution. In order to avoid the introduction of infection by visitors coming from people suffering from diseases which might endanger our patients, these are not allowed to receive any visitors as long as they are in the pavilions, a rule which even applies to clergymen, except in danger of death. Baptisms are performed outside the wards. It goes without saying that the doctors and nurses employed in the pavilions are forbidden to enter the wards of Charity Hospital or the dead-house. Unfortunately, a similar restriction in regard to hospital wards cannot be laid on those in the convalescent ward, since they are employed in Charity Hospital simultaneously.

The severe exclusion of strangers was deemed necessary as long as I did not know how much I could rely on the dressing. Since I have seen its admirable effects I have ventured to let a few doctors, under my personal control, visit the wards and witness operations, and it is my hope that in the course of time the institution may be used for clinical instruction on a larger scale, and thus a very serious lacuna in our medical education be filled.

The use of carbolic acid is restricted to the disinfection of metallic instruments, which is done with a five per cent. solution, all metals being corroded by the bichloride solution, and consequently weakening it.

The local effect of the dressing is to impart a whitish hue to the skin, a bright scarlet color to blood, and a yellow color to abraded surfaces. Mucous membranes lose somewhat of their slipperiness. The lochia are kept uncommonly sweet. Very few patients have complained of a little smarting, and in one there appeared a pustular eruption on the thigh near the genitals, both of which conditions were easily remedied by the application of a little glycerine. In no case has the dressing been abandoned. In one case a papular erythema appeared on the chest and above the knees, but as I have observed similar eruptions before the use of the bichloride, I do not think there was any connection between the two; so much less so, as the erythema disappeared in two days, although the dressing was continued. In no case has there been any general symptoms attributable to the drug. Some of the nurses complained in the beginning of sore hands, but inunction with glycerine obviates that.

All linen coming from sick women is immersed for at least one hour in the undiluted solution.

In the convalescent ward the dressing is continued as long as the patients are kept in bed. As soon as their

condition warrants it, commonly between the tenth and the fifteenth day after their confinement, they are discharged. Protracted cases of a non-puerperal character are transferred to Charity Hospital, and no waiting-women or helpers are allowed to sleep in this ward. By these different means the air is kept as fresh as possible, and room is obtained for new patients coming up from the pavilions; but it is very much to be regretted that lack of room does not permit a regular alternation, as in the pavilions, and that, on account of ventilators communicating with other wards, it is not practicable to fumigate this one. In this ward, as well as in the waiting ward, hands and instruments are disinfected as in the pavilions.

The effect of the described treatment has been wonderful. As by magic all trouble disappeared. Ninety-seven women have been delivered since its introduction, and not only has *none of them died*, but there has *scarcely been any disease* among them, and especially no trace of diphtheritic inflammation, by which we used to be persecuted. Up to this day we have only had six sick women: two had local perimetritic inflammation, three metritis, and one eclampsia. None of them, with the exception of the latter, has been seriously ill, and yet we have had two cases of podalic version and a craniotomy. Of the six patients, three only had a rise in temperature; the eclampsia case had none, and two of the patients with inflammation had none; and yet the presence of the inflammation was sure enough as proved by the other symptoms, spontaneous pain, sensitiveness to pressure, and exudation. This lack of fever I can only explain by the perfectly aseptic condition in which the genitals were kept by the dressing, and in this respect it seems that our results are better than those observed elsewhere. Kehler, for instance, claims only to have reduced the number of his febrile patients from two-thirds to one-third of the whole number of confined women. The pavilions are scarcely recognizable. Where we used to have offensive odors, feverish, prostrated or despairing patients, overworked nurses and despondent doctors, the air is pure, the patients look well, their temperature is normal, the nurses are cheerful, and the doctors happy.

I am particularly indebted to the house-surgeon, Dr. H. A. Leipziger, who with great energy and intelligence carried out my plan in all its details, and instructed the nurses in their part of the work, and what he began has been faithfully continued by his successor, Dr. D. P. Pease.

The bichloride of mercury presents great advantages over carbolic acid. First of all, it is a much more reliable disinfectant; next, it is not only free from odor itself, but it is an excellent deodorizer; it affects the skin of the accoucheurs and nurses much less; and even from an economical standpoint the new treatment is a great improvement. The oiled muslin costs $3\frac{3}{4}$ cents per day for each patient, and the lint a little over $4\frac{3}{4}$ cents per day,¹ but even this expense is a trifle compared with the cost of the quinine, morphine, and whiskey used in treating puerperal inflammations—not to speak of the great saving by the cheapness of the bichloride compared with carbolic acid.

In private practice I use the same treatment with slight modifications, substituting cotton for oakum, using the common rubber fountain syringe, or, if the latter is not at hand, even a Davidson's syringe, and having the dressing renewed only three times a day. Instead of the glass tube, which is easily broken in the obstetric bag, I use a tin tube with a large opening at the end. It has one advantage over the glass tube, viz., its flexibility, that allows it to bend according to circumstances, which I have found useful in cases of abortion. Metal is indeed corroded by the bichloride, but in private practice, where instruments are not used so often, where they

are less frequently exposed to contact with septic matter, and where it is easier to disinfect them, this is of less importance than in a hospital.

It might be objected to this paper that the time in which the treatment has been tried is too short to form a final opinion of its value, but the change in the condition of the patients and the wards before and after its adoption has been so sudden and surprising that it must convince everybody who knew the institution before. Secondly, the same good results can only be obtained by the constant attention to all the details of the treatment, and since that depends on the good will and the firm conviction of many individuals, and the uninterrupted supply of the materials used for the dressing, there is always some danger that puerperal infection may again find its way to the hospital. Finally, reports from other places coincide with my experience.¹

In conclusion I would state that, although I am convinced that the bichloride of mercury is in itself a better antiseptic than carbolic acid, I attribute our success in a great measure to the dressing, by which this drug is applied in such a way that no air gains access to the genitals without passing through the disinfectant.

137 WEST TWENTY-SECOND STREET.

SEVERE AND EXTENSIVE INJURY OF FORE-ARM, WITH RECOVERY.

By MEIGS CASE, M.D.,

WASHINGTON, D. C.

THE extension of the railway system and corporate neglect to provide substitutes for hand-coupling has already created an army of men, who, with absent and crippled fingers, hands, and arms, are silent witnesses of the hardships of an indispensable vocation. A statistical exhibit of the number and character of these injuries would be interesting and valuable. The unpromising appearance of these cases usually suggests amputation, and it is believed that the undefined limitations of surgical enterprise too often permit it.

The illustration shows one of these injuries, as it was presented for treatment:

Thomas Lane, twenty-eight years of age, engaged in coupling a locomotive to a "gondola," was caught by the heavy iron bar, which was driven through his left arm, fracturing both radius and ulna, about one and one-half inch in front of the elbow-joint. An additional fracture of the radius in its middle third completely detached a four-inch piece, which lay transversely across

¹ Ad. Olivier, Tarnier's assistant, in *Annales de Gynécologie*, November, 1882, vol. xvii., p. 338; A. Toporski, Fritsch's assistant, in *Centralblatt für Gynäkologie*, September 1, 1883, vol. vii., p. 553; Wiedow, Hegar's assistant, *ibid.*, September 15, 1883; P. Bröse, Schroeder's assistant, *ibid.*, September 29, 1883; Paolo Negri, of Novarra, in *Bulletin général de Thérapeutique*, October 30, 1883, p. 373; Kehler, of Heidelberg, *Centralblatt für Gynäkologie*, November 3, 1883, p. 709. It is Tarnier who first introduced it in obstetric practice, and that before it was used in surgery; but he uses it only during labor and in sick puerperæ.

¹ A piece of oiled muslin, one yard wide, five yards long, costs \$1.70; a pound of lint, fourteen inches wide, seven yards long, costs 75 cents.

the wound. Two other small pieces of loose comminuted bone were removed. The soft parts were crushed through near the radial attachment of the biceps, and nothing remained unsevered but a few fibres of the supinator longus and the extensor radialis longior. The weight of the forearm, thrown upon these thin attachments, and a band of skin less than two inches wide, permitted the most extraordinary downward displacement of the nearly severed arm. The patient said that he feared it would "drop off" before he got home. The median nerve was torn half across the ulnar artery, and the soft parts adjacent were crushed, and the wound filled with soot. The borders of the wound were twenty-three inches in length, and extended nearly around the arm, terminating at points opposite and not to exceed two and one-half inches apart. The brachio-radial artery was, however, uninjured, and he had a good pulse at the wrist.

I determined at once to give the patient the benefit of this fortunate circumstance, removed portions of crushed tissue, and carefully replaced the parts, and secured them by interrupted sutures. The whole was held in position by lateral splints of flannel and plaster-of-Paris, and the whole arm laid upon a pillow and covered with yeast poultices.

The venous hemorrhage was considerable during the first two days, and extensive swelling occurred with *sloughing* of the injured muscular tissue and bulging of the under lips of the wound. By the free use of nitric acid, this process was facilitated and controlled. There was no sloughing of the skin, and union by first intention took place in nearly one-third of the suture. At the expiration of ten days, the sloughs having disappeared, and the swelling greatly diminished, drainage-tubes were inserted from bottom to top, running through the centre of the arm. An opening was made for this purpose on the lower side, about three inches in front of the olecranon, and the entire arm surrounded by plaster-of-Paris bandage, with the exception of a half-inch opening for the drainage-tubes at the most dependent part.

The patient began to go about, and at the expiration of three months recovered, with some paralysis of the forearm and ankylosis of the elbow-joint; but he is able to carry a pail of water or handle a shovel and hoe as well as ever. The ankylosis at the elbow is slight, and could be easily broken up and motion restored.

The above illustration is taken from a photograph, and was made by direction of Dr. D. I. Huntington, Acting Surgeon-General of the United States, who has kindly suggested this publication.

November 7, 1883.

SIXTY BUSHELS OF PAMPHLETS, advertising a patent medicine, were received in the Boston Post Office last week, and were found, on examination, to contain also a circular advertising a Kansas lottery.

SOME FACTS REGARDING LARGE INFANTS.

By W. P. BRECHIN, M.D. (HARV.),

BOSTON, MASS.

MRS. A—, primipara, aged twenty-two, five feet three inches in height, weight 127 pounds, was taken in labor November 1st, at 11 P.M. The pains continued with great violence until 1 P.M. the following day, when I was summoned.

On my arrival I found the patient very much exhausted and pains very weak. On examination I found the occiput presenting to the left, and the os fairly dilated. After waiting about two hours, and there being little or no advance, the forceps were applied, without ether and with but little difficulty. After a great deal of traction had been made, continuing for about one hour, I succeeded in delivering her of a very large male child, which I then estimated would weigh about 15 pounds. On the following day I went prepared to take the exact weight and measurements. The result was as follows: Weight, 18 pounds 6 ounces; length, 22 inches; biacranial diameter, 9 inches; circumference of thorax, 15½ inches; circumference of breech, 14 inches; circumference of thigh, 8 inches; circumference of arm, 5 inches; occipital mentalis diameter, 16½ inches; occipital frontalis diameter, 15½ inches.

The size of children at birth has been greatly exaggerated. Some are said to have weighed 24 and even 30 pounds, and to have been three feet in length. Cazeau states that in three thousand cases the largest weighed 10 pounds. Lachapelle states that of four thousand the largest weighed 12 pounds. Baudelocque records one that weighed 12¾ pounds; Merriman one weighing 14 pounds; Crofts one of 15 pounds. Owens records one weighing 17 pounds 12 ounces; extreme length, 24 inches.

Cazeau was called in consultation with Dr. Rimbault, and with great effort, after turning, succeeded in delivering a woman of a dead child, which weighed 18 pounds, its extreme length being 25½ inches.

Dr. Meadows reports a case in which the length of child was 32 inches and the weight 18 pounds 2 ounces, the child surviving but four hours. Dr. Rice, of Springfield, reports a case where the child weighed 20 pounds 2 ounces; extreme length, 23¾ inches; mentalis occipital circumference, 16¾ inches; frontalis occipital, 16 inches; around shoulders, 20¼ inches.

Dr. A. P. Beach, of Seville, O., who delivered the Nova Scotia giantess of a male child, reports the dimensions as follows: weight, 23¾ pounds; height, 30 inches; thoracic circumference, 24 inches; breech circumference, 27 inches; head circumference, 19 inches; foot, 5½ inches in length. Six years previous she was delivered in London of a still-born child weighing 18 pounds and 24 inches in length.

As to the cause of children attaining such gigantic proportions, we can only say that it is a "*lusus naturæ*." Some have attempted to explain it by supposing that the child is carried beyond the normal period of gestation, but this view does not seem to be borne out by facts, for in these cases the child usually assumes pigmy proportions. Reasoning from analogy, I can see no reason why we cannot have giants in foetal life as well as giants and liliptians in adult life. When we see children of such gigantic proportions born we are almost forced to think that craniotomy and embryotomy are often performed when there is no necessity for so doing. Why one physician should have so many craniotomies and embryotomies while others pass through a large and life-long practice without encountering a single case is, to me, inexplicable. I am acquainted with a physician who during his first year of practice had no less than six craniotomies, and if his cases have increased in the same ratio he must have ere this performed an astounding number. It seems as if there was a wanton destruction of infant life. If there is no deformity of the pelvis I

am borne out by facts when I say that any child varying from six to twenty pounds can be forced with safety through the pelvis.

The fact of not administering ether in this case was a great advantage to me, as the patient was able to give me a great deal of assistance. She made a good and rapid convalescence, the only complaint being a numbness alternating with pain in the lower limbs. The child at the time of its birth was apparently dead, but by the use of resuscitating measures it began to breathe. It continued cyanotic and died at the end of three weeks. These large children rarely do well; the greater proportion of them are dead when born, or survive but a short time.

A CASE OF CONGENITAL GOITRE CURED BY A SINGLE APPLICATION OF MERCURIC BINIODIDE.

By J. C. WORTHINGTON,

CAPTAIN AND ASSISTANT SURGEON U. S. ARMY.

I FIRST saw the patient, S. D. B.—, a well-developed male infant, July 26, 1883, six hours after birth. The mother, a healthy woman, native of Prince Edward Island, and for a year past resident on her husband's rancho on the Uncompahgre River, Colorado, had had a slight goitre for over two years, the swelling having first been noticed during her previous pregnancy. The family was much alarmed at the appearance of the child's throat.

On examination I found a marked goitrous swelling, soft, but not fluctuating; on the right of the trachea. The tumor was as large as a hen's egg. I advised that nothing should be done until the child was three months old, when I would attempt to cure it by an external application, which I thought would not be advisable before that time.

I did not see the child again until November 12th, when it was brought to me by the mother for the treatment that I had promised. I found him a well-nourished baby, healthy in every respect except the deforming tumor on the right side of his throat, which had increased with his growth, and now filled the whole space between the chin and sternum on that side. His mother stated that the tumor now interfered with the child's breathing when he lay on his back. The flattening of the crown of the head, mentioned by Aitken, was now well marked. I confess it was with some misgivings that I prescribed for the child the treatment mentioned in Aitken's "Practice of Medicine," as having been attended with such wonderful success in India. I ordered the following:

R. Mercuric biniodide gr. x.
Lard 3 j.
M. and S. Apply as directed.

I directed as follows: At ten o'clock A.M., on a bright sunny day, rub well into the skin over the whole tumor a lump of the ointment of the size of a filbert. Then hold the child, with the tumor exposed to the sun, at a closed window, as the weather was cool, for half an hour, then for an hour in front of a fire. At 2 P.M. of the same day repeat the application, and expose to the sun and fire as before.

On November 28th the child's mother brought him to me—cured. She stated that the treatment had been carried out as directed on the 17th, except that the exposure to the sun in the afternoon had been for less than thirty minutes, on account of its being so painful to the little patient. That he had had much pain and cried a great deal the following night; that the skin had become very red and had peeled off wherever the ointment had touched it; that she thought the next day the swelling seemed smaller, and on the 20th—three days after the application—the tumor was almost gone, and had grown smaller ever since until it entirely disappeared. When seen November 28th—eleven days after the application—there was no evidence of cutaneous irritation, and the

thyroid gland was just perceptible to the touch, as in a normally formed infant. The cure was complete. No salivation or other indication of constitutional effects of mercury occurred.

CANTONMENT ON THE UNCOMPAGHRE, COLORADO,
December 1, 1883.

Progress of Medical Science.

THE TREATMENT OF FÆCAL FISTULA OF INFLAMMATORY ORIGIN.—Dr. B. Riedel has lately recorded (*Centralbl. für Chir.*, No. 14, 1883) two cases of fæcal fistula of inflammatory origin treated with success by operation. Fæcal fistula of such origin, being of much less frequent occurrence than fistula resulting from strangulated hernia, has not, he points out, engaged the attention of surgeons so much as the latter variety. Dr. Riedel states that in neither of his cases could the starting-point of the lesion be clearly made out. As there was no indication of previous intestinal disturbance, it cannot be assumed to have been typhlitis. Although the view of a glandular origin might be opposed by the fact that no lesion was observed on the lower limbs or on the genitals, still Dr. Riedel is disposed to think that the abscesses in these two cases, as in many instances of acute psoas abscess, really started in suppuration of some pelvic glands; and it is suggested that this glandular mischief may have been started by abrasion or fissure of the mucous membrane of the anus. Such pelvic abscess may burst at an early date into the gut and the pus be discharged by the rectum, whilst the passage of fæcal matter into the cavity of the abscess may be prevented by a valvular disposition of the margins of the intestinal opening. In the first case, the fistula had at one time remained closed for two years, although during this period there remained a large opening in the wall of the intestine. This opening must during this time have been hermetically closed by the firmly applied superjacent skin. In dealing with the fæcal fistula of inflammatory origin Dr. Riedel exposes the seat of perforation, sets free the affected portion of intestine so as to be able to drag this to the surface, and then closes the orifice by sutures. He doubts whether the peritoneal cavity was opened in either of his two cases. No loops of smooth intestine were observed. Probably around the seat of the fistula in each case there had been formed, between the intestine and the abdominal wall, thin membranous adhesions which allowed the perforated portion of intestine to sink back into the abdomen, and yet prevented the passage of fæcal matter into this cavity. In Dr. Riedel's cases, the conditions for the success of his operative treatment were favorable, as the adhesions between the intestine and the anterior abdominal wall were of slight extent. In an instance of wide union of these structures it would be necessary to have recourse to resection of the perforated portion of intestine.

NERVOUS CORYZA.—Dr. Joseph Herzog relates the case of a young lady, of nervous temperament, and coming from a nervous family, who suffered nearly every day from sudden paroxysms of sneezing. The nasal mucous membrane became swollen and the nose was stopped up; there was a serous, and sometimes later, a purulent discharge from the nostrils, lachrymation, and diminished sense of smell: the face became flushed, there was frontal headache, ringing in the ears, and sometimes a burning sensation in the throat and external ear. The entire attack lasted only two or three hours, and was usually shortened in its duration if the patient placed herself with her back to the fire. During the menstrual periods the attacks were more severe and the discharge from the nose very profuse. Nothing abnormal was to be discovered in the throat or nose during the intervals between the attacks. The injection of a weak soda solution into the nostrils was ordered, while internally arsenic, in increasing doses,

was exhibited with good effect. The author observed the same condition, which he denominates *rhinitis vasomotoria*, in a child two years old. The child usually took a nap in the afternoon, lying in a hammock in the garden, and whenever he did so, would be awakened by a strong fit of sneezing accompanied by a nasal discharge, lachrymation, and all the other symptoms of severe coryza. The attacks lasted about two hours, and did not occur if the child was put to sleep in the house. Dr. Herzog regards the affection as a vasomotor neurosis, and thinks that it arises in individuals of nervous disposition in consequence of some peripheral irritation, which, by reflex influence, excites the vasomotor nerves of the nasal cavity to greater activity. As a consequence, there is increased afflux of blood to the parts, giving rise to swelling of the mucous membrane and increased secretion. The author states incidentally that hay-fever is also a nervous coryza, and that the asthma accompanying it is of reflex origin. The treatment consists, locally, in the application of any of the commonly employed remedies. Internally, the author recommends the vasomotor remedies, aqueous extract of ergot (9 to 13 grains per diem in pill form), atropine, and especially Fowler's solution (3 to 10 drops three times a day). Other drugs may be used, as quinine, cannabis indica, iron, zinc, bromide and iodide of potassium, and the salicylic preparations. Sea-baths, cold water applications, and electricity may sometimes be of service.—*Allgemeine Medicinische Central-Zeitung*, October 24, 1883.

CHANGES IN THE INFERIOR VENA CAVA OCCURRING WITH CIRRHOSIS OF THE LIVER.—The study of oedema of the subcutaneous connective tissue in cirrhosis, and the thereby induced belief that this oedema could not be explained wholly by the mechanical conditions existing in the liver, led Dr. de Giovanni to examine particularly the condition of the vena cava in this affection. These investigations disclosed the fact that the oedema in question was owing chiefly to disease and consequent disturbance in function of the vena cava ascendens. He found peri- and endo-phlebitis, thickening of the adventitia, hypertrophy of the entire wall of the vessel, and increase in size of its lumen. In one case of cirrhosis of the liver in which, notwithstanding there was meteorism and marked ascites, no oedema was present, he predicated the absence of disease of the vena cava, and the correctness of his assertion was confirmed at the autopsy.—*Centralblatt für Klinische Medizin*, October 27, 1883.

TUBERCULOSIS WITH ASTHMATIC SYMPTOMS.—Certain forms of tuberculosis are, according to Professor Germain Sée, difficult of diagnosis because of the fact that the most prominent symptom is the frequent occurrence of attacks of dyspnoea simulating very closely ordinary asthma. The recognition of this form of phthisis is all the more important, since between true asthma and tuberculosis there exists an antagonism by reason of the atrophy of the alveoli and destruction of the capillaries consequent upon emphysema, thus opposing a barrier to the development of tubercle in the lungs. The following are the chief points of value in the differential diagnosis: True asthma occurs usually at night, manifesting itself in sudden oppression of breathing, difficult inspiration, and sibilant expiration, and at the termination of the attack there is a peculiar expectoration. The return of the paroxysms in each individual is always accompanied by phenomena of a remarkable sameness and peculiar to that patient. These precursory phenomena are most frequently a nasal catarrh with the anomalous sensations resulting from it, tympanitic swelling of the stomach and intestines, diuresis, or a change of character in the individual, with an inaptitude for work. Nothing of this kind is seen in the dyspnoea of tuberculosis. Almost always the attack is brought on by some exertion, quick walking, going up-stairs, rapid muscular movements, or the effort of severe coughing, or repeated vomiting. It occurs usually in the daytime, the patient

seeks repose and generally obtains relief by lying on the back. There is no whistling expiration, the respiratory movements are increased, but at times there is no such marked distinction. The pseudo-asthmatic paroxysms may be clearly intermittent, may occur at night, and may be followed by catarrhal symptoms. The liability to error in such cases is all the greater, since the general condition of the patient is usually so good as not to give rise to a suspicion of tuberculosis, and it is only by studying the general and physical symptoms with great care that we are able to arrive at a correct diagnosis. The asthmatic form of tuberculosis is of very slow growth. The general symptoms are slight and the patients often preserve their digestive functions unimpaired for years. They have but little fever and only a moderate cough; the expectoration, though muco-purulent, is not abundant. The general condition, indeed, is so good that it is often an occasion of surprise to find at the apices the evidences of sometimes pretty extensive tubercular infiltration. The prognosis is fairly favorable, yet, as in other forms of tuberculosis, it should be based partially upon the state of the digestive organs.—*Revue Médicale*, October 20, 1883.

ACTION OF TOBACCO ON THE TEMPERATURE AND PULSE.—Dr. Troitski has made a number of observations upon the effects produced on the temperature and pulse by smoking. He found that in every case, varying according to the condition of the individual, there was an acceleration of the pulse rate and a slight elevation of temperature. If the average temperature of non-smokers were represented by 1000, that of moderate smokers would be 1,008, and while the heart in the former case was making 1,000 pulsations, in the latter it would beat 1,180 times. It is in the latter effect that he thinks the danger of tobacco smoking is manifested.—*Journal de Médecine de Bruxelles*, vol. lxxvii., 1883.

THE TECHNIQUE OF MASSAGE.—Dr. Benster summarizes the method of practising massage, followed by the French, as follows: 1. *Effleurage*, gentle friction, consists in making long, gentle, centripetal strokes along the course of the veins and lymphatics with the oiled hand. The pressure is intermittently firm and gentle, so made as to produce a sort of passive peristalsis. 2. *Massage à friction*, the rubbing stroke. This is accomplished by making elliptical strokes perpendicularly to the long axis of the limb with the finger-tips of one hand, while the fingers of the other hand pass from above downward, parallel to the axis of the extremity. A subdivision of this class is the *massage par ondulation*, as used by Laisné in lumbago. 3. *Pétrissage*, kneading, is made always in a direction from the periphery toward the centre, and in such a way that the morbid tissues are seized by the hand, raised up and kneaded. This is employed in oedema of the skin, infiltrations into the subcutaneous connective tissues, and on muscles which have lost their pliability through infiltration, inflammation, or contractures. 4. *Tapotement* consists in a tapping or beating of the diseased parts by the finger-tips, the hollow hand, the side of the hand, the fist, the percussion hammer, or a little rubber ball fastened to a piece of whalebone. This is employed chiefly in neuralgia.—*Wiener Medicinische Wochenschrift*, October 27, 1883.

DIRT SIMULATING ICHTHYOSIS.—Dr. C. Mettenheimer saw an old maiden lady, aged eighty-seven years, whose foot and outer side of the thigh were covered with brown, polygonal, horny scales, from a half to one inch in thickness, resembling the hide of an alligator, and which might well be taken for ichthyosis. They were, however, composed of nothing but old, so to speak, crystallized dirt, which, as the reporter learned, had been accumulating for twenty-five years. Warm water, assisted by a weak solution of caustic soda, brought about a cure. The scales dropped off and disclosed to view the perfectly normal integument.—*Schmidt's Jahrbücher*, October 17, 1883.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, December 29, 1883.

THE REPORT OF THE SURGEON-GENERAL OF THE U. S. MARINE HOSPITAL SERVICE.

THE annual report of the Surgeon-General of the Marine Hospital Service for the year 1882-3, is a larger document than usual, and contains a good deal that is suggestive and interesting.

We learn that during the past year 40,195 persons received relief from the Service, 13,356 being in-patients. The number of deaths was 502, or somewhat over one per cent. of the total, and less than four per cent. of the in-patients. In the list of diseases we observe the prominence of syphilis, of which over three thousand cases are reported, with a mortality of only nine. The working sailor appears to have a low mortality-rate, if we exclude the losses due to accident and shipwreck. One-half of the deaths are due to general diseases, including especially phthisis and the fevers. The remainder are due to various local diseases, especially those of the respiratory, vascular, and digestive systems. Out of 502 deaths, four per cent. were due to injuries.

The Marine Hospital Service embraces a *clientele* of about 100,000 seamen, who pay a tax of forty cents a month. This tax gave an income of \$415,945.80 last year. The expenditures, on the other hand, were \$469,966.21, this sum including, however, about \$35,000, which was expended for extraordinary repairs and alterations.

This amount of money, though very large, is not excessive, but the contrary, when it is considered that the patients are treated at over ninety different ports and in more than a dozen different hospitals. A bill is now before the House to reduce the hospital tax to twenty cents. If this is done, Congress must make some provision to prevent a deficit. In fact, if the policy is continued of using the officers of the service, paid by the sailors, for purposes of national quarantine, then the Government ought to pay its share.

One is especially struck with the rapid increase in the annual amount of medical and surgical work. This has increased from ten thousand cases annually, a few years ago, to the present number, forty thousand. At such a rate, the Service will have in ten years to enlarge greatly its working capacity. We are of opinion, however, that in time there will be a more discriminating limitation of those who should pay hospital dues. In justice it should only include those seamen who have no legal residence or home, who are truly wards of the nation. Travelling

workmen on the river vessels really seem to have no more claim on the tax-money system than travelling salesmen.

The demand for entrance into the Marine Hospital Service is yearly becoming greater. Thirty-seven applications were made for position as assistant-surgeon last year. Nineteen candidates were examined and five passed. The examination of pilots for color-blindness has continued and there is now no objection to this useful practice. The Surgeon-General wisely urges that the examination should be made to cover acuity of vision and also the sense of hearing.

The subject of the physical examination of seamen previous to shipping is also touched upon, and the recommendation is renewed that there shall be a compulsory physical examination of all of this class. This is of especial importance to those who are about to go on long voyages. The examinations thus far made show that about four per cent. of those applying for shipment are unfit for active service.

Dr. Hamilton devotes a few pages to the subject of national quarantine. His views in brief are that our country needs a maritime quarantine, and that the United States can and should render service in making this efficient. The duty of the general Government ends, however, under existing laws, with maritime quarantine. Local port sanitation and internal quarantine belong to the States and municipalities. An account is given of the quarantine work of last summer and the claim that the exertions of the Service were largely instrumental in keeping out yellow fever are no doubt correct.

The usual tables showing the medical work of the year are given. These could be studied to much better advantage if the statistics were tabulated as a whole as well as by districts.

To the report proper is appended a considerable number of medical and surgical contributions illustrating the work of the medical officers. There are also elaborate reports of the Mexican-Texas Yellow Fever Epidemic, by Surgeon Robt. A. Murray, and of the Florida Epidemic, by Dr. Jas. S. Herron.

FALSEIFYING THE RETURNS.

WE have been asked to refer to a practice which has long existed among our medical charitable institutions, and which is fast doing injury to them in the eyes of the public. It is that of "falseifying the returns," so as to create the impression that a greater amount of work is done than is actually the case. For example, a dispensary reports that it has treated ten thousand cases during a single year. The facts are that the real number treated is about one-fourth or even one-half less. It is a very common custom in dispensaries to give a patient a ticket which lasts a month; when the month is ended, if the patient is still under treatment, a new ticket is issued and the patient is counted again. The number of cases treated is also increased (on paper) by other means. The object of these practices is twofold. The public is appealed to with additional force by these deftly manipulated statistics. For to say that "twenty thousand poor sufferers have been substantially relieved" is more emphatic than to speak of only ten thousand. Again,

the charities of the city receive pecuniary aid from the city in proportion to the amount of work done, and the more patients the more money.

We do not mean to charge the managers of our dispensaries with intentional dishonesty. The practices alluded to are common to nearly all, and are doubtless known by the city authorities. It would be hard for one institution to attempt reform if the others failed to follow its example. None the less is the practice a discreditable one, and we earnestly trust that there will be an attempt made to end it. We might add here that charities other than medical do substantially the same thing, and exaggerate their work for the sake of engaging the public sympathy and getting more of the public money.

VETERINARY MEDICAL ORGANIZATION.

FOR the past year there has been a great deal of organizing activity among American veterinarians, and State Veterinary Associations have been formed in nearly all of the Western and Middle States. This activity is the result largely of the enterprise of a very wide-awake Chicago quasi-professional veterinary journal. The organizing work progressed very smoothly until it reached this State, since which time there has been trouble. It appears that the Western veterinary editor wished to create a new State association here under similar auspices with those of other States. Unfortunately, there was a State society already existing; a feeble thing to be sure, but with enough vitality to protest against extinction. The result is, as we are informed, that two State societies now nominally exist, with reciprocal ill-feeling between them.

Nor is this all. The movement to organize veterinarians assumed finally a national aspect, and a call was issued to form a United States Veterinary Medical Association. This call was responded to and a society has been established, as was noticed in *THE RECORD*. It happens, however, that a national association of the same kind was already in existence, and had been for a number of years. The fact that this society was ignored has naturally produced much dissatisfaction.

As matters now stand, therefore, American veterinarians, though organized, are not harmonious, the factions being led by rival journals. There is doubtless some blame attached to both parties; that of the West has been somewhat obtrusive and uncomprising, while the older party in New York was a poor specimen of the kind.

We trust that the agitation will result eventually in improving the status of comparative medicine. There is not yet any great opportunity for organizing useful scientific societies, since the total number of educated veterinarians in the United States is probably less than a thousand.

GERMS AND GERMICIDES.

OUR forefathers of the good old fox-hunting and gourmandizing kind lived upon high mutton, venison, and birds, and devoured millions of germs in their well-ripened cheese. The same happens to a greater or less extent now. It could not have been the port wine and brandy

which killed all these germs, for some forms of bacteria will live in alcohol for months. They must have been destroyed by the acid gastric juice which these active, out-door-sport-loving squires were furnished with. It is well known that food in a state of partial decay has this process arrested in the healthy stomach, and indigestion goes on as sweetly as if the food had been very fresh. Now, if putrefaction is caused by bacteria, either the pepsin must attack and digest them, or the acids of the stomach kill them. It is supposed that the germs of typhoid fever and cholera are not generally operative until they reach the lower portions of the small intestine, where the secretions become alkaline. In short, that most healthy persons will escape the effects of these poisons, when taken in their food or drinking-water, provided the stomach is in full digestive operation, or the quantity of the living poison be not so great that some of it escapes into the small intestine before it can be killed or digested. Cholera- or typhoid-water or milk drunk into an empty stomach by thirsty souls is especially dangerous. It has required Koch's almost unrivalled skill to prove that cholera bacteria, which have long been known, are merely more abundant in the small intestine and only penetrate farther into its coats than ordinary bacteria.

Nedwetsky proved, as far back as 1872, that cholera-bacteria were not killed by quinine, camphor, carbolic acid, calomel, or chloral; that opium, nux vomica, and chloroform destroyed them very slowly, while the dilute acids, sulphuric, nitric, and muriatic, decompose them very quickly, as did tannic acid, sulphate of iron, and chlorine water; also corrosive sublimate, bromine, and iodine. But perhaps milder remedies may have the same effect; at least one per cent. of tartaric acid will kill the yeast plant, but allow bacteria to thrive, while a five per cent. solution will allow mouldy growths to appear; or a stronger solution will kill both these and bacteria. It is known that yeast plants, moulds, and bacteria feed upon each other, but that bacteria will destroy or eat up all the others. One part of corrosive sublimate in 20,000 of water will kill bacteria in ten minutes; 1 part in 5,000 is a certain disinfectant, and of course as safe as stronger solutions of the milder tartaric acid. But sulphurous acid, generated by burning sulphur, which is the most commonly used disinfectant, requires thirty minutes to kill bacteria, and their spores will sometimes live for ninety-six hours. A five per cent. solution of carbolic acid requires twenty-four hours, and a three per cent. will not kill them at all. A five per cent. solution of chloride of zinc requires one month, and they have even been found alive at the end of that time. Iodine, 1 part to 5,000 of water, destroys them; and bromine, 1 part to 1,500 of water. Chlorine water requires two days, and a five per cent. of chloride of lime, ten days. Benzoic acid, benzoate of soda, chlorate of potash, and quinine, which have been vaunted as specifics, have little or no effect upon them. Bacillus spores will germinate after lying for months in absolute alcohol, but a small quantity of acid will kill them. Carbolic acid is not an acid, but an alcohol. Alkalies rather seem to favor their growth. The oils of mustard, peppermint, turpentine, and cloves, even in dilute solutions, have a restraining influence upon bacterial development. We understand that experiments

are being made with turpentine as a disinfectant and curative in diphtheria. The simple mineral acids may be better than the muriatic tincture of iron, and tartaric acid may turn out as good as any; but large doses of pepsine, with dilute muriatic acid, are not to be forgotten.

News of the Week.

NORTHWESTERN MEDICAL AND SURGICAL SOCIETY.—

At the regular annual meeting of the Northwestern Medical and Surgical Society of the City of New York held on December 19, 1883, the following officers were elected for the ensuing year: *President*—Dr. Ed. C. Harwood; *Vice-President*—Dr. T. H. Burchard; *Secretary and Treasurer*—Dr. J. Henry Fruitnight.

LAPAROTOMY FOR HEMORRHAGE IN TUBAL PREGNANCY.—Dr. C. K. Briddon of this city writes: Dr. J. C. Reeve of Dayton, O., has drawn my attention to the following extract from the *Amer. Journal of the Medical Sciences*, April, 1879: "Dr. Veit (*Deutsche Zeitschrift für Prakt. Med.*, No. 49, 1878) says that about one-fifth of the cases of hæmatocele are due to rupture during tubal pregnancy, and that the latter is more frequent and capable of a more favorable prognosis than is generally supposed. In the rare cases in which an early diagnosis of tubal pregnancy can be made expectant treatment is indicated. When rupture occurs an attempt must be first made to arrest the hemorrhage by external means; and as a last resource, laparotomy must be performed, although it does not afford a very good chance. The method of arresting hemorrhage will vary in different cases. Sometimes it will consist in the application of sutures, sometimes in removal of the sac, etc. Dr. Veit performed laparotomy on a moribund patient to arrest the hemorrhage produced by rupture in tubal pregnancy. The Fallopian tube was tied, the sac sewn to the lower angle of the wound, and plugged with salicylized cotton-wool. After two days, plastic peritonitis set in, of which the patient died sixty-four hours after the operation.—*British Med. Journal*, Feb. 15, 1879."

ARMY MEDICAL DEPARTMENT.—The following gentlemen have passed the Army Medical Board: William D. Dietz, of New York; William Stephenson, of Maine; John L. Phillips, of the District of Columbia; William C. Borden, of the District of Columbia; Guy L. Edie, of Virginia; William L. Kneedler, of Pennsylvania; Charles S. Black, of New York; Alonzo R. Chapin, of Illinois; Walter R. W. Fisher, of Virginia; Adrian S. Polhemus, of New York; Reuben L. Robertson, of Virginia; Edgar A. Mearns, of New York; William D. Crosby, of New York; Charles M. Gandy, of New Jersey, and James E. Pilcher, of New York.

THE NEW YORK SKIN AND CANCER HOSPITAL is trying to secure a piece of land for its suburban convalescent department. We trust the managers will be successful in their benevolent object. In this connection we would say that it has been asked why the dermatologists have taken up the management of cancer, which belongs to surgical pathology. One of our New York dermatologists, in his work on "Skin Diseases," has said

that "the dermatologist should interfere in carcinoma only in those cases which have the character of epithelioma, and are easily destroyed by caustics." It is certainly true that patients with cancer should have the attendance of general surgeons and practitioners.

DR. MILTON JOSIAH ROBERTS, of New York, was tendered a brilliant reception by Dr. Wm. H. Daly, of Pittsburg, Pa., at the latter's residence, on Thursday, December 20th. There were in attendance a large number of representative medical gentlemen.

MEDICAL TRAMPS IN BOSTON.—At a meeting of the Suffolk District Medical Society, Dr. H. I. Bowditch requested the privilege of occupying a few moments for the purpose of warning the profession against a band of medical tramps which was infesting Boston and its suburbs, and by every expedient seeking to obtain pecuniary aid from physicians. One of these impostors had suffered an amputation of the thigh, wore an artificial limb, professed to be a graduate of Harvard, and the son of a physician, and presented plausible testimonials recommending him to the profession. The letters of commendation were found by Dr. Bowditch to be forgeries, and the man himself is a swindler. Another member of this band of conspirators is a young man who is elaborately dressed and makes a favorable appearance, and whose habit is to call at the physician's house when the doctor is away. He represents himself to be the son of a celebrated physician of New York, who is a very intimate friend of the physician at whose door the young man is standing. He further states that he has been robbed of all his money and desires to borrow a sum, generally from three to five dollars, to aid him in reaching his home. Upon being informed that the doctor is not at home, his eyes fill with tears and he appears to be in great distress of mind, and at length endeavors to borrow the sum required of the person who has come to the door. If he does not succeed in this ruse, he asks the time at which the doctor will return, and is very particular *not* to return at that time. Another is a man of swarthy complexion, who pretends to be from India, but is probably an arrant cheat.

FIRE IN THE WARD'S ISLAND LUNATIC ASYLUM.—The towers, spires, roof, attic, and part of the fourth floor of the new east wing of the City Asylum for the Insane, on Ward's Island, were destroyed by fire December 21st. No patient or employé was hurt, and the loss, about \$20,000, is not covered by insurance. But for a westerly wind the greater part of the seven buildings of which the asylum consists would probably have been destroyed, because the fire apparatus on the island was out of order, the water-supply inadequate, and there was gross blundering in the transmission of intelligence of the fire to this City. The fire started in the attic, from what cause is not known. There were 90 patients in the burning building, but they were safely transferred. Subsequently all the patients in the eastern buildings, 497 in all, were transferred to the western wings. Some one blundered in that the provisions for suppressing the fire were so inadequate. The responsibility appears to be chiefly upon the Commissioners of Charities and Correction, who for eight years have known the defects without remedying them.

Reviews and Notices.

A] TREATISE ON SYPHILIS IN NEW-BORN CHILDREN AND INFANTS AT THE BREAST. By P. DIDAY, ex-Surgeon to the Hospital de l'Antiquaille, Lyons. Translated by G. WHITLEY, M.D. With Notes and Appendix by F. R. STURGIS, M.D., Professor of Venereal and Skin Diseases in the New York Post-Graduate Medical School; Surgeon to the Venereal Division of Charity Hospital, Blackwell's Island, etc. New York: William Wood & Co. 1883.

THE publishers are certainly to be congratulated upon their choice of M. Diday's scholarly treatise for this (October) number of their Library of Standard Medical Authors. They have, moreover, been especially fortunate in having secured the services of Dr. Sturgis to edit this American edition, who, it is needless to state, has admirably performed a somewhat thankless task and added materially to the value of the book. The *ensemble* of the issues of this Library is far too well known to call for further mention at this time. In this particular instance, however, we desire to call attention to the elegant colored lithograph which faces the title-page. A single artistic and carefully executed plate like this is worth a thousand of the fearfully and wonderfully made cuts with which our present literature is so largely besprinkled.

The book proper is primarily divided into five parts: etiology, description, prognosis, medico-legal bearings, and treatment. The subdivisions under each are exhaustive; and each point is discussed vividly, earnestly, and thoroughly, while a wonderful profusion of illustrative cases is advanced. The author succeeds in clinching the reader's attention at the start, and deftly holds his interest to the end with that graphic art and delicate cogency so characteristic of the French, the essence of which the translator has for the most part very happily caught.

In the Appendix, Dr. Sturgis expands, in a masterly manner, two of the more important points: "First, the question of the viability of children born with the taint of hereditary syphilis, the mortality which occurs among them, and the causes which produce death; and, secondly, the accidents known under the name of syphilis hereditaria tarda, or late congenital syphilis."

We have no hesitation in ranking the work among the most suggestive and valuable books of the year.

HEMIATROPHY OF THE TONGUE IN LOCOMOTOR ATAXIA.—Dr. Gilbert Ballet writes in *Le Progrès Médical* of October 27, 1883, concerning a symptom of tabes dorsalis, mentioned by few writers, yet of frequent occurrence according to his experience, viz., hemiatrophy of the tongue. The atrophy is in every case unilateral, although the other signs of locomotor ataxia are bilateral and often nearly symmetrical. There is a marked diminution of size on one side, whether right or left, and on this half there are numerous ridges and grooves, giving a peculiar appearance to the organ. There is sometimes a slight trembling with fibrillary contractions. The tip of the tongue is sometimes deviated slightly toward the atrophied side. This hemiatrophy interferes very little with speech, and not at all with mastication and deglutition. In most of the cases observed by the author there was paralysis of some of the eye-muscles or atrophy of certain muscles of the extremities. A fact that renders this symptom of special importance is that it is among the earliest manifestations of tabes dorsalis. It may, in fact, exist at a time when the other signs are either very obscure or have not yet made their appearance. When, therefore, unilateral atrophy of the tongue is encountered, one ought at once to think of the possibility of locomotor ataxia.

Reports of Societies.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Special Meeting, December 21, 1883.

S. O. VANDER POEL, M.D., PRESIDENT, IN THE CHAIR.
THE PREVENTION OF PUERPERAL INFECTION.

DR. H. J. GARRIGUES read a paper on the above subject. (See page 703.)

The discussion was opened by Dr. R. A. MURRAY, who was Dr. Garrigues' immediate predecessor at Charity Hospital. He had been especially interested in Dr. Garrigues' good report, because, despite all the precautions used while he was in charge of the service the mortality from puerperal fever was nearly eight in one hundred cases of confinement, and the form of fever seen was very similar to that met with in Bellevue Hospital. Puerperal peritonitis was seldom seen, but puerperal diphtheria occurred very frequently, usually beginning at the vulva and extending up the vagina, but in only a few cases was it seen in the uterus. It was also seldom ushered in with marked symptoms. The ward was disinfected from time to time, but it was finally given up, and when Dr. Garrigues began his service it was a new ward so far as confinement cases were concerned, and probably that fact influenced the results somewhat at least, yet he questioned whether so good results would have been obtained without the practice of antiseptic midwifery. Dr. Murray thought it would be difficult to carry out in private practice the details given by Dr. Garrigues, but the material part could be adopted by thorough disinfection of the napkins, and washing out the vagina before and immediately after delivery, and treating all lacerations with bichloride of mercury solution or iodoform. He had seen cases in which the parts had been actually cauterized with carbolic acid, and yet the diphtheritic exudation returned as quick as ever after the removal of the eschar. It might seem that such details as had been given by Dr. Garrigues are meddlesome and not warranted, but in hospital practice they must be adopted in order to prevent the spread of puerperal fever, although he thought it was unnecessary to adopt them in private practice.

DR. W. GILL WYLIE said the paper by Dr. Garrigues confirmed the views which he expressed in a paper read about six months ago, and he was thoroughly in favor of the use of antiseptics, even in private practice, as it is well known that the most successful obstetricians have, occasionally at least, had cases of puerperal fever develop in their practice. Since he began their use in Bellevue Hospital he had employed them in private practice; that is, had caused the vagina to be washed out with a solution of carbolic acid—usually one to thirty—the body of the patient washed with the same solution, all the bed-linen, two sets of blankets, and napkins to the number of thirty at least, all carbolized, and in only a single case had he seen any signs of septic fever, and that was one in which he used forceps in a dry labor. Now he would use the bichloride of mercury solution in place of carbolic acid.

In all that had been said recently on this subject he thought sufficient stress had not been placed on *perfect drainage*, and especially after abortion. This can be secured by dilating the cervix, and, if necessary, a drainage-tube should be used.

DR. W. R. GILLETTE thought all must admit the importance of the subject under discussion, and while there might be some difference of opinion concerning the exact methods by which the principle was to be applied, it was scarcely worth while to dwell upon them. With regard to the compress presented by Dr. Garrigues, however, he was unable to understand how it could be of special service with the woman lying in bed; certainly it could not

be kept in close coaptation with the parts, and therefore sufficient space would be left for the entrance of germs. Still the theoretical objection should not weigh much against the results of actual experience in its use. He sincerely hoped the good report made by Dr. Garrigues would be continued, but his experience in the same hospital allowed him only to hope for its continuance. He thought the fact that Dr. Garrigues' service began in a new ward, as mentioned by Dr. Murray, may have had considerable to do with the immunity from puerperal fever, and he also wished that Dr. Garrigues had gone back to 1875, and given the statistics for that year, when the service was transferred from Bellevue.

At the time the change was made forty women were transferred and only one suffered from puerperal fever, and the prophylactic measures were simply cleanliness, bathing with carbolic-acid water, and keeping them as far apart as possible in the lying-in room. Of the six hundred and thirteen women confined during that year, only three had puerperal fever. He thought this record was even cleaner than that given by Dr. Garrigues, and it was obtained by perfect cleanliness.

DR. A. S. HUNTER was in accord with the author of the paper, as to the value of cleanliness and the use of antiseptics, and there was no question but that better results had been obtained since their adoption than were secured before special antiseptic measures were introduced. He was in accord with Dr. Gillette concerning the compress to be applied to the vulva, and thought the rubber muslin would be liable to get folded so as to bring a waterproof surface against the vulva and do more harm than good. Moreover he thought it impossible to keep it in close position with the external genitals. Besides he thought clots would be retained in the pad, and in that way the door opened for the entrance of germs. He also preferred to use Dr. Lyman's silver tube rather than the glass tube, and preferred Davidson's rather than the fountain syringe. He thought that carrying out the suggestions made by Dr. Garrigues was not at all difficult. In private practice he would reject the compress, would use vaginal injections, and in cases of septicemia, intra-uterine injections, and in addition would have a napkin, partially saturated with carbolic or bichloride solution, laid against the external genitals.

DR. S. BARUCH congratulated the Society on having had presented to it a paper in which the praises of antiseptic injections in normal labor had not been sung. He had attended about nine hundred cases of labor, had met with very many complications, and had had only one death preceded by febrile symptoms. He had not used prophylactic injections very much until Dr. Wylie read his paper, and since then had followed the directions given, but his experience in their adoption had been somewhat singular, as in each of the six cases in which he employed them fever developed, undoubtedly due to septic process, occurring from the fifth to the eighth day after labor. Dr. Baruch then spoke of the objections to antiseptic prophylactic injections, such as disturbing the woman, displacement of clots, and thus opening avenues for auto-infection, tearing of recent adhesions, etc., all of which had been seen in hospital practice. He believed that simple cleanliness before, during, and after labor would do all that can be done to render labor safe, and that, if it was necessary to meddle, the introduction of iodoform pencils into the uterus or vagina was the least harmful probably.

DR. F. V. WHITE referred to his experience in Bellevue Hospital thirty years ago, when it was the practice to wash out the vaginas of all lying-in women every morning with liquor sodæ chlorinatæ. Certainly in this respect Bellevue had priority. He cited an instance where obscure symptoms of puerperal fever developed in one of the patients, and she was transferred to another ward. The vaginas of the remaining women were washed out, he continued in his service, yet no other case appeared.

The patient removed died about two weeks afterward and autopsy revealed extensive peritonitis. He had endeavored to have his private patients use vaginal injections on the second day after confinement; sometimes had succeeded, and many other times had failed. Of the two thousand cases of labor which he had attended he had not lost any patients from puerperal fever. He had not been able to remove the placenta with the ease mentioned by Dr. Garrigues.

DR. J. P. GARRISH had attended four thousand cases of labor in forty years, and had had only two cases of puerperal fever. He never allows a nurse to attend who has recently been in attendance on a case of any contagious disease. He thought intra-uterine injections should be avoided in normal labor. The duty of the physician is to assist nature when she is wrong. He had had only private practice, to be sure. Dr. White had said that Bellevue deserved credit for being the first to wash out the vaginas of lying-in women; so also it had the reputation of being the place where the greatest number of women died when the lying-in service was there.

DR. WHITE said they did not in his time.

DR. GARRISH objected to applying anything like a compress to the external parts.

DR. J. C. PETERS believed that bichloride of mercury solution would prove a more successful germ destroyer than any agent which has been used.

DR. GARRIGUES said his statistics were based upon experience in the *old* wards and not the new one first occupied. He emphasized the necessity of adopting precautionary measures in private practice. He also stated that the compress had been found by actual measurement to be adapted to the distance between the thighs as the woman was lying in bed; that it was applied by the nurses with the exactness with which any surgical dressing was applied, and that while it was not absolutely air-tight, it was as much as could be used with the presence of a lochial discharge. Dr. Garrigues then read from his paper where he had made a quotation from Dr. Gillette's report, and it appeared that he had included the year 1875, but the figures varied considerably from those given by Dr. Gillette. A metallic tube cannot be used if the bichloride solution is employed. He would never use intra-uterine injections except for cause, and for him that cause would be fear of entrance of septic material, as in manual or instrumental interference, or the presence of a dead child. He thought that under ordinary circumstances vaginal injections may have done a great deal of good in hospital practice, although he had given them up because he had reached the same result by other means. In private practice he thought there was no danger in their use, and at the same time he thought no harm would follow if something else was substituted, but if not, they should be resorted to. The dressing recommended rendered vaginal injections superfluous, and the nurses had nothing to do with the genitals of the patients. Of course, cleanliness is proper, but it is not sufficient. He agreed that labor is a normal process, but a woman confined in a hospital is in an abnormal situation, and statistics have established the fact that antiseptics have markedly reduced the mortality in lying-in hospitals.

The Society then adjourned.

AN AGED PARENT AND A LONG UMBILICAL CORD.—Dr. F. W. Putnam, of Binghamton, N. Y., writes: "On December 5, 1883, I attended Mrs. B—, aged thirty-seven, in her second confinement. Cranial presentation, first position; labor normal, terminating three hours after my arrival. The umbilical cord was thirty-one and one-half inches long, and had a knot in it eight inches from the body of the child. The child, a boy, is alive and doing well. The father is seventy-seven years of age!"

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, December 20, 1883.

FORDYCE BARKER, M.D., LL.D., PRESIDENT, IN THE CHAIR.

THE PROGRESS OF BIOLOGY IN EUROPE.

DR. C. HEITZMAN spoke on the above subject and said that in 1872 and 1873 he published a series of new observations concerning the structure of the single elements of which the entire animal body had been supposed to be composed. He did not expect the immediate approval of scientists, nor had he received it, but within the last two or three years very great progress had been made in this direction. A little more than one year ago he published a book in which these new views were set forth, and it was met by warm friends and bitter enemies. Some of the criticisms deserved attention; others were the outbreak of personal enmity. The theory was that so-called protoplasm, which had been thought to be structureless, has, at a certain stage of development, a well-marked reticular structure; that the nucleus, if hollow, has in its interior a reticulum; that the so-called nucleoli were thickenings at the points of intersection of these delicate fibres, formerly called granules; that the locomotion observed depends upon contraction of one part and expansion of another. Quite recently a large number of German microscopists had observed changes in the reticulum of the nucleus, and special reference was made to the writings of Strasburger Flemming and others.

Dr. Heitzman said he was aware that the existence of this reticulum had been denied by some microscopists in this country. One gentleman in Philadelphia had denied its existence because he was unable to see it.

The second point in his theory was that the basis substance seen between these so-called cells is endowed with all the properties of living matter due to the presence of a reticular structure identical with that seen in the protoplasmic bodies. Dr. Heitzman then gave an account of his method of procedure to demonstrate this point, namely, by experiments with cartilage, and best shown when a slight amount of inflammation is obtained with calcareous deposition in the basis substance.

Having proved this point satisfactorily to himself he then advanced the view that instead of the body being built up of cells, these so-called cells are uninterruptedly connected with each other by delicate fibres of living matter and the whole body is of the general structure of the amoeba. Dr. Heitzman then spoke of Stricker's views concerning the reticulum of the protoplasm, nucleus, and basis substance, and said that he had admitted there is no difference whatever, with reference to capacity for producing life, between the basis substance and the cells. "Why use the term cell, then?" asked Dr. Heitzman. To which Stricker replied that the word should not be altogether abandoned, and he continued to use it in order that he might be understood by those whom he addressed. Concerning the exact function of the basis substance there was some difference of opinion between S. Stricker and Dr. Heitzman.

The speaker then directed attention to the changes in view concerning the essential nature of inflammation which necessarily accompanied his theory, and discussed at some length the views held by Recklinghausen and Cohnheim concerning the origin of pus-cells. Dr. Heitzman then spoke of the structure of epithelia and the views of Ranvier, who admitted that they are connected with each other by what he calls "filamentous connections," without committing himself to any theory concerning their essential character.

Passing from this point the speaker touched upon the question of tuberculosis and defined tubercle to be a vascular inflammatory product, and the reason why new vessels do not form in the little nodules is because there is not sufficient living matter for their reproduction. He

rejected Koch's theory of the bacillus as a cause of tubercle, and maintained that tuberculosis can be produced artificially by the introduction of various substances into the tissues of animals. Special reference was made to the work of Spina, and to the fact that he (Spina) had introduced sterilized lycopodium seed into the abdominal cavity of a guinea-pig, and ten or twelve days afterward found tubercles in the liver, kidneys, and intestines, which on microscopical examination were found, each one of them, to contain a few lycopodium seeds. He regarded Koch's bacillus as the product and not the producer of tubercle. In conclusion, Dr. Heitzman spoke briefly of the theory of constitutional conditions being diagnosed by microscopical examination of the colorless corpuscles of the blood.

DR. W. H. WELCH remarked that Dr. Heitzman had chosen for his theme a very broad subject, but he had confined his remarks to a small department of biology, namely histology, and chiefly to one corner of histology, the morphology of the cell.

In 1873 Dr. Heitzman promulgated his doctrine regarding the structure of cells and of the animal body. The main features of this doctrine were, first, that the cell-substance is pervaded by a network of fibrils; second, that the nucleus and the nucleolus are simply condensations of this network, accumulations of living matter identical in structure with that in the cell-body, and, third, that this network of living substance passes out from the apparent cell-boundaries and pervades the basement substance and connects the cells with each other. The human body, therefore, is essentially a large amoeba.

As regards the first point Dr. Welch remarked that before Dr. Heitzman's publication a differentiated structure of protoplasm had been described. After Max Schultze, Brücke, and Beale, in 1862, had overthrown the views of Schwann and Schleider as to the vesicular structure of the cell, protoplasm was usually described as granular or hyaline. In the bodies of some cells, however, particularly of ganglion-cells, certain details of structure had long been made out by Stilling, Schultze, Arnold, and others. For certain cells of amphibia Leydig, in 1865, described a reticulated structure of the protoplasm. The first, however, to ascribe a fibrillated structure to cells in general was Frommann. In 1866 he described in neuroglia-cells, not first in ganglion-cells as Dr. Heitzman had quoted him, fibrils proceeding from the nucleoli through the cell-bodies into the surrounding substance. In 1867 Frommann extended this observation to many other kinds of cells and claimed a fibrillated structure as a general characteristic of cells. Flemming is therefore right, in his important work on cell-substance, in granting to Frommann, and not to Dr. Heitzman, the priority in the discovery of the fibrillated structure of protoplasm. It must be admitted, however, that Dr. Heitzman surpassed all his predecessors in the definiteness and boldness with which he described the reticulated structure of protoplasm.

The existence of a fibrillated structure to protoplasm has been demonstrated during the last few years by several competent observers. Especially on specimens hardened in chromic acid, which Dr. Heitzman prefers, it is by no means difficult for any one, even without a trained eye and without remarkable lenses, to see a reticulated structure in the bodies of many cells. How far the reticulum, demonstrable by chromic acid and by some other reagents, corresponds to structures in the living cell is a question not easily answered. That chromic acid often exaggerates the distinctness with which a reticulum can be seen is certain.

Dr. Welch said that the most satisfactory studies on the structure of cells had been made by Flemming. Flemming, working with the best objectives, such as Zeiss' oil-immersion No. 18, had apparently demonstrated that most, if not all, animal cells have a fibrillated structure of the cell-substance. Whether the fibrils are arranged in the form of a network Flemming had not been able to satisfy himself. Flemming's descrip-

tions and drawings are calculated to inspire confidence by their objective nature, and by the absence of such uniformity of detail as characterize the drawings and descriptions of Dr. Heitzman. It is questionable whether Dr. Heitzman's descriptions apply to the structures seen and depicted by Flemming.

Dr. Welch remarked that the really novel features in Dr. Heitzman's doctrines related to the structure of the nucleus and the pervasion of the basement substance by a network of living matter continuous with that in the cells. In neither of these points had Dr. Heitzman's views been confirmed by competent observers.

There are serious objections to regarding the nucleus simply as an accumulation of the substance composing the cell-body. No histological studies of late years surpass in interest and importance those of Auerbach, Strasburger, Flemming, Hertwig, and others, relating to changes in the nucleus attending cell-division. These observations go to show that the nucleus has a dignity and a function of its own. The nucleus differs from the cell-body by its optical properties, by its reaction to staining dyes, and probably in its structure. A fibrillated structure of the nucleus is often more easily demonstrated than that of the cell-body; but Flemming, who speaks with the greatest authority in this matter, says that on the clearest specimens and with the best optical means, he has never been able to satisfy himself of a continuity between the fibrils in the nucleus and those in the cell-body. He therefore, and it appears justly, rejects Dr. Heitzman's view that there is no difference, except in density, between the nucleus and the cell-body.

Dr. Welch said that the third and the essential point in Dr. Heitzman's doctrine was unconfirmed by competent observers. This point is that the cells throughout the body are connected by a network of living substance which lies everywhere in the basement substance. That certain cells are connected with each other by processes has long been known. In 1870 Bizzozero corrected Max Schultze's error, and established the true relations of the so-called prickly-cells to each other. The anastomoses of other cells, particularly of connective-tissue cells, have also been generally, although not universally, admitted. But it is mainly upon his observations as to the existence of a reticulum of living matters in the basement substance of hyaline cartilage that Dr. Heitzman bases his doctrine. This reticulum he claims to demonstrate by nitrate of silver, chloride of gold, and even to see without the addition of reagents. Dr. Welch said that the silver pictures in general are notoriously difficult to interpret, but even these cannot be satisfactorily produced in cartilage, except near the perichondrium. To base a new scheme of structure of protoplasm, intended to overthrow all previous conceptions of the subject, upon such uncertain pictures, is a bold and unjustifiable proceeding. Dr. Heitzman's views concerning the structure of hyaline cartilage have not been confirmed, or, more strictly, have not been confirmed except in his own laboratory and in that of Stricker in Vienna; and, as he has justly remarked, these laboratories stand alone, as islands in the scientific world. The only original features of Dr. Heitzman's doctrine—namely, the structure of the nucleus and the existence of a network of living substance throughout the basement substance—remain unproved and unaccepted, save in the two laboratories mentioned.

Dr. Welch said that Dr. Heitzman had touched upon several other topics of too wide scope to admit of satisfactory discussion at present. He would, however, say that upon none of these topics was he in accord with Dr. Heitzman. As regards the subject of emigration of white blood-corpuscles, Dr. Welch considered that if anything in pathology was certainly established it was the fact of this emigration, and he doubted whether Recklinghausen would admit that he occupied the same position regarding inflammation as Dr. Heitzman does.

As regards the question of tuberculosis, Dr. Welch

said that there was only one point in Dr. Heitzman's remarks which he would touch upon. Dr. Welch said that Dr. Heitzman was in error when he claimed that inoculation of rabbits and guinea-pigs with various non-tuberculous substances was capable of producing artificial tuberculosis. Cohnheim and Wilson Fox have both retracted the results of their former experiments, and admit, as is generally admitted by the best modern pathologists, that inoculation only with substances containing the tuberculous virus is capable of producing artificial tuberculosis. The experiments and observations of Spina are worthless, and bitter and caustic as was Koch's criticism of Spina, it was justified. Spina's competency is well illustrated by the attempt to produce tuberculosis by inoculation with lycopodium seeds. As might have been expected, each lycopodium seed was the centre of a little inflammatory nodule. But who, besides Spina and Dr. Heitzman, would identify such nodules with a genuine tuberculosis?

The only addition, Dr. Welch said, which Dr. Heitzman had made to this doctrine of the structure of protoplasms, since he had been in New York, was the remarkable statement that by examining the living matter of certain cells he was able to tell the constitution of the individual from whom they came. This addition Dr. Heitzman had not presented fully to the Academy to-night. Dr. Welch would not therefore discuss it, but he supposed that this view could hardly have been seriously advanced by Dr. Heitzman. Dr. Welch protested against Dr. Heitzman's assertion that his peculiar doctrines had been widely accepted in America, and this protest was needed when it was asserted in certain German journals that it was only in America that such views could gain credence.

DR. L. ELSBERG, before discussing the subject, asked Dr. Heitzman concerning Virchow's views with reference to his theory, as he had been quoted for and against it.

DR. HEITZMAN replied that Virchow said he would put arms to the ground only when it is proven that the basis substance has the same physiological dignity as the cells proper, which he (Virchow) did not accept as yet demonstrated.

DR. ELSBERG then said that two years ago he presented to the Academy the results of investigations made with hyaline cartilage, especially in a case where he had examined the hyaline thyroid cartilage of a man forty-eight years of age that had simply been hardened in chronic acid, and showed not only connecting filaments between the cartilage corpuscles, but within the inter-corpuscular space accumulations of matter which were proved to be essentially of the nature of living matter, and the same as that contained in the corpuscles themselves. He would not object to the name cell, provided it was accompanied by the explanation of its real nature; but if it had been proved that it was not a cell, in the sense in which the term had been employed, he thought the word might as well be abandoned. After all, as long ago had been maintained by Fletcher, there are only two kinds of matter in the human body, the living and the non-living. Living matter, however, is not simply vital force added to an otherwise non-living substance, but a matter endowed with all the manifestations of life which are due to this peculiar matter, call it protoplasm, bioplasmon, or what not, and the main points on which Dr. Heitzman's views and the cell doctrine really diverge are the real points as to whether the view of those who maintain that the living properties pervade every portion of the organism to which life can be ascribed is true or not.

DR. HEITZMAN, in closing the discussion, directed attention to the fact that as far back as 1839 the reticulated structure of epithelium had been very well illustrated. The question was not who saw it first, or whether or not there is a reticulum, but his observations had been such as showed that the protoplasm is living matter. He

had not claimed any priority, but Theodore Eimer had claimed it for him, and all Dr. Heitzman wished to show was that to-day the best microscopist in Europe, S. Stricker, has acknowledged the correctness of the claims he made in 1872 and 1873.

The Academy then adjourned.

Army News.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from December 15 to December 22, 1883.

CAMPBELL, JOHN, Lieutenant-Colonel and Surgeon. Having completed the duties pertaining to the office of the Medical Director of the late Department of the South, to proceed from Newport Barracks, Ky., to New York City, and assume the duties of Attending Surgeon in that city. S. O. 284, par. 12, A. G. O., December 12, 1883.

CLEMENTS, BENNETT A., Major and Surgeon. Relieved from duty as Attending Surgeon, New York City, and detailed as member of Army Medical Examining Board, now in session in New York City. S. O. 284, par. 12, A. G. O., December 12, 1883.

WILLIAMS, JOHN W., Major and Surgeon. Leave of absence on surgeon's certificate of disability granted in S. O. 157, November 12, 1883, Department of the Columbia, extended five months on surgeon's certificate of disability. S. O. 286, par. 6, A. G. O., December 14, 1883.

LIABILITY OF SHIP-OWNERS FOR MEDICAL ATTENDANCE.—A very important decision, relating to the liability of ship-owners for medical assistance to sailors injured on shipboard, has recently been given by the Supreme Court of Pennsylvania, and a full account of it is given in the *Maritime Register*. It was an appeal from the Court of Common Pleas, Philadelphia, and the judgment of the lower court was affirmed. It appears that the engineer of a tug-boat lying alongside a wharf, was severely scalded by a burst of steam from the cylinder head. Medical assistance was immediately summoned, and the injured man was, at his own request, taken home, instead of to the marine hospital, to which place the master of the tug offered to take him. The tug-boat owners were called upon to pay for medical attendance to the engineer, but refused upon the plea that the marine hospital service was offered to the man, and his refusal to accept it absolved the vessel owners from any liability for such attendance. This plea would by many ship-owners be held well taken. But the lower court decided

against it upon the ground that the acts of Congress relative to the marine hospital service “do not supersede the right of the seamen, under the general maritime law, to be cured at the expense of the ship to which they belong, of all sickness or injury occurring to them while in the service of the ship.” The Supreme Court takes the same view. The liability of the ship for medical attendance to sick seamen is well settled. The tug-owners claimed, however, that the ship is not responsible if the seamen be taken home from the vessel, that the sailor should remain with his ship, and that if he is removed he cannot of his election choose for his recovery whatever place he may wish. This would leave the election as to place with the ship-owner—a position which is untenable. Upon this point and upon that relating to medicine-chests and medical attendance on shipboard, the Supreme Court gives an opinion which is good law, and what is better, good sense. In the first place it shows that a seaman, for injuries incurred in its service, is entitled to be cured at the expense of the ship. It further points out the fact, which ship-owners often overlook, that hospital dues collected for the support of the marine hospital service are paid by the sailor himself, and have really nothing whatever to do with the ship. A sailor is entitled, upon proper application, to free hospital service, but that is not a service furnished by the ship-owner. The sailor can take it or not as he elects. It is a wise provision which the law has made compulsory upon him, not upon the ship-owner. It is not a provision made by ship-owners “in relief of their liability under law maritime.” The maritime law protects the sailor in all the seas and seaports of the world. The marine hospital service is confined to some few of our home ports. The several acts of Congress relating to hospital dues are, therefore, only auxiliary to the ancient maritime law giving injured seamen the right to be cured at the expense of the ship, and simply afford seamen an additional safeguard. This view is generally adopted by the courts.

CHLOROFORM NARCOSIS INDUCED DURING NATURAL SLEEP.—Dr. H. Culbertson, retired Assistant Surgeon, U.S.A., of Zanesville, O., reports the following case : “Early last September I was called by Dr. A. Ball, of this place, to see a child two years of age, which had, the day before, incurred an extensive lacerated wound of the right cornea at its lower and inner margin. The iris was enclaved in the cut. Dr. E. A. Hildrith, of Wheeling, W. Va., was present. The child was asleep when we arrived, and nothing had been given to induce somnolency. It was proposed to chloroform without awaking the child. Dr. Ball did this successfully by holding the chloroform upon a napkin about eight inches from the child's face, and gradually approaching the inhalant to the face as long as the patient did not move, withdrawing it when it stirred to the original distance, and then gradually approaching again, until finally, bringing it close to the face, it no longer moved, and in ten or fifteen minutes complete narcosis was secured, when the enclaved iris was drawn out, excised, and the eye bandaged. When we departed the child was still asleep, but awoke half an hour later.”

A CASE OF SPINA BIFIDA WITH THE LARGEST TUMOR ON RECORD.—Dr. M. D. Briggs, of Belle Plaine, Iowa, writes : “On the 2d of November last I was called to see the child of Major J—. On arriving I found an infant of ten months burdened with an immense growth springing from the lumbar region, the entire left buttock and hip, and from the upper portion of the posterior aspect of the left thigh. It was a large sac distended to its utmost capacity with a straw-colored fluid. Of course the diagnosis and prognosis were not difficult to make. I only report it as interesting on account of the great size of the tumor, which measured *thirty inches in its longest circumference and twenty-six inches in the transverse*. In all the literature to which I have had access

I cannot find an account of any such growth that even approximates it in size. I endeavored to have it photographed, but could not obtain the consent of the parents. It was already ulcerating at the most dependent portion. In a few days it ruptured with a fearful gush, and in five days the child died from meningitis. A post-mortem could not be obtained.—The growth was about the size of an orange at the time of birth."

A FATAL CASE OF INVERSION OF THE UTERUS DUE TO TRACTION ON THE CORD.—Dr. Geo. Huntington, of La Grangeville, N. Y., gives an account of a case which bears an instructive lesson. He was called to attend a woman in labor, but as she lived some distance off, the labor had terminated and the woman was dead before he arrived. It seems that she had been attended by an old colored midwife who, after the birth of the child, had made such traction on the cord that the uterus was inverted. Great hemorrhage occurred, and the woman died within an hour after delivery. "The case shows," writes Dr. Huntington, "two things: one being the danger that country women more especially run by entrusting their lives to ignorant old women, who doubtless mean well, but whose ignorance often leads them to do irreparable mischief; and the other, that forcible traction on the cord is dangerous and should never be resorted to."

TWO UNUSUAL PARTURITIONS.—Dr. L. Byron Dawley, of Seneca Falls, N. Y., relates the history of an unusual parturition, but which, though rare, was almost exactly like one reported by Dr. W. H. Borham in the *Lancet* last August. Dr. Dawley says: "I attended, October 2, 1881, Mrs. C——, aged twenty-seven, Irish, well made, fair woman, the mother of one child born at full term. Had been in labor about four hours when I got there. As I entered the door I heard very loud cries, and heard her say, 'There, it has come.' I went as soon as possible to the bedside, and on lifting the covering, to my great surprise, found the placenta, membranes, waters, and child all intact. The child was floundering about in the liquid, trying to free itself. I lifted the mass, and to my much greater surprise found that the membranes did not rupture. I then tried them with my fingers, but finally had to resort to the scissors. The child, a female, was quite small, but lived, and is a smart child to-day. The mother made a good recovery." In Dr. Borham's case the patient was also a fair-complexioned, well-made woman aged twenty-eight. The child, membranes, and placenta came away together, the child being alive and the membranes unruptured.

AN ANTIPESSARIST.—Dr. J. Mathews Duncan is responsible for the following outburst: "In the present great abundance of contorted bits of wood, and metal, and vulcanite, and what not, called pessaries, my advice to you is *Punch's* advice to a young man contemplating marriage—Don't! Think twice before beginning the often baneful practice of using any instrument, teaching a woman to depend on what, if not positively useful, is positively injurious, though perhaps not much so. Many a woman has suffered from, and many a woman has died of, a pessary; but most pessaries, as I find them in use, are nearly innocuous for evil or for good. They are always harborers of dirt, and they always keep the mind watching the part; they are all liable to decay, and require, if long used, to be renewed. They are all undesirable additions to the contents of the pelvic excavation, and, if they are efficient, must, of course, cause more pressure, though perhaps on different parts, than that caused by the organ or organs which they keep in an altered position. Curious things are anteflexion pessaries. In regard to their giving relief I express no opinion, but I do say that if they give relief it is not by undoing the flexion, and keeping it undone, keeping the womb straight. I have seen most kinds of anteflexion pessaries as placed by their inventors, and too often replaced and replaced, but I have never seen one materially modify the flexion. I have myself never used one, and have no intention of doing so. There is another bad and too

common practice which I must not omit to mention here, that is, what is called straightening or putting up the womb, or replacing it time after time by the probe or finger. This has no other effect than to irritate the organ, for the displacement recurs immediately after the probe or finger is removed, as the practice itself shows."

A CASE OF KEROSENE POISONING.—Dr. C. S. Wheeler, of Williamsburg, Mass., sends us the history of a case of kerosene poisoning, which is instructive, as these accidents are rare. He says: "I was called October 29th to see a child, eighteen months old, who had swallowed an unknown quantity of kerosene, though the amount probably did not exceed two ounces. The little patient, seen one hour subsequent to the swallowing, was vomiting, purging, cyanotic; a tendency to coma existed, the pulse was 130, weak, and somewhat irregular; respiration was also irregular. Treatment: ordinary emetics were given before my arrival, hence only stimulants and alkalies were ordered. After a few days of gastro-enteric febrile movement the child recovered. I have heard of several ounces of kerosene having been taken by adults without perceptible results, but the above case compels me to doubt the statement."

LET NATURE REMOVE THE PLACENTA.—In the *Deutsche Med. Wochenschrift* Dr. Dohrn thus sums up his experience: "1. In one thousand lying-in women, in whom the expulsion of the placenta was left to nature, the results were far better than in one thousand others in whom Credé's method of expulsion was used. 2. The one thousand lying-in women in whom the placenta was spontaneously expelled had considerably less hemorrhage and fever after delivery. In those cases treated by Credé's method portions of the membranes were frequently retained, and there were more fatal cases than in the others. 3. The disadvantages which are conditional to the method of Credé are especially seen in the cases in which the placenta is expressed during the first five minutes. After a longer time the expression was more complete, but never as safe as by the spontaneous method."

AMERICAN PROFESSORS.—America's contributions to science are by no means very extensive, or very often important, that is, as compared with the great volume of German production, in which comparison they seem almost insignificant. We have never duly fostered research, for we have bestowed upon it neither the proper time nor office. There are, we suppose, at least six thousand "professors" in the United States. Are there one hundred and fifty of them active investigators? The time seems remote when every American professor will be expected to be also an investigator, or to contribute aught to the common fund, but among us is a little band of men who have before them the model of Germany, and who are earnestly working for the intellectual elevation of their country. The first object is necessary to render research more important in public estimation, and so to smoothe the way for a corps of professional investigators. Every thoughtful person must wish success to the attempt.—*Science*.

MEDICAL SUPPLY AND DEMAND.—Statistics show that among 1,000 doctors the number of deaths annually ranges between 15 and 25. At this rate the number of deaths annually among the 90,000 medical men of this country would be on an average 1,800. Among the 14,000 physicians of Austro-Hungary the annual death-rate is said to be about 320. If the same ratio existed in this country, the number of deaths annually would be slightly over 2,000. Probably the actual figure is not far from 1,800. On the other hand, the number of medical graduates in 1882-3 was 3,979, or nearly four thousand, and more than double the estimated number of deaths. Account must be taken of the number of physicians who annually retire from practice, and on the other hand of the number of graduates who never enter the practice of medicine. The annual increase of population is probably over a million.

 Baruch, Dr. Simon, malaria as an etiological factor in New York City, 505.
 Bath, the permanent, in surgical diseases, 262.
 Battey's operation, antiseptic in, 348.
 Basedow's disease, 183.
 Bauer, Dr. Joseph L., the relation of perinephritis and pyonephrosis to morbus coxæ, 623.
 Beard, the late Dr. George M., 399.
 Bed-sores, 196.
 Beriberi, 544; and myxœdema, 262.
 Bermingham, Dr. Edward J., notice of book edited by, 415.
 Bichat and the doctrine of vital properties of the tissues, 600.
 Bigelow, Dr. Horatio R., notes on gynecological therapeutics, 452.
 Bile, action of alkalies on, 239; action of mineral waters and of hot water on, 504; secretion of, 655.
 Biology, 640; progress of, in Europe, 715.
 Birth after death, 16.
 Bismuth, salicylate of, in typhoid fever, 157.
 Bladder, divided by a septum, 17; tumors of, 376; wounds in, 184.
 Blakeman, Dr. W. N., 531.
 Bleeding, a novel method, 476.
 Blepharoplasty, 109.
 Blepharospasm, 63.
 Blindness, from retinal thrombus, 108.
 Blisters in the treatment of rheumatism, 620, 696.
 Blood, hypodermic injection of, 239; legal value of, 74; new theory concerning the circulation of, 137; of beef, powdered, as an alimentary principle, 296.
 Blood-corpuscles, new property of the, 38; the third, 95.
 Blood-vessels, of the spinal cord, 38.
 Bly, Dr. Myron T., early English medical and surgical legislation, 235.
 Board of Health, Louisiana, notice of annual report, 442.
 Books, or backgammon, 42.
 Borschein, Dr. L. E., chloroform narcosis during sleep, 23.
 Bradnack, Dr. F., 448; the Elisabethan dramatists and later poets on the principles and practice of physic, 191.
 Brain, concussion of, in a young child, 625; contusions of, 123; derangement of the muscular sense in disease of the, 9; nail imbedded in, 306; recovery after passage of a ramrod through, 293.
 Breast, cancer of, 635; syphilitic disease of, 91.
 Brechin, Dr. W. P., large infants, 707.
 Briddon, Dr. Chas. K., cases in abdominal surgery, 393.

Briggs, Dr. M. D., spina bifida, 717.
Bright's disease, new theory concerning the nature of, 128.
British Medical Association, 126, 130.
Bronchitis, chronic, 121.
Brose, Dr. Louis D., tuberculosis as produced by sprayed sputa, 563.
Browne, Dr. Valentine, a perfectly developed male child without a placenta, 24.
Brush, Dr. E. F., can measles occur five times in the same patient within three months? 529.
Buchanan, Dr. J. J., 232.
Bulkley, Rev. Dr., and Newton, the healer, 519.
Burch, Dr. T. Hamilton, application of powder to the post-nasal region, 53.
Burke, Edward, 548, 577.
Burke, Dr. Martin, cholo-cystotomy with recovery, 515.
Burnett, Dr. Charles H., mastoid disease, 229.
Burrall, Dr. F. A., 531.
Burrill, T. J., notice of monograph by, 190; new method of staining bacilli, 651.
Bycycling, therapeutic value of, 642.

C

Calcium sulphide in croup, 377.
Calculi, urethral, 489.
Calculus, cutaneous, 111; in etiology of intestinal obstruction, 376; vesical, rectal examination for, 212.
Calhoun, Dr. Chas. W., notice of death of, 81.
Calomel, and micro-organisms, 162.
Canaliculus of the lower eyelid, 162; tear-stone in, 289.
Cancer, 147, 346; in cattle, 447; new method of diagnosing, 306; of the breast, 635; of the œsophagus, 635; of the penis, can it be acquired by inoculation from cervix uteri? 547; of the stomach, liver, and kidneys, 470; propagated by sexual intercourse, 532;
Capillaries, biliary, 161; blood, inoculation of, 196.
Carcinoma, 217.
Carpenter, Dr. James Stratton, tartar emetic poisoning, 401.
Carroll, Dr. A. L., 334.
Case, Dr. Meigs, injury of the forearm, 706.
Castle, Dr. F. A., copper and cholera, 222.
Castor bean, poisonous properties of, 82.
Cataleptiform state, post-mortem, 293.
Cataplasmata, in the treatment of lymphosarcomata, 295.
Cataract, Förster's operation for immature, 118; improvements in instruments for operations, 102; ripening of, 107; Taylor's method of extracting, 192; thirty-five cases of extraction, 104.
Catarrh, American, 364.
Cathell, Dr. D. W., notice of book by, 356.
Catheter, red soft, danger attached to the use of, 498.
Catheters, 196.
Cattle quarantine, New York, 612.
Cats, prophylactic use of, 448.
Caul, value of, 540.
Cephalalgia, 349.
Cerebellum, probable tumor of, 36; the architecture and functions of, 449, 485.
Cerebral acts, rapidity of, 11; complications in aural diseases, 337; exhaustion, 610.
Cerebrum, derangement of muscular sense in disease of the, 9; functional independence of the hemispheres, 193.
Cerebro-spinal fever, 559.
Cerumen, removal of from the ear, 599.
Chalmers, Dr. G. S., goitre, 390.
Chancre of the tonsil, 124; treated by heat, 362.
Chapin, Dr. Henry D., chorea, 648.
Charlatan, derivation of the word, 446.
Chauffage, in venereal disease, 123.
Cheesman, Dr. W. S., 335.
Chekau, 256.
Chew, Dr. S. C., acute atrophy of the liver, 369.
Child, well developed without a placenta, 24.

Child-bearing, late in life, 639.
Children, the growth of, 139.
Chills following intra-uterine injections, 654.
Chinese, medical notions among, 641.
Chloral, croton, in pertussis, 376.
Chloral hydrate, as an adjuvant to cathartics, 224.
Chloral hydrates, the, 146.
Chlorides, urinary, 516.
Chloroform, and carbonate of ammonia in labor, 620; death from, 244; in labor, 388; internally administered, 377; local anæsthetic action of, 683; narcosis during sleep, 23, 55, 112, 280, 454, 465, 613, 717; sudden death from, 124.
Cholera, 14, 44, 73, 97, 160, 187, 215, 268, 468, 689; adynamic theory of, 377; and collodion, 265; and copper, 190, 222; and England, 264; and pilgrimage to Mecca, 240; commission in Egypt, 547; in Egypt, 300; micrococci of, 354; pill as prophylactic, 354; report of French Commission, 650; treatment of sporadic, 7; report of French Commission, 359; infantum, 331; morbus, benzoate of soda in, 179.
Cholo-cystotomy, 515.
Chorea, 648.
Choroid, 64; coloboma of, 110; melanotic myeloma of, 582; melano-sarcoma of, 75; ossification of the, 107; sarcoma of, 106; tubercle of, 104.
Cigarette smoking, 21.
Circulation of the blood, new theory concerning, 137.
Clamps, artery, 586.
Clark, Dr. Alonzo, 688.
Clark, Dr. D. S., 196.
Cleanliness, in surgical operations, 324.
Cleavers, in chronic ulcers, 68.
Coats, Dr. Joseph, notice of book by, 690.
Code, 436, 438; middle ground, 22; the, and the St. Louis Medical Society, 196; supporters of the old in the State of New York, 74.
